The IR region of the solar spectrum provides important diagnostics for heat transfer processes in the photosphere, where the gravity and acoustic waves which heat the corona originate. Rates of molecule formation and dissociation in these layers are highly temperature sensitive. Recently relative intensities and short-period variations in individual lines of the rotation–vibration band of CO at 4.7 μm (refs 1–3) were obtained with spectral resolution $\nu/\Delta\nu \sim 0.7$–2.1×10^4 (refs. 4, 5) from ground-based sites. High resolution cannot wholly overcome atmospheric absorption problems, so to measure absolute energy and variability in the band we have observed the solar spectrum from the orbital station Salyut 5.

0028–0836/79/410463—02$01.00

The spectrometer for the region 1.8–15 μm used a bolometric detector and a Littrow–Pfund optical layout with an NaCl prism. It was fed by a newtonian telescope of 45 cm focal length with a 19 cm × 24 cm primary, giving a field of view of 4 arc min × 24 arc min as defined by the entrance slit. A typical recording time per spectrum is 4 s. The station served as an inertial observing platform, pointing to within an accuracy of a few arc min; stability was maintained via a solar imaging camera, with 2.5 s between images.

Of the spectra taken on 1, 4 and 5 August 1976 and 16 February 1977 we have chosen 46 from the east–south part of the disk, where independent data[6] showed no solar activity such as spots or flares. The situation is illustrated in Fig. 1. Table 1 shows the timing of the selected groups of spectra.

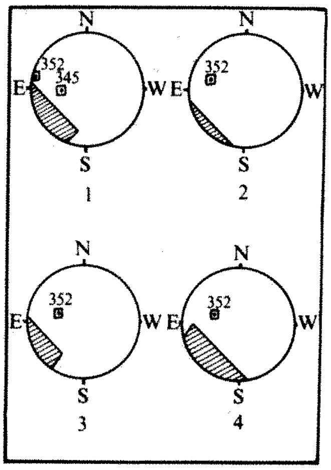

Fig. 1 The hatched areas show the regions on the solar disk on which the four groups of experiments were directed. ⊡, The regions of solar activity during the experiments.

Figure 2 shows the results of averaging each group of spectra in the wavelength range 4–6 μm where variability was observed. Between 4.05 and 5.25 μm there are excesses: for series 3 of 3%, for series 2 of 8% and for series 1 of 13% compared with the minimum curve of series 4. The r.m.s. error in the data is between <1% and 2%. An estimate of systematic error was obtained from data with the slit 3 arc min from the solar limb, when a signal value of 1% was registered. Guidance errors are 1 arc min maximum, and scattered light was minimised by diaphragms at three pupils: the spectrometer slit, the output slit and the bolometer. We can thus assert that the observed CO

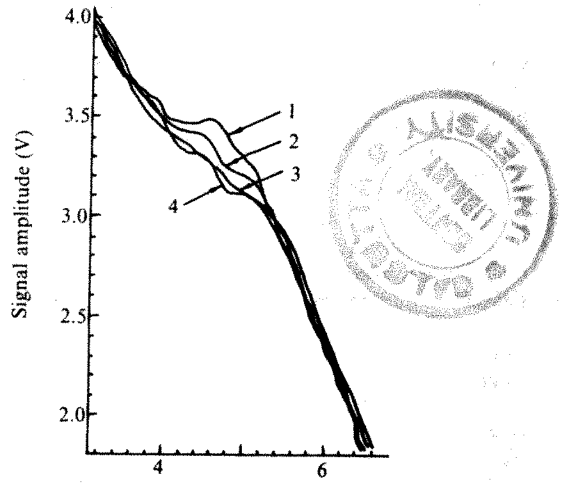

Fig. 2 Spectral dependence of a signal at the spectrometer output for the experimental groups 1, 2, 3 and 4.

Table 1 Timing of the 46 selected spectra

Series	Orbit no.	No. of spectra	Date (August 1976)	Time duration	$F_{\odot}$(2,800 MHz) (Wm^{-2} Hz^{-1})
1	640	24	1	11 h 21 min 40 s–11 h 23 min 20 s	75.9×10^{-22}
2	685	6	4	7 36 35 – 7 37 0	82.5×10^{-22}
3	700	6	4	6 43 50 – 6 44 15	82.5×10^{-22}
4	701	10	5	7 23 45 – 7 33 25	84.2×10^{-22}

Timing relates to the spacecraft orbit, and thus bears no periodic relation to the period of solar rotation or activity.

variability is real, and intrinsic to the quiet Sun. Absence of solar activity is indicated by the steady values of the 2,800 MHz radio flux $F_{\odot}$ (2,800 MHz) shown in Table 1. Geomagnetic field perturbations were low (index $A_p \sim 4$–5) and two small Hα flares, shown as 352 and 345 in Fig. 1 do not lie near our observing regions. OSO 8 X-ray data and Mt Wilson magnetograms listed in ref. 6 also indicated no flare activity there.

From previous, resolved spectra of the solar CO band[4,5] one can conclude that the species contributing to the radiative flux are H^- (at an effective temperature of 5,400 K (ref. 7)) and CO (with $T \sim 4{,}500$–4,900 K). The linewidth to separation ratio for CO is 1:10 so the CO absorption cannot be >10% of the continuum in the range 4.05–5.25 μm. An observed variability of 5–10% suggests complete disappearance and re-formation of CO over periods of the order of a few hours. This could be due to convective cycling, in the granules, of hotter material from below.

The observed variability in flux is of the order of 1.3×10^4 W m^{-2}, that is, some 2×10^{-4} of the total flux of solar radiation. Theoretical estimates for the energy flux contained in gravity waves lie close to 4×10^4 W m^{-2} with an acoustic flux of similar order. Thus CO formation and destruction may provide an important sink and source of energy for the maintenance of the acoustic, gravity, and magneto-acoustic waves responsible for coronal heating. Although details must await a more thorough analysis, one can point to suggestive theoretical support for the hypothesis. Theoretical values[8] for the non-radiative component of the energy flux are much greater than the combined fluxes due to X-ray and UV radiation and the solar wind; CO radiation could balance the energy equation. Photospheric thermal relaxation could be affected by the CO radiation, thus affecting the propagation of gravity waves. Concentration changes in CO can enhance photospheric convective instability by changing the radiative temperature gradient. Finally, note that further observations with greatly increased angular resolution could be used to make direct observations relating to the energetics of convective granulation.

We thank Dr J. E. Beckman (Queen Mary College, London) for his considerable help with rewriting this paper.

An estimate of the fine structure constant

S. L. Glashow & D. V. Nanopoulos

Lyman Laboratory of Physics,
Harvard University, Cambridge, Massachusetts 02138

Quantum electrodynamics, despite its many successes, has left many questions unanswered. Why is electrodynamics so different from other interactions? Why do all particles have commensurate electric charges? Why is the value of the fine-structure constant what it is? Today, we have an apparently correct and essentially complete description of all of elementary particle physics in terms of a gauge theory[1]. If the underlying gauge group is simple[2,3], all three elementary particle interactions—strong, weak, and electromagnetic—are parts of one unified theory. (The earlier attempt to synthesise all three interactions obtained both charge quantisation and baryon number violation. It was not based on a simple gauge group, nor did it incorporate conventional quantum chromodynamics.) Electromagnetism is no longer so unique. Apparent differences among the interactions reflect the pattern of spontaneous symmetry breakdown. Charge quantisation is forced on us: all fields have integer mutiples of one-third the electron's charge[2,3]; all observable particles have integer multiples. (We assume that colour is a truly hidden variable, that quarks are fractionally charged and never liberated. For another point of view, see ref. 4.) The fine-structure constant cannot be chosen arbitrarily. For unified theories in which the proton is unstable, we find an upper limit to its strength, $\alpha < 0.04$. We derive this result here and survey the context in which it arises.

0028-0836/79/410464—02$01.00

The minimal gauge group which is required to describe all three interactions is $H = SU(3)\times SU(2)\times U(1)$, not a simple group. Three kinds of quantum fields are needed: gauge bosons, Higgs bosons, and fermions: the 12 gauge bosons include eight gluons (confined, hence not directly observable), three intermediate vector bosons (heavy, hence not yet observed), and the photon. At least one Higgs boson must survive as an observable particle at accessible mass[5,6].

Fermions come in families of 15 chiral fields apiece[7]. (We put the tau lepton and the upsilon-constituent into a third 15-plet, also including a not-yet-seen $Q = 2/3$ quark.) One family—containing up and down quarks, electrons, and electron neutrinos—suffices for a description of most phenomena. There exist at least two additional families. We do not know why all families have the same format, nor why there are three families, nor whether there are more than three. (The $SU(3)\times SU(2)\times U(1)$ representation content of each of the families is identical. Each family is a minimal anomaly-free representation of H. This behaviour survives unification in its simpler forms. Each family is a reducible $10+\bar{5}$ representation of SU(5), or an irreducible spin representation of 0(10). In no plausible scheme do all three families belong to a single irreducible representation.) Each family is supposed to contain a weakly-coupled massless, or nearly massless, neutrino. The number of these that may exist is related to the observed helium abundance in the Universe[8–10], and not many more than three families are tolerable. On the other hand, three is the minimum number of families for which an elegant description of CP violation makes sense[11].

The theory based on the gauge group H and involving three fermion families is not a unified theory. It does not explain charge quantisation. It involves 17 independent dimensionless parameters[12], each as fundamental as the fine-structure constant. Although 17 free parameters must be too many for a fundamental theory to admit, it should be considered that all elementary particle properties can be expressed (in principle) in terms of them. Perhaps the gauge group H is merely the phenomenologically-relevant remnant of a larger and simple unifying group G. The three independent gauge coupling constants are reduced to one, and quantisation of charge is assured. Restrictive hypotheses can yield further relationships among the 17 parameters[13]. Such theories have the following properties: (1) G has more generators than does H. They correspond to a fourth class of gauge boson which mediates new types of interaction. Generally, the new interactions leads to the decay of the proton. (But not necessarily. Unified theories without proton decay exist. A scheme based on $[SU(3)]^3$ with permutation symmetry is an example.) These gauge bosons must therefore be extraordinarily heavy. (2) The value of the weak mixing angle $\sin^2\theta$ can be computed, and the result agrees with experimental determinations.[14] This is the only convincing quantitative indication that unification is correct. (3) An interplay between CP violation and baryon number violation can, during the very early history of the Universe, produce the observed baryon surplus.[15-19] This result requires the existence of a rich structure of Higgs bosons,[20,21] a fact which is confirmed by the observed pattern of fermion masses. For unified schemes based on either SU(5) or O(10), the Higgs bosons which couple to fermions must comprise at least two inequivalent representations. For SU(5), at least a 5-plet and a 45-plet are needed. For O(10), at least a 10-plet and a 126-plet are needed. In either case, the Higgs sector is then rich enough to provide the baryon surplus.

The superheavy unification mass may be estimated in two ways. Strong interactions are asymptotically free, so that the strong gauge coupling constant decreases with increasing energy. The fine-structure constant slowly increases. The point of convergence of the coupling constants dictates the unification mass. We obtain $\sim 10^{14}$ GeV assuming that we have correctly identified H as the entire phenomenological gauge group[22,23]. The existence of baryon-number violating interactions must soon reveal itself.

An alternative estimate of the unification mass does not depend on the details of particle phenomenology. It follows from the present lower limit on the proton lifetime of 10^{29} yr (ref. 24). This assures us that the mass M of the baryon-number violating intermediary must be $\geqslant 10^{14}$ GeV. It also provides our upper limit on the strength of the fine-structure constant. We have noted that electromagnetism is not asymptotically free. The fine-structure constant depends on energy according to[25,26]

$$\alpha^{-1}(0) = \alpha^{-1}(M^2) + \frac{2}{3\pi}\sum_f Q_f^2 \ln\left(\frac{M_W}{m_f}\right) + \frac{1}{18\pi}[32F-63]\ln\left(\frac{M}{M_W}\right)$$

Where $M_W \simeq 85$ GeV is the intermediate weak vector boson mass, Q_f and m_f are the charge and mass of the fermion f, and F is the number of families ($F \geqslant 3$). For this analysis to be sensible, $\alpha(M)$ is assumed to be <1. It follows that $\alpha(0)$ must be quite small. Since M is known to be $>10^{14}$ GeV, one obtains the constraint, $\alpha^{-1}(0) \geqslant 25$. In any unified scheme in which the proton decays (but not too quickly), and for which perturbative estimates are reliable, the fine structure constant cannot be large. To a greater extent than was imagined, things must be as they are.

Direct observation of the structure of a metallic alloy glass

P. H. Gaskell & David J. Smith*

Cavendish Laboratory, University of Cambridge

C. J. D. Catto & J. R. A. Cleaver

Department of Engineering, University of Cambridge, Cambridge, UK

Under favourable circumstances, high resolution axial bright-field transmission electron micrographs can provide information on the medium-range structure of oxide glasses and amorphous semiconductors[1]. Specifically, the presence in an image of localised patterns of fringes, with the fringe spacing related by Bragg's law to the first diffraction peak, provides evidence of correlations in atomic positions over distances in the range 8–15Å. 'Amorphous lattice fringes' with these characteristics have been studied in many amorphous solids but hitherto have not been reported in glassy metals, although several attempts have been described previously[2-4]. We present here what we believe to be the first high resolution axial, bright-field micrographs with lattice resolution of an amorphous metal, taken with the Cambridge University 600 kV high resolution electron microscope (HREM)[5]. The image features obtained indicate that it is now possible to observe directly the microstructure of amorphous metals, thereby emphasising the potential of high resolution microscopy as a tool for furthering the understanding of the structure of amorphous metallic glasses.

A bright-field electron micrograph provides a representation of the atomic density of the specimen projected onto a plane normal to the electron beam. The image contrast corresponding to a Fourier component of the specimen with period Λ is the product of the scattered amplitude, represented by the square root of the structure factor and the instrumental response function. The form of the latter, commonly known as the contrast transfer function, depends on the aberration constants of the objective lens and the electron wavelength, λ. It is controlled in practice by the strength of the objective lens, as characterised by a defocus parameter[6] and modulated by envelope functions which represent the effects of non-monochromaticity of the incident electron beam and non-parallel illumination. Thus the contrast transfer function, $T(Q)$, is a damped oscillatory function of spatial frequency, $1/\Lambda$, with an amplitude which decreases rapidly for $\Lambda \leqslant 4$Å for an accelerating voltage of 100 kV, as shown in Fig. 1*a*. However, by using a very strong objective lens, it is possible to extend the CTF to better than 2Å although reversals in contrast make image interpretation difficult[7].

For crystalline specimens, the structure factor, $S(Q)$ (where $Q = 2\pi/\Lambda$) consists of a series of intense peaks sharply localised in reciprocal space. Consequently, even though the magnitude of $T(Q)$ may be very low, it is often possible to arrange that

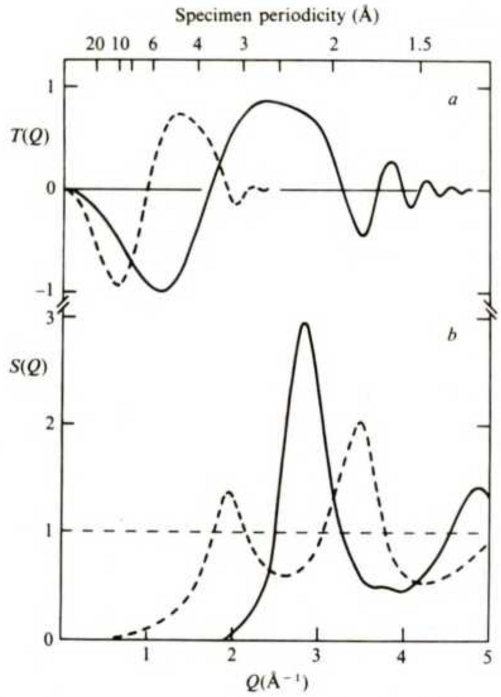

Fig. 1 *a*, Typical contrast transfer functions for electron microscopes with accelerating voltages of 100 kV (dashed line) and 500 kV (solid line). These functions are plotted for a generalised defocus value (see ref. 6) of $D = 3^{1/2}$ and with chromatic (C_c) and spherical (C_s) aberration coefficients, appropriate to typical 100 kV microscopes ($C_c = C_s = 1.8$ mm) and to the Cambridge HREM ($C_s = 3.27$ mm, $C_c = 3.33$ mm). *b*, Structure factors for *a*-Pd_4Si taken from neutron scattering data[10] (solid line) and for *a*-Ge (X ray)[11] (dashed line).

$T(Q)$ is effectively constant over the width of the peak, and that the product $T(Q) \times S(Q)^{1/2}$ is large enough for lattice fringes of adequate contrast to be observed. The intensity of the first diffraction peak for any amorphous solid is much lower than that for a crystal, and the peak is characteristically diffuse—an 'amorphous halo'. As a direct result, faithful reproduction of any periodicities in amorphous solids generally presents more difficulties and, especially at high spatial frequencies, makes extreme demands on the performance of the microscope.

To observe 'lattice' fringes in an amorphous solid, it is apparently necessary to arrange that $T(Q)$ is maximised at Q_p, corresponding to the first peak of $S(Q)$, and that a broad peak, or lobe, of the contrast transfer function, encompasses a significant fraction of the first diffraction halo[8]. For materials such as amorphous silica, carbon, germanium and silicon, $Q_p = 1.5$–2.0 Å^{-1}, these constraints can be met at 100 kV by arranging that the second or third lobe of $T(Q)$ shall coincide with Q_p. Observation of the image at 100 kV becomes almost impossible for amorphous metallic alloys with $Q_p \sim 2.8$ Å^{-1} corresponding to 2.3 Å periodicities. At such high spatial frequencies, $T(Q)$ is effectively zero, unless the spherical aberration constant of the objective lens is very low, and normally oscillates several times (giving alternate positive and negative contrast) over the width of the diffraction peak.

The shorter electron wavelength corresponding to the higher accelerating voltage (up to 0.6 MV) of the Cambridge University HREM effectively extends $T(Q)$ to higher spatial frequencies by a factor approximately proportional to $(\lambda_{500}/\lambda_{100})^{1/2} \simeq 1.6$ (ref. 9). For an accelerating voltage of 500 kV, $T(Q)$, in optimum conditions, now extends beyond $Q_p \simeq 2.8$ Å^{-1} (see Fig. 1*a*) so that the direct observation of any fringes present in amorphous metals becomes practicable. Moreover, as Fig. 1*b* shows, amorphous metals possess an important characteristic which militates in favour of clearer lattice images. Whereas the first peak of $S(Q)$ is almost invariably weak in amorphous semiconductors and oxide glasses, the first peak in amorphous Pd_4Si is strong. Also, the absolute value of the scattered intensity—proportional to the square of a weighted sum of the atomic scattering factors—is typically more than five times larger than that for amorphous carbon. Consequently, the ratio of signal from an amorphous metal foil to noise from a carbon support film, or from a layer of contamination, may be acceptably high even for very thin specimens. This is of considerable importance since any ordered domains in amorphous solids would be expected to be smaller than 15–20 Å (on the evidence of both diffraction data and dark-field microscopy). Clearly, contrast is maximised for foils of thickness near 15 Å and decreases rapidly with foil thickness thereafter, due to overlap of domains which may not be Bragg-orientated and which thereby add to the background noise.

Thin foils of a palladium–silicon alloy were prepared by flash evaporation of a crystalline alloy from a tungsten spiral onto freshly cleaved rock salt at 20 °C at a pressure of around 2×10^{-5} torr. (Other foils have been prepared by evaporation onto liquid N_2-cooled substrates at a lower pressure and these give qualitatively similar image features.) Several films of different composition were prepared and specimens selected which were amorphous, as judged by electron diffraction and confirmed by dark-field microscopy which revealed no large speckle. The composition of the foil is not known with certainty—there seems to be some loss of silicon during the flash evaporation process, but since the specimen chosen lies at the high-silicon end of the range of amorphous specimens, it was judged to contain 20–25 at. % Si. Examination at 100 kV showed that the films had a droplet morphology with particles appearing to be supported on a very thin amorphous film (silicon

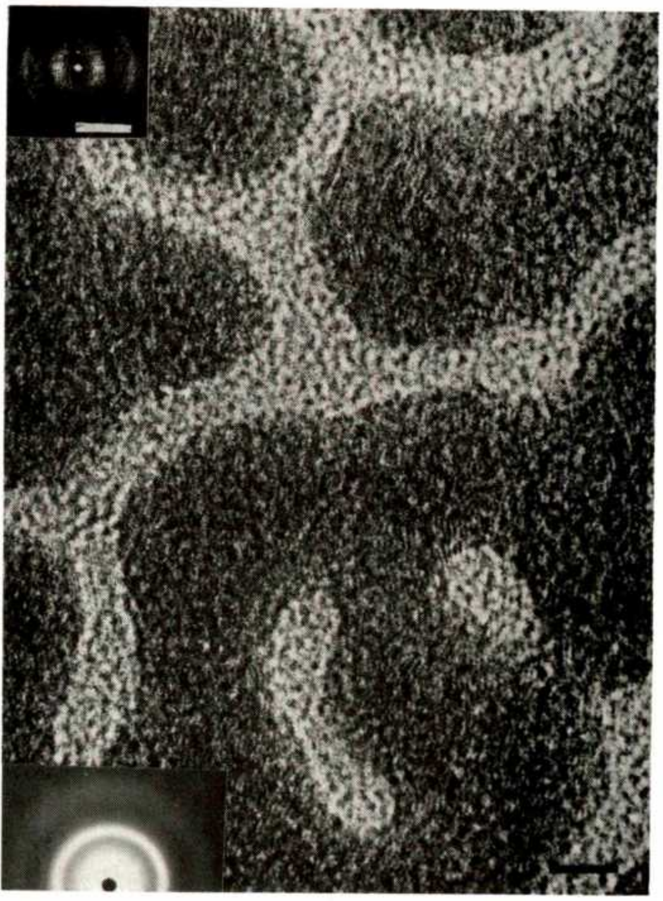

Fig. 2 High resolution image of an amorphous palladium–silicon alloy, recorded with an accelerating voltage of 500 kV. Fringe structure with a periodicity of about 2.3 Å is seen, especially in thin regions near the edge of the particles. Scale bar, 25 Å. Insets show the image power spectrum (marker represents (2.3 Å)$^{-1}$) obtained by computer processing (upper left) and the electron diffraction pattern (lower left).

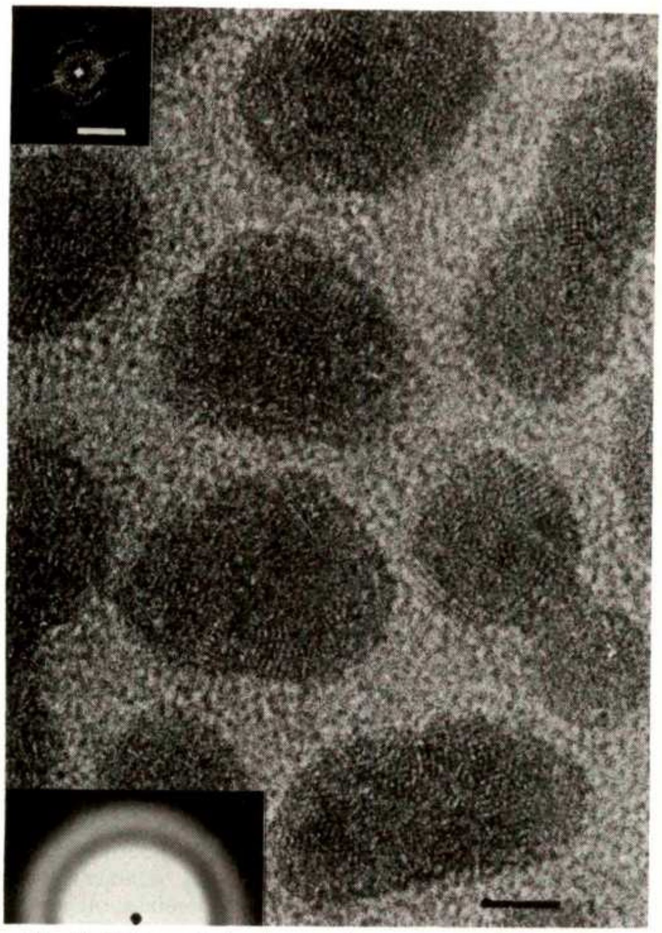

Fig. 3 High resolution image of amorphous palladium–silicon recorded in similar conditions to Fig. 2. The particles are smaller than those shown in Fig. 2 so fringe detail is more prominent.

dioxide). Some 4 Å structure was observed in this film but no high frequency detail was visible in the particles.

High resolution images recorded at an accelerating voltage of 500 kV show fringe-like features with a spacing of about 2.3 Å in the metal particles. In thicker specimens (Fig. 2) detail is most obvious, as expected, near the edge of the particles; at the centres, the structure gives the impression of randomness. Contrasting fringes are rarely seen, and then only over relatively small areas. The thickness profiles have not yet been determined, but assuming a circular cross-section, particles would be from 40 to 80 Å thick at their centres. It seems likely that the disappearance of fringe structure in the centre of particles is directly related to the overlap of Bragg-orientated regions with other, incorrectly-orientated domains.

Fringes are much more prominent in thin specimens, as evidenced by the image shown in Fig. 3. This specimen was evaporated at the same time as the thicker sample, with the thickness being varied by increasing the source–substrate distance. Although it is possible that this foil may have an essentially different structure from the thicker specimen it seems unlikely and the more pronounced structure is probably an effect of thickness. Only rarely do parallel fringe systems extend more than 20 Å in a given direction and the general impression gained from this micrograph is that each particle contains several fringe systems, some of which appear to be related by twin planes. In this sense, the particles seem to be similar to multiply-twinned particles in which lattice fringes are, however, more prominent, as identifiable multiply-twinned particles are often large and symmetrical (pentagonal or icosahedral) structures.

The fringe structures observed in Figs 2 and 3 show similarities to those seen in oxide glasses and amorphous semiconductors, in that parallel fringes are confined to local regions and the contrast is lower than that observed in single crystals of similar size. There are, however, significant differences. Fringes are not only parallel but tend to be straight, in contrast to the curved fringes often seen in oxide glasses. Moreover, the area over which fringes are seen often exceeds 100 Å^2. The electron diffraction patterns (insets in Figs 2 and 3) show the classical amorphous structure which does not appear to change with irradiation in the electron beam. Furthermore, diffraction patterns were recorded without any change of the illumination conditions from those used in first obtaining the micrographs (that is with a relatively weakly convergent beam), thus removing the possibility that the diffracted intensity from any electron-damaged region was swamped by the intensity scattered by the surrounding, unirradiated area. These figures display, perhaps more clearly than similar high resolution micrographs of amorphous semiconductors, that a locally ordered structure is not necessarily inconsistent with the impression of randomness beyond, say, 10 Å suggested by the diffraction information. The latter is an average over a specimen volume many orders of magnitude larger than that of the locally ordered domains observed in this film. A minimum conclusion appears to be that this specimen of amorphous Pd–Si possesses at least as much order as the oxide glasses and amorphous semiconductors. However, these micrographs are also inconsistent with any simple microcrystallite model.

Do the fringes necessarily imply localised order in the metallic glass? The possibility that statistically random fluctuations in a structureless medium could be imaged as fringes has been examined by several workers. Furthermore, periodic oscillations of the projected atomic density have been observed for certain orientations of (nominally) random models of amorphous metals[12]. It is not possible to relate these 'pseudo-lattice' fringes to those observed experimentally except by careful computation of axial images. Calculations by Cochran[13] and Krivanek[14] suggest, however, that fringe-like regions with projected areas as large as those shown here are unlikely to arise by chance overlap of atoms in a truly random array.

Note that the results described here relate to a single example of an amorphous alloy, and that this specimen requires more adequate characterisation. Moreover, the electron diffraction technique is one of the least accurate for obtaining even semiquantitative scattering information. Examination of a more representative range of compositions is needed before the conclusion can be drawn that these specimens, with their relatively ordered medium-range structure, are typical of the whole class of amorphous metals. However, these results clearly reveal the potential of high resolution electron microscopy as a technique for examining the structure of rapidly quenched amorphous alloys. It should also be useful in studies of the puzzling low-temperature precrystallisation phenomena which have a drastic effect on the physical properties of many amorphous metals, and for following the rather complex series of crystalline transformation.

The Cambridge University 600 kV HREM has been constructed with major financial support from the SRC, to whom we are also grateful for individual support. P.H.G. acknowledges support from Pilkington Bros Ltd and from the SRC through a senior fellowship. We thank Drs V. E. Cosslett, W. C. Nixon and their colleagues, Dr A. Howie and Dr W. O. Saxton (who produced the power spectra shown in Figs 2 and 3) for helpful discussions.

Control of seawater composition

D. R. Turner & M. Whitfield

Marine Biological Association of the UK,
The Laboratory, Citadel Hill, Plymouth, UK

We have previously discussed[1] the correlations between the seawater/rock partition function K_Y(sw) (mean concentration of Y in seawater/mean concentration of Y in crustal rock) and the electronegativity function $Q_{YO}[=(x_Y-x_O)^2$ where x is the electronegativity of the subscripted element][2]. The parameter Q_{YO}, which is a measure of the ionic interaction between the element Y and oxygen, was used to extimate the tendency of Y to become incorporated in the oxide-based mineral lattices which constitute most marine particulate matter. The nature of the correlations between K_Y(sw) and Q_{YO} (Fig. 2, ref. 1) led us to suggest that the partitioning of an element between seawater and crustal rock is controlled predominantly by its solid state chemistry with solution chemistry playing a secondary part. More recent estimates of the composition of mean world river water and mean crustal rock[3] significantly improve the correlations described earlier and provide fresh data on the concentrations of the lanthanides in these reservoirs. Here we compare the chemistry of the lanthanides with that of alkali and alkaline earth metals with a similar electronegativity (the 'lithium group' Li, Mg, Ca, Sr, Table 1) to confirm that solid state chemistry plays a major part in controlling the composition of seawater.

Although they have similar electronegativities there are some striking differences between the behaviour of the lanthanides and the lithium group in the world oceans (Table 1). In the log K_Y(sw) versus Q_{YO} plot (Fig. 2, ref. 1) the partition coefficients for the lanthanides are among the lowest observed and lie at the end of the main sequence established by 60 elements. The partition coefficients for the lithium group lie on a separate correlation well above the main sequence and they have K_Y(sw) values some five orders of magnitude higher than lanthanides with a corresponding electronegativity (Table 1). Furthermore the lithium group elements have long oceanic residence times and can be described as 'enriched elements'[6] as they are concentrated in the oceans relative to the world rivers (relative oceanic enrichment $RE > 0$, Table 1). The lanthanides, however, are 'depleted elements'[6] ($RE < 0$, Table 1) as they have short residence times in seawater and are effectively removed from solution on entering the world oceans. The scavenging of the lanthanides is very efficient as the concentrations of these elements in seawater are among the lowest observed for the stable elements. This is not primarily attributable to low crustal abundance since, for example, lanthanum, cerium and neodymium are more abundant than tungsten, cobalt and molybdenum in the Earth's crust[10] although the latter elements are respectively two, three and five orders of magnitude more abundant in the oceans[11].

The reason for the effective removal of the lanthanides from the oceans is not to be found in their solution chemistry. Although the lanthanides in seawater are complexed a little more strongly than the lithium group, particularly by carbonate ions (Table 1), a substantial proportion of each element is present as the free ion so that both groups of elements behave as typical (a)-cations[12] with low to intermediate polarising power[7] ($z^2/r < 11$, Table 1). The effective complexing of the lanthanides should favour higher concentrations of these elements in seawater than in river water. Solubility products do not suggest a suitable mechanism for the efficient removal of the lanthanides from seawater. Indeed, while the concentrations of some of the lithium group elements (such as Ca) are limited in seawater by the precipitation of insoluble salts, the lanthanides are several orders of magnitude below the concentration limits set by their insoluble salts (Table 2). For an explanation, therefore, we consider the differences in solid state chemistry between the two groups of elements. A key point here is the concept of 'capture' introduced by Goldschmidt[14] to describe the situation in which the incorporation of a subordinate element into a mineral lattice in place of the dominant rock-forming elements results in a significant stabilisation of the curounding crystal structure. Ion capture results when a site occupant is replaced by an ion with higher polarising power[7] (z^2/r) and/or one which can accommodate a higher coordination number. The capture of lanthanide ions by calcitic minerals is common[10,14] because the lanthanides have a higher polarising power than the alkaline earth cations of similar electronegativity (Table 1) and can accommodate higher coordination numbers[15]. Although Goldschmidt[14] originally introduced the concept of capture in discussing the formation of igneous rocks it is possible that the same process will be apparent in marine diagenesis with the adsorption of the ion onto the mineral surface being followed by ion capture. This process will

# Seawater concentrations from Brewer[11], corrected for complexation of the lanthanide cations (Table 1).

be particularly effective in removing the lanthanides from solution where new minerals are produced in the oceans either by reverse weathering[16] or by biological processes. There is, in fact, abundant evidence for the enrichment of the lanthanides in a range of authigenic minerals including glauconites, phosphorites, foraminiferal tests and manganese nodules[10,17–20]. It is likely that the oceans are depleted in the lanthanide elements relative to the world's rivers because these effects only become apparent when the elements are held in a reservoir with a long retention time (several thousand years at least, Table 1). Evidence for the progressive incorporation of the lanthanides into phosphorites on ageing[21] supports this hypothesis.

The suggestion that ion capture controls the chemistry of the lanthanides in seawater is supported by the differences in behaviour noted between the lanthanides themselves. In comparison with chondritic (non-ferrous meteoric) minerals the lighter lanthanides (the 'cerium earths' La–Eu) are enriched in preference to the heavier lanthanides (the 'yttrium earths', Gd–Lu and Y) in most hydrogenous minerals[10]. This preferential enrichment probably arises because the effect of the increasing polarising power of the cation (z^2/r, Table 1) on going from La to Lu is outweighed by the higher coordination number which the larger, lighter cations are able to accommodate in oxide lattices[15], thus favouring their capture. As a result of their preferential enrichment in mineral structures the 'cerium earths' have significantly shorter residence times ($\bar{t}_Y$) in the oceans and lower partition coefficients (K_Y(sw)) than the 'yttrium earths' (Table 1). The plot of K_Y(sw) against Q_{YO} (Fig. 2, ref. 1) shows that these differences are adequately represented by the electronegativity function, Q_{YO}.

Thus, the chemistry of the lanthanides supports our original deduction[1], based on the distribution of the elements along the K_Y(sw) versus Q_{YO} plot, that the overall composition of seawater is controlled by the solid-state chemistry of the elements. The comparison between the lanthanides and the lithium group also clarifies the mechanism by which solid-state control is achieved in the case of the electropositive elements.

Iron–nickel superstructure in metal particles of chondrites

J. Danon, R. B. Scorzelli & I. Souza Azevedo

Centro Brasileiro de Pesquisas Físicas, Av. Wenceslau Braz, 71-Rio de Janeiro, Brasil

M. Christophe-Michel-Lévy

Laboratoire de Minéralogie-Cristallographie, associé au CNRS-Université Paris VI, France

Ordered solid solutions (superstructures or superlattices), in which atoms of one kind segregate into a particular set of lattice positions, are usually obtained by slow cooling at the critical ordering temperature. However, the equiatomic Fe–Ni ordered phase (superstructure Llo) has been obtained only by radiation-induced ordering[1], since the diffusion rates of the metallic atoms are very slow at the ordering temperature T_c = 320 °C (ref. 2). The Fe–Ni ordered phase has recently been detected by Mössbauer spectroscopy and X-ray diffraction in the taenite of the iron meteories Cape York (III A), Toluca (I)[3] and reported as a major constituent of the Ni rich ataxite (35% Ni) Santa Catharina[4]. We report here Mössbauer spectra, scanning electron microscopy and X-ray measurements, which show that the metal particles of the chondrites Saint-Séverin (LL6), Lake Labyrinth (LL6) and Parambú (polymitic LL breccia) contain large proportions of this Fe–Ni superstructure and that the phase is present in different amounts in the chondrites L'Aigle (L6), Peetz (L6), Shaw (L6), Bjürbole (L4) and Allegan (H5).

The identification of the Llo superstructure in Fe–Ni alloys by Mössbauer spectroscopy is based on the fact that the ordered phase exhibits an asymmetric 6-line spectrum due to a quadrupole splitting arising from the non-cubic environment of the Fe atoms in this structure. Detection by X-ray diffraction is more difficult due to the very weak intensity of the superstructure lines[5].

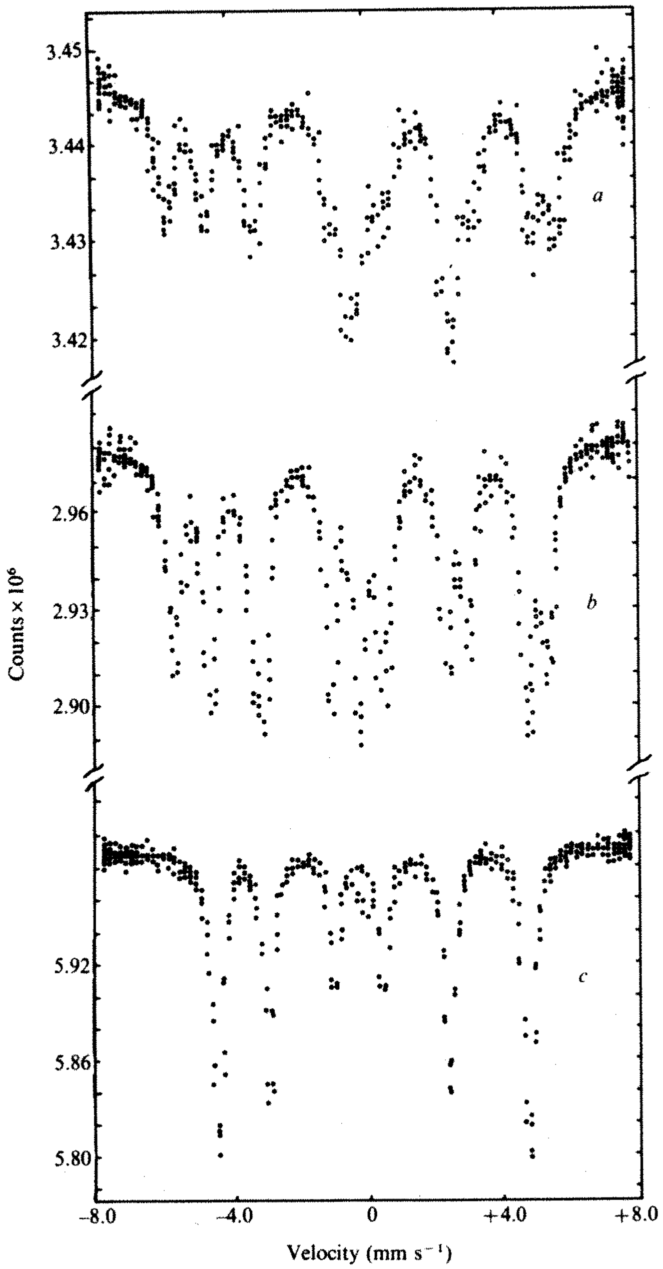

Fig. 1 Mössbauer spectra of St Séverin metal fraction at room temperature recorded with a sinusoidal drive and HP multichannel analyser (1,024 channels). The data were fitted with a 370/145 IBM computer. *a*, Untreated metal fraction magnetically separated and sieved to 40–80 μm. *b*, Metal fraction (80–150 μm) after HF treatment. *c*, Ordered phase in pure form extracted from metal fraction. The quadrupole effect is seen in the asymetric position of the outer lines. From spectrum *c* one identifies the lines corresponding to the ordered phase in the upper spectra *b* and *a*.

Chondrites exhibit complex Mössbauer spectra[6] which arise from the superposition of: (1) quadrupole interaction from the paramagnetic iron silicates which yields two pairs of doublets. (2) Magnetic hyperfine interaction from the α-phase (kamacite) or the α_2-phase (martensite), γ-phase (taenite) and troilite, which yields three six-line spectra resulting in a total of 18 partially overlapping lines. (3) A single central line arising from paramagnetic γ-phase (taenite).

With magnetically enriched samples relatively large amounts of silicates and troilite still remain attached to the metallic phase. Only in a favourable case such as St Séverin, which contains a large proportion of the ordered phase, was it possible to detect the superstructure by Mössbauer spectroscopy without further purification of the sample (Fig. 1*a*).

We found that a separation of the metals from the silicates (up to about ~95%) and the troilite can be achieved by boiling the metallic fraction in concentrated HF (40%) for a few minutes and submitting the residue to a magnetic separation. This treatment does not affect the metallic phase, as we observed in experiments with several Ni-rich Fe-Ni alloys. Moreover the Ni/Fe ratios estimated from the areas corresponding to the several metallic phases observed in the Mössbauer spectra (Fig. 1*b*) are in reasonable agreement with those reported by chemical analysis.

Table 1 lists the hyperfine parameters derived from the Mössbauer spectra of the chondrite metals in which the ordered phase has been observed, as well as the proportions of the Fe–Ni alloy phases in these meteorites.

The relatively large Ni/Fe ratio found in the metallic phase of the LL chondrites favours the formation of the Llo superstructure which also seems to be common in the L chondrites, although in smaller proportions. The presence of the ordered phase in the H chondrite Allegan was confirmed by a Debye–Scherrer diagram (filtered CoKα) of an untreated metal particle presenting a cloudy taenite border which showed the α-phase, the γ-phase and (100), (110) and (210) superstructure lines (J. Laugier, personal communication).

Within the sensitivity of the Mössbauer technique (up to a few per cent) no evidence for the ordered phase was found in the

metal phases of the H chondrites Nadiabondi, Menow, Ipiranga, Marilia, São José do Rio Preto, Avanhandava and Estacado. The X ray of a Nadiabondi metal grain, however, exhibited a faint (100) superstructure line.

We were able to isolate the Fe–Ni ordered alloy as a single phase constituent. In a Cu^{2+} solution both Fe(0) and Ni(0) metals are dissolved[7] but the rate of dissolution is slower for the ordered phase. A fraction in which this phase is enriched can be obtained by treating the metallic fraction (after HF) for several minutes in a $CuCl_2/2KCl$ solution. Cu(0) is next eliminated from the metal residue with concentrated ammonia. A sample extracted from St Séverin exhibits a Mössbauer spectrum which corresponds to an essentially pure ordered phase (Fig. 1*c*). The composition of the alloy in this sample was found to be Fe(60%) and Ni(40%), in the domain of stability of the Llo superstructure[2].

Scanning electron microscopy showed an assembly of small structures (Fig. 2), similar to those reported by Scott in crystallographic studies of cloudy taenite[8], with sizes between 1,500 and 3,000 Å and quite homogeneous metal composition.

The parameter $a_0 = 3.579 \pm 0.001$ Å obtained by X-ray diffraction of this sample is that reported for the ordered phase[9,10] and is smaller than that corresponding to the disordered alloy $a_0 = 3.596 \pm 0.001$ Å. With a CoKα radiation in a 24-h exposure the (100), (110), (210), (211) and (221) weak superstructure lines were detected in the Debye–Scherrer diagram[11].

The value of the quadrupole splitting of the ordered phase extracted from Parambú ($+0.12 \pm 0.01$ mm s^{-1}) is significantly smaller than that observed with St Séverin ($+0.21 \pm 0.01$ mm s^{-1}). Parambú is a polymitic breccia with evidence of a shock event[12] whereas St Séverin presents little evidence of shock. This suggests that the shock event, either from pressure effects[13] or by impact heating, tends to disorder the Fe–Ni superstructure ($T_c = 320$ °C), as indicated by the decrease in the value of the quadrupole splitting[14]. This would explain the low value ($\Delta E_Q = +0.13 \pm 0.05$ mm s^{-1}) observed with Lake Labyrinth, which according to Taylor and Heymann[15] is a heavily shocked chondrite (class C(H)).

The cases of Peetz and Shaw are particularly interesting since their Mössbauer spectra corresponds to the α (or α_2) phase, as in the other chondrites, and a ferromagnetic γ phase with same hyperfine parameters of the superstructure but largely disordered ($\Delta E_Q \sim 0$). The metallic phases in Peetz indicated evidence of shock, but only moderate reheating[15]. The relatively large negative value of the ^{57}Fe isomer shift observed with Peetz is compatible with a pressure effect above 200 kbar[16].

Recent studies indicate that Shaw is a complex meteorite which experienced an unusual event, superimposed on a normal slow cooling history, probably connected with an intense shock[17–20]. The destruction of the superstructure in Shaw could arise by impact reheating of the meteorite to temperatures above 320 °C and rapid cooling to lower temperatures which prevented the subsequent ordering of the Fe–Ni alloy.

We thank J. M. Knudsen for his continued interest, J. Laugier, K. Imakuma and H. A. Abdel-Rehim for X ray measurements, and C. Vilbert for scanning electron microscope measurements. Metal fraction of chondrites were supplied by P. Pellas and Brazilian chondrite samples by C. B. Gomes.

Ionospheric–magnetospheric contributions to storm-time magnetic field changes near dip equator

C. A. Reddy, V. V. Somayajulu & K. S. Viswanathan

Space Physics Division, Vikram Sarabhai Space Centre, Trivandrum 695 022, India

Experimental identification of the electric current systems in the ionosphere and magnetosphere during magnetic storms is a fundamental problem. We report here a new approach to resolving the relative contributions of ionospheric and magnetospheric currents to the storm-time geomagnetic field variations at equatorial latitudes. In this approach, the VHF backscatter radar-measured electric field changes in the equatorial electrojet and the simultaneous surface magnetic field changes are analysed to determine quantitatively the ionospheric contribution ΔF_I to the storm-time geomagnetic field perturbation ΔF_D. The magnetospheric contribution ΔF_M is then determined from:

$$\Delta F_D = \Delta F_I + \Delta F_M \qquad (1)$$

This method has yielded extremely interesting results for the magnetic storm of 15 February 1978. It has a great potential for providing valuable new insights into the nature and time evolution of the complex storm-time current systems in the ionosphere and magnetosphere.

0028–0836/79/410471—04$01.00

A coherent VHF backscatter radar and a proton precession magnetometer (PPM) were used for storm-time observations at Thumba near Trivandrum (dip 56′ S; lat, 8.5° N; long, 77° E). The two experimental systems are described elsewhere[1,2]. Later improvements have enabled us to record the radar digital data on a magnetic tape and process it on an IBM 360/44 computer. The data recorded at 1-min intervals are used here. As the dip angle is very small (56′ S) the approximation $\Delta H \simeq \Delta F$ is used, where ΔH is the perturbation in the horizontal component of the magnetic field. All interpretations given here are based on this approximation. For the radar geometry at Thumba, the mean Doppler frequency $\bar{f}_D$ is negative when the drift of the ionisation irregularities (and electrons) is westward under the action of an eastward electric field. From the observed $\bar{f}_D$ fluctuations, the fluctuations of the electron drift velocity (which are directly proportional to electric field fluctuations) can be determined from standard theoretical relationships[3].

Figure 1 shows the observed variations with time of the geomagnetic field perturbation ΔF, the backscatter signal strength V and the mean Doppler frequency $\bar{f}_D$ of the radar signals on 15 February 1978. A sudden commencement storm started at 03.17 IST (82.5° EMT). The most remarkable features in Fig. 1 are: (1) a delay of about 1.5 h in the first appearance of the radar signal (at 0905 h) indicates that the normal eastward electric field is suppressed between 0730 and 0900 h; (2) the large in-step fluctuations of ΔF, $\bar{f}_D$ and V between 0905 and 1430 h of the storm initial phase; (3) a large main phase decrease of ΔF to negative values between 1530 and 1630 h, even while $\bar{f}_D$ is increasing shows that a magnetospheric current is responsible for the large negative value of ΔF; (4) a repeated disappearance of the radar signal for durations of 20–30 min, indicating the reversals of normal daytime eastward electric field in the electrojet; (5) the disappearance of large amplitude fluctuations at about 1800 h after the storm recovery phase has set in. Other interesting details of the observations shown in Fig. 1 will be discussed later. The time variations of ΔF, $\bar{f}_D$ and V on 16 February 1978 were also recorded during the recovery phase of the storm.

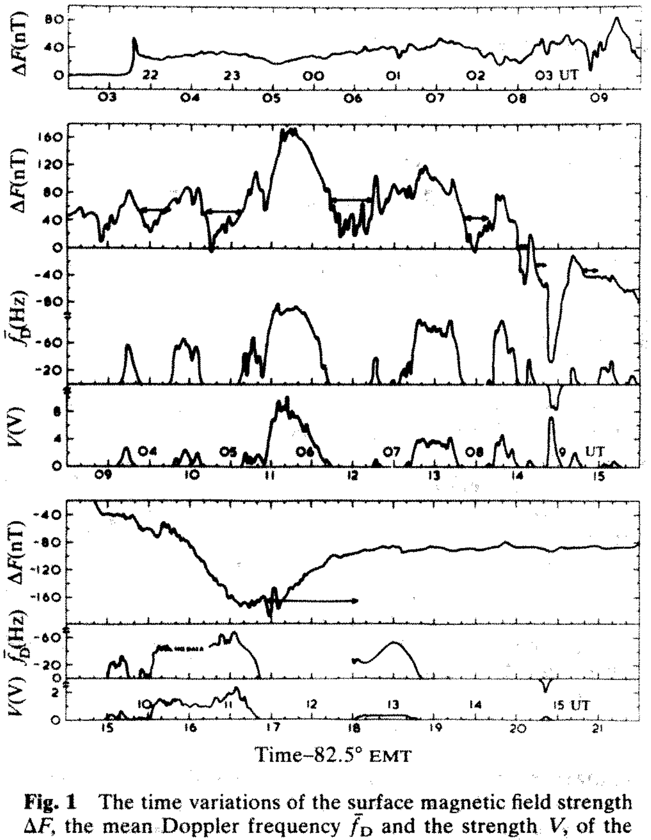

Fig. 1 The time variations of the surface magnetic field strength ΔF, the mean Doppler frequency $\bar{f}_D$ and the strength V, of the VHF backscatter radar signals on 15 February 1978. The horizontal arrows (↔) mark the periods during which the radar signals disappeared. $A_p = 48$. Time is 82.5° EMT.

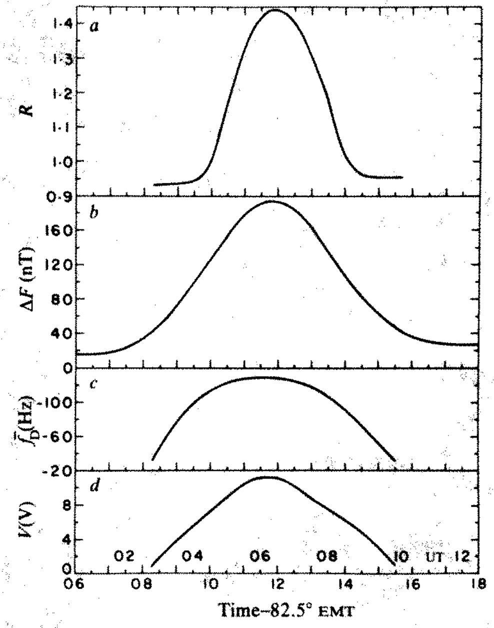

Fig. 2 The time variations of ΔF, $\bar{f}_D$ and V on 11 February 1978 (a quiet day with $A_p = 5$). $R = \Delta F/\bar{f}_D$ is also shown (a).

The interesting and informative experimental observations shown in Fig. 1, along with similar observations on a quiet day, have been used to quantify the ionospheric and magnetospheric contributions to the storm-time surface magnetic field perturbations at Thumba. Figure 2 shows the time variations of ΔF, $\bar{f}_D$ and V on 11 February 1978 which is a quiet day with $A_p = 5$. In Fig. 2a, the ratio $\Delta F/\bar{f}_D$ is shown as R,

$$R = \Delta F/\bar{f}_D \quad (\mathrm{nT})\,(\mathrm{Hz})^{-1} \tag{2}$$

Using the suffixes Q and D respectively for quiet and disturbed day values, the approximation $\Delta F_Q = \Delta F_I$ has been used instead of $(\Delta F_I)_Q = (\Delta F - D_{st})_Q$. A later check on 11 February D_{st} values shows that R value may be in error by 10–20% due to the non-subtraction of D_{st} values. Note that

$$\Delta F_I = k_1 \Sigma_3 E_y \quad \text{and} \quad \bar{f}_D = k_2 \bar{\mu} E_y \tag{3}$$

Here, $\bar{\mu}$ is a mobility parameter involving the collision and gyro frequencies of ions and electrons; k_1 and k_2 are constants of proportionality which are independent of the medium; E_y is the east–west electric field which varies very little with height if it is a global scale field and is assumed to be height-independent; Σ_3 is the height-integrated Cowling conductivity; and the bar denotes a weighted average over that height region which contributes to the backscatter signal. From equations (2) and (3), we can write

$$R = (k_1/k_2)\Sigma_3/\bar{\mu} \tag{4}$$

Thus, the variation of R should represent the variation of Σ_3, since k_1 and k_2 are constants and $\bar{\mu}$ is likely to have negligible variation with time of the day compared with that of Σ_3.

If it is assumed that at any given local time the change in Σ_3 from a quiet day to a disturbed day is much smaller than that in the electrojet electric field, then ΔF_I on a disturbed day can be deduced from

$$\Delta F_I = R_Q(\bar{f}_D)_D \tag{5}$$

Then the magnetospheric contribution ΔF_M is determined from equation (1). Obviously, the errors in ΔF_I and ΔF_M deduced in this way are proportional to the difference $(R_D - R_Q)$. The fractional change in R from quiet to disturbed day is not likely to exceed 15–20% most of the time while the ΔF_I and ΔF_M changes from quiet to storm day are in the range of 50–200%. Pending a further quantitative study of the $(R_D - R_Q)$ values, we assume that R_Q values can be used on a disturbed day to determine storm time ΔF_I and ΔF_M. Ideally, we need at least 4 or 5 quiet days' observations to arrive at the quiet day mean value of R for a given month. The induced Earth current effects are not separated out in the present analysis.

The ionospheric and magnetospheric contributions to the surface magnetic field perturbations during the 15 February storm have been estimated using the method outlined above. The results are shown in Fig. 3, where the chain curve represents the quiet day variation of ΔF and the dotted portions of the ΔF_M curve correspond to the times of disappearance of backscatter signals. If the eastward current and hence ΔF_I is assumed to be zero at such times, then $\Delta F_M = \Delta F_D$ at such times and this is the lower limit to ΔF_M. On the other hand, the broken portions of the ΔF_I and ΔF_M curves correspond to those times at which backscatter signals on the disturbed day are available but not on the quiet day, and hence an extrapolated value of R has been used. R is assumed to have its asymptotic value of 0.96 at such times.

The ΔF_I behaviour between 0900 and 1500 h indicates that the electrojet electric field and current are fluctuating violently during this time, with the average levels being rather low compared with quiet day values. The time variation of ΔF_I between 1500 and 1900 h shows that there is an enhancement of the eastward electric field and current values over the quiet day (11 February) levels in this time sector.

Consider the behaviour of ΔF_M. The circles in Fig. 3 represent the smoothed values of ΔF_M obtained through a 60-min running average of 1-min values. Between 0900 and 1400 h, ΔF_M is essentially positive and is subject to strong oscillations of 4–6 min period and to longer period (20–40 min) perturbations like ΔF_I. The 4–6 min oscillations are apparently hydromagnetic waves originating in the magnetosphere and propagating to the equatorial ionosphere[4]. In fact, detailed examination has shown that the short period oscillations as well as the longer period bay type perturbations in ΔF_I and ΔF_M are in antiphase with each other. Such simultaneous phase-coherent perturbations in ΔF_I and ΔF_M indicate that the magnetosphere, auroral ionosphere and equatorial ionosphere together respond as a single electrodynamic system to storm-time disturbance forces; and the interactions and feedback effects within this system cannot be ignored in any study of the physical processes. This and other features, when studied in detail, may provide important clues to the nature of magnetosphere–ionosphere responses and interactions during storms and substorms.

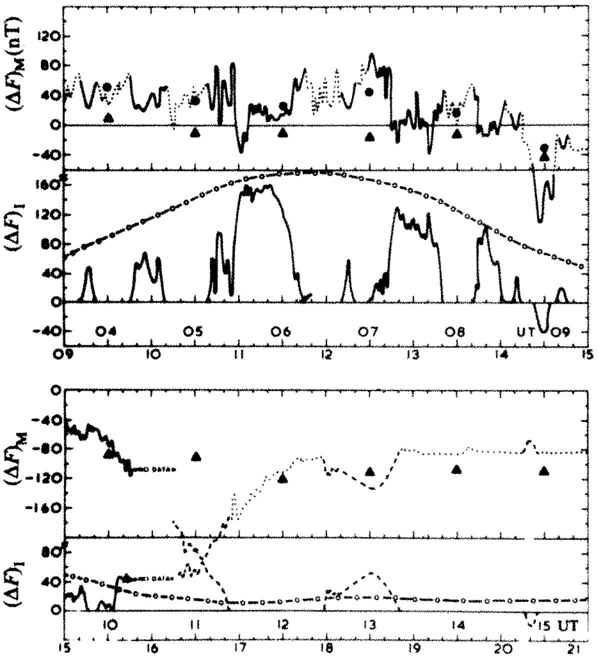

Fig. 3 The time variations of ΔF_I and ΔF_M on 15 February 1978. Solid line, ΔF_D; O—O, ΔF_Q; ▲, D_{st}. $A_p = 48$.

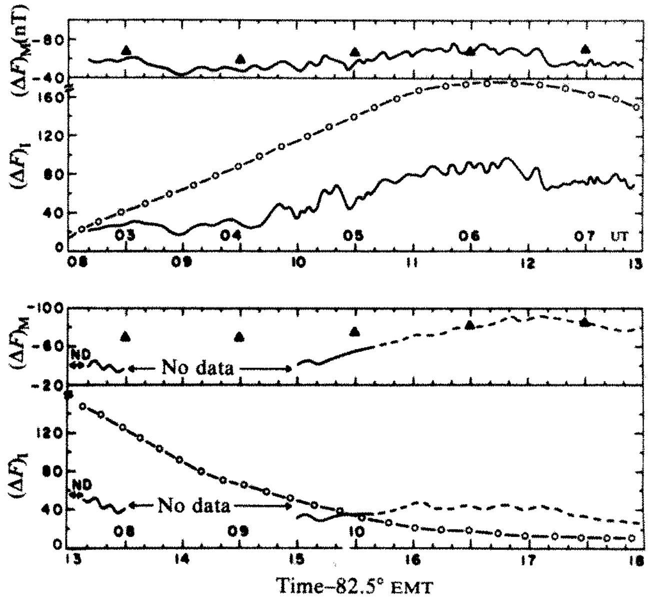

Fig. 4 The time variations of ΔF_I and ΔF_M on 16 February 1978. Solid line, ΔF_D; O—O, ΔF_Q; ▲, D_{st}. $A_p = 11$.

Moreover, the agreement between the D_{st} values and ΔF_M values is not good between 0900 and 1430 h. Apparently, the D_{st} analysis cannot correctly bring out the magnetospheric contribution to ΔF during this initial phase which is dominated by short-period oscillations and irregular perturbations.

The magnetospheric contribution ΔF_M begins to attain large negative values rather rapidly from 1520 h onwards. Significantly, the short-period oscillations and bay-type disturbances come to an abrupt stop during this phase of the storm. However, the large rapid decrease of ΔF_M and its recovery between 1600 and 1730 h are not shown up by the D_{st} analysis. But, the D_{st} values and ΔF_M values show a remarkable agreement after 1730 h. Obviously, during the late afternoon–evening sector, the surface magnetic field perturbation is caused predominantly by magnetospheric currents; and ΔF_M continues to be large throughout the night of 15 February.

Similar analysis has been done for 16 February, and the main results (shown in Fig. 4) for the recovery phase are: (1) During the recovery phase of the storm ΔF_I is still well below the quiet day value until 1400–1500 h IST; but ΔF_I clearly exceeds (by a factor of 2 or 3) the quiet day value between 1600 and 1800 h. These features indicate that a disturbance associated westward electric field persists in the equatorial electrojet during the recovery phase in the morning–noontime sector, followed by an enhanced eastward electric field in the late afternoon–evening sector. (2) On 16 February there is an excellent agreement in general between D_{st} and ΔF_M values (which are high), implying that once the symmetric ring current is well developed as a dominant feature of the magnetosphere, the procedure used for deducing the D_{st} values is able to reproduce its behaviour quite well.

The present method opens up new possibilities in quantitative studies on the equatorial electrojet current changes during different phases of magnetic storms. However, the quantitative accuracy of the present method can be improved only through further refinements in the methods of radar measurement and the data analysis. For example, the variation of R in Fig. 2 has a gross resemblance to the expected variation of Σ_3 but it shows important deviations as well. The causes of the deviations are being investigated. Similarly, we are aware[5] that local winds with vertical shear can modify and distort the height structure of the electrojet, but the wind-generated electric fields are usually much weaker than the large storm-time electric field changes. On the other hand, the excellent agreement between ΔF_M and D_{st} values over long periods of storm-time (particularly after the development of the ring current) cannot be fortuitous, and this lends support to the assumption that change in the R value from quiet to storm day is small compared to the changes in E_y. In any case the estimated errors in ΔF_I and ΔF_M can be as large as 25% in the first attempt, although we believe that the errors are much less for a considerable period of the storm-time.

Do sponges help hold coral reefs together?

Janie L. Wulff & Leo W. Buss

Evolutionary Biology Group, Department of Biology, OML Yale University, New Haven, Connecticut 06520

The growth and form of coral reefs is the result of a complex balance between rates of carbonate accretion and carbonate loss. Reef organisms have traditionally been classified, with respect to their role in this balance, as primary frame-builders, frame-cementers, biological eroders or sediment producers[1,2]. Scleractinian corals are the primary frame-building organisms in most modern reef environments. The growth of many such corals generates large volumes of unoccupied cryptic space. Successful reef construction occurs if this space is infilled with sediment, this sediment is cemented by frame-cementing organisms, and the resulting complex is subsequently lithified[3–5]. As this lithification process may be slow, frame material is highly susceptible to becoming separated from the reef framework due to the action of physical disturbance (such as wave shock) before permanent consolidation[6–10]. We present here experimental evidence that demosponges (which may be second only to scleractinian corals in space occupancy on many Caribbean reefs) play an important role as interim binders of unconsolidated frame material, a process which is expected to increase rates of carbonate accretion.

Although sponges may bind carbonate to the reef frame in several reef zones (for example, interstices of ramose corals and carbonate rubble), our investigations have focused on Caribbean deep fore-reef environments. Deep fore-reef zones are characterised by steeply sloping sand plains dotted with small patch reefs or larger reef pinnacles and are bounded to the seaward by vertical rock walls which drop to considerable depths. Scleractinian corals growing in this zone generally exhibit a foliaceous growth morphology. Such forms are especially susceptible to disengagement from the reef since their attachment zones are small; their undersurfaces are largely devoid of live coral tissue, leaving them open to recruitment of boring organisms; and they extend off the reef rather than resting on it, making them unstable once their attachment zone is weakened[11]. Foliaceous corals have become separated from the reef frame by the forces exerted by a feeding parrotfish, by the actions of storm-induced wave shock[6–10], by the fins of a careless scuba diver, or simply due to collapse under their own weight[11]. Once separated from the reef, corals cannot reattach and are rarely consolidated.

Non-burrowing sponges characteristic of deep fore-reef environments are of two general types: those which inhabit the holes and crevices in the reef frame and those which inhabit exposed reef substrata. Cryptic sponges (such as *Agelas clathrodes* (Schmidt)) commonly have zones of attachment which include both the undersurface of foliaceous corals and the reef frame itself. The porosity of the reef frame may cause many of these sponges to extend from one attachment spot on the undersurface of a coral, through the reef frame to an attachment zone on another coral.

Sponges, including those which inhabit open reef substrata, have been observed to attach to one another without harm to either side[12,13]. Experiments performed on the barrier reef of Belize show that several such sponges may also kill small patches of coral tissue on contact and bind to the exposed coral skeleton. Growing tips of at least five individuals of each of 12 sponge species were severed with a diving knife and attached to living agariciid corals with cotton twine. As controls, pieces of commercial bath sponge were attached to living corals. The contacts were examined after one week for evidence of coral tissue death and sponge–coral binding. Of the 12 species, 10 killed a small patch of coral tissue and bound to the skeleton (Table 1). The two remaining species killed small patches of coral. The bath sponge had no observable effect. The morphological flexibility of sponges, their ability to attach to other living sponges and corals, and their ability to attach to clean substrata with any part of their colony results in the formation of anastomosing networks of several sponge species which have many attachment points on different coral colonies and the reef frame.

Corals, although far more constrained in morphological flexibility by their rigid skeletons, can also modify their forms in the presence of certain sponges. We have observed colonies of *Agaricia agaricities* (Linn.), *Agaricia lamarcki* (E & H), and *Helioserius cucullata* (E & S) which have encircled the tissue and even attachment zones of nearby sponges with skeletal material. These observations may simply reflect a passive response of the coral to any obstruction within the path of growth.

Table 1 Sponge–coral binding experiment

Sponge species	Total no. of individuals tested	Total no. killing tissue	Total no. binding to coral
Agelas clathrodes (Schmidt)	5	5	0
Agelas conifera (Schmidt)	5	5	5
Agelas sceptrum (Lam.)	5	5	5
Aplysina cauliformis (Carter)	5	5	5
Callyspongia sp.	7	7	7
Ectyoplasia ferox (D & M)	10	8	8
Haliclona rubens (Palles)	30	25	15
Iotrochota birotulata (Higgin)	5	5	5
Niphates erecta D & M	10	5	0
Smenospongia aurea (Hyatt)	5	3	3
Thalysias juniperina (Lam.)	5	2	2
Unidentified	7	7	5
Control	5	0	0

Experiments were performed while operating from the RV Alpha Helix. Two locations, one each in the lee of Glovers and Lighthouse Atolls at depths of 20–30 m, were studied. The Lighthouse Atoll site is 1 mile south of Long Cay and the Glovers site on the reef pinnacle, Movie Mountain, located on the southwestern extreme of the atoll. The experiment does assist with the understanding of the mechanism (for example, allelopathy and abrasion) by which sponges kill coral tissue. As these results represent the number of individuals binding to corals in only 1 week, they probably underestimate the actual capacity of these sponges to bind to corals.

0028–0836/79/410474—02$01.00

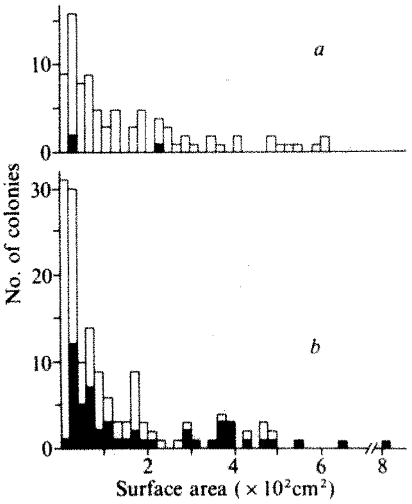

Fig. 1 Size against frequency distribution of foliaceous corals originally extant on *a*, unmanipulated reefs and on *b*, manipulated reefs. Shaded histograms represent those corals which became separated from the reefs. Patch reefs selected were comparable in size and sponge–coral faunal development. Specific data on patch morphology, sponge–coral distributions, and sponge–coral identifications are available from the authors. Coral surface area measurements were made by approximation to regular polyhedrons. Corals which immediately fell off the manipulated reefs when sponges were removed constituted <2% of the total corals manipulated (and are not included in the analysis) indicating that any disturbance to the reefs involved in removal of sponges was minimal. Data presented are clumped for all patches over the two observation periods. There was negligible sponge regrowth on manipulated reefs over the experimental period.

The hypothesis that sponges bind corals to the reef frame has previously been considered[14–17]: for example, Goreau and Hartman stated that "large encrusting sponges often support and hold such corals in place long after their original holdfasts have been eroded away". To test this hypothesis we removed sponges from patch reefs on the fore-reef slope of Marsagantupo Island, San Blas, Panama, and monitored how the coral survived. The experiments were performed on the leeward side of the island at depths ranging from 13 to 20 m. Marsagantupo Island is exposed directly to the Caribbean Sea. The first 3 months of the experimental period correspond to the dry season in Panama, the period of greatest swell. Although physical data are scant for this region, the Caribbean coast of Panama is regularly exposed to seas up to 10 ft (ref. 18). Eight small patch reefs were selected and all corals mapped as to their position on the patch. All sponges, with the exception of borers and surface encrusters of <1 cm vertical relief, were carefully removed by hand or with a diving knife from half of the reefs. The patches were revisited at three and six months after the removal and all corals remapped.

Figure 1*a* shows the size (surface area live tissue) frequency distribution of foliaceous corals originally extant on unmanipulated reefs and Fig. 1*b* shows that for manipulated reefs. Control reefs lost 2% of their colonies (2% surface area) within three months and 4% of their colonies (3% surface area) after six months; whereas manipulated reefs lost 26% of their colonies (29% surface area) within the first three months and a total of 40% of their colonies (46% surface area) after six months. The high mortality of small colonies, many of which had no direct contact with any sponge, reflects the need of juvenile corals for stable substrata on which to grow. Those small corals which have been asexually reproduced (or which have settled) on top of larger colonies are clearly as dependent on sponge binding as their older counterparts.

The traditional interpretation of the role of sponges in the reef carbonate balance has emphasised the destructive influence of a small group of biological eroders. Although the influence of biological erosion or the binding capacities of other reef sponges should not be underestimated. Demosponges clearly should be taken into account in the reef carbonate balance equation.

This research was supported by NSF grant OCE 76-23364. Shiptime was provided by the RV Alpha Helix Program and the Smithsonian Tropical Research Institute. K. Rützler provided sponge identifications. We thank L. Fischelson, J. B. C. Jackson, G. Vermeij and C. M. Wahle for their support.

Bryozoan overgrowth interactions—the interdependence of competition for space and food

Leo W. Buss

Evolutionary Biology Group, Department of Biology, OML,
Yale University, New Haven, Connecticut 06520

Space has been demonstrated repeatedly to be a limiting resource to sessile suspension-feeding invertebrates[1–7,15], whereas the question of whether food resources are ever limiting has long been a controversial topic[8,9]. On the basis of previous research and in the virtual absence of any mechanistic understanding, it is commonly assumed that interactions can be interpreted as competition for spatial resources alone. This assumption is clearly unacceptable. Whereas a mobile organism might feed in one location rich in prey, spawn in another safe from predators of its young, and hide in yet another inaccessible to its own predator, a sessile organism cannot separate, spatially or temporally, its demands for food to eat and space on which to live. For the sessile organism, access to food implies access to space and vice versa. Consequently, the empirical observation of competition for space does not justify the assumption that competition for food is unimportant. I report here that competition for food among suspension feeders can occur and may, in fact, provide a mechanism by which sessile organisms compete for space.

Competition between colonial, encrusting organisms occurs whenever the space available on a particular hard substratum is reduced sufficiently for the lateral margins of colonies to come into contact[10]. These organisms grow[11,12] and interact[1,13–19] along their colony margins exclusively and competition is commonly characterised by overgrowth (Fig. 1*a*). The physical overgrowth of one organism by another is commonly irreversible, resulting in the death of the overgrown tissues[1,13–19]. In that the overgrowing organism now occupies the space which the overgrown organism had occupied previously, such interactions constitute competition for space[20]. Although little is known of the mechanisms of overgrowth, they must involve differential growth along interspecific colony margins. The organism that grows fastest here will overgrow its competitor, perhaps by

0028-0836/79/410475—03$01.00

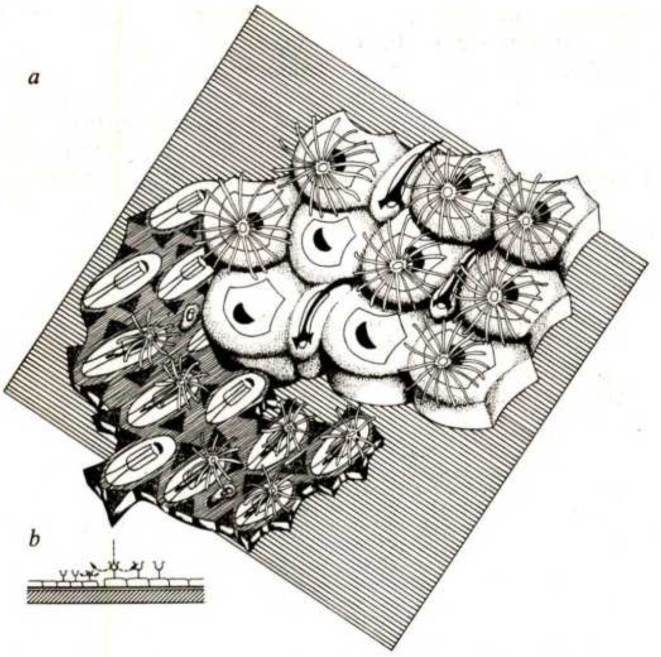

Fig. 1 The overgrowth phenomenon. *a*, Frontal view. In the upper portion *O. alula* has overgrown *A. tincta*, whereas in the lower portion the colony which is growing fastest here will overgrow, that is, that colony which first produces a zooid here. *b*, side view, showing currents and interference effect.

interfering with the access of its competitor to food resources (Fig. 1*a*, *b*).

Onychocella alula (Hastings) and *Antropora tincta* (Hastings) are two encrusting anascan bryozoans which co-occur on intertidal and shallow subtidal cobble in the eastern Pacific of Panama. The feeding organs of individual zooids (lophophores) extend only a few hundred micrometres above the surface of the colony (*O. alula* and *A. tincta*, respectively: 17 and 12 tentacles, 790 and 410 μm tentacular bell diameter, 320 and 280 μm introvert length, 545 and 295 μm tentacle length), within or very close to the layer of stagnant water adjacent to the substratum[21,22]. The dominant characteristics of the flow regime surrounding them are those produced by the feeding activities of the organisms themselves[21,22]. Hence, when in contact, the feeding currents produced by the larger, more robust lophophores of *O. alula* might be expected to interfere with currents produced by adjacent smaller lophophores of *A. tincta* (Fig. 1*b*).

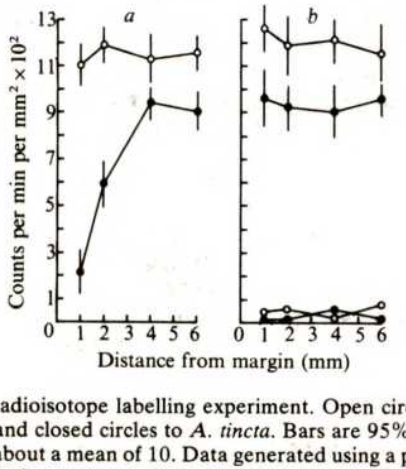

Fig. 2 Radioisotope labelling experiment. Open circles refer to *O. alula* and closed circles to *A. tincta*. Bars are 95% confidence intervals about a mean of 10. Data generated using a piece of lead shaped to the contour of the colonies and impermeable to γ emissions. *a*, Interaction experiment; *b*, bottom lines: rinsing process control; top lines: intracolony effects control.

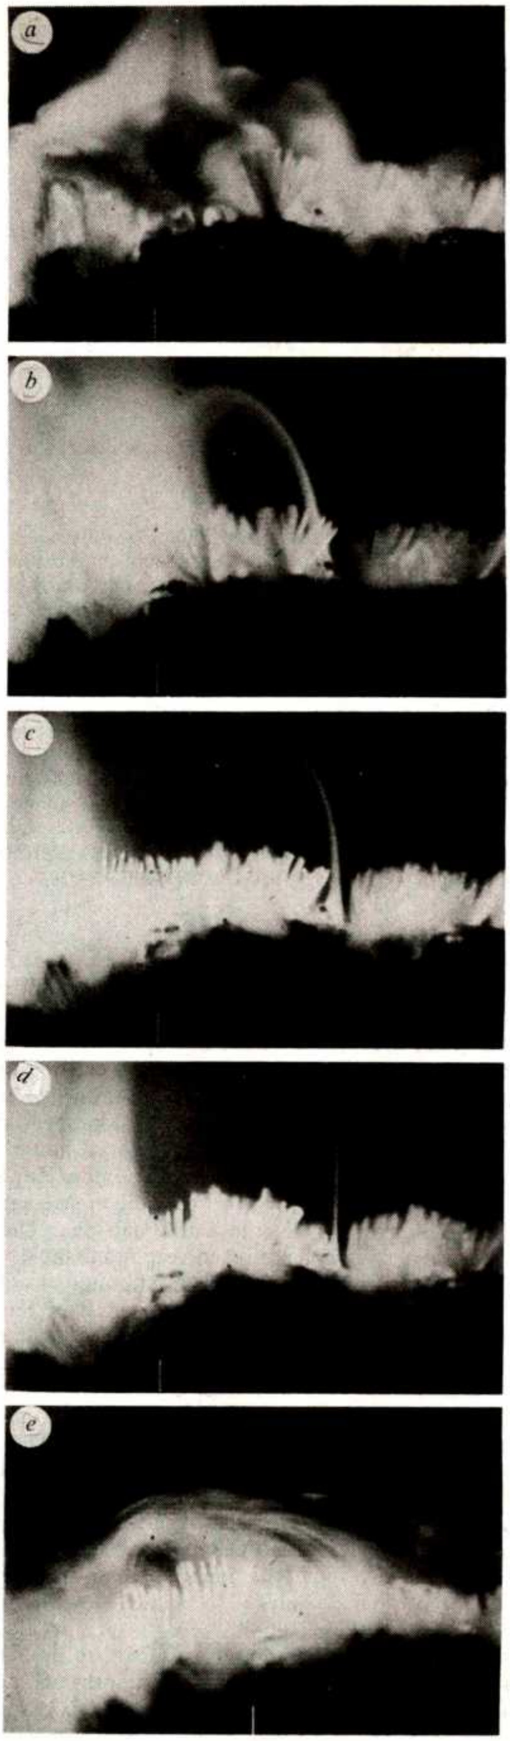

Fig. 3 Microcurrent interference. The point of colony contact is indicated by the bar at the base of all frames. *A. tincta* is the colony to the right of the bar. *a–d*, elapsed time: *a*, 0:00; *b*, 0:19; *c*, 0:45; *d*, 3:32 (min:s). *e*, elapsed time: 0:53. Magnification ≅ ×60. See text for discussion.

To test this hypothesis, competing colonies were allowed to feed on radioactive particles, and feeding efficiency (clearance rate) was calculated as a function of the distance from the interspecific contact. Substrata on which *O. alula* and *A. tincta* were in contact, but on which overgrowth had not yet occurred, were collected at Punta Paitilla, Panama, and maintained in running seawater at the Smithsonian Tropical Research Institute. Colonies were allowed to acclimate and when feeding, 5 ml of human albumin microspheres (3M Corp., size range 5–90 μm, $\bar{x} = 25$ μm, s.d. = ±15 μm, concentration = $5 \pm 2 \times 10^6$) labelled with 5 mCi of ^{99}Tc were introduced into the container. The experiment was aborted if feeding of both colonies was not continuous for the entire 1 h experimental period. Complexities due to possible translocation effects do not occur over this time interval[23]. On termination, colonies were killed, rinsed for 1 h under a high-speed jet of seawater, and counted using facilities at the Gorgas Memorial Hospital, Canal Zone. Results are as hypothesised (Fig. 2*a*); the smaller *A. tincta* showed a significant local reduction in clearance rate in contact with *O. alula*, but *O. alula* showed no such reduction. Two control experiments were also carried out. Dead colonies were allowed to 'feed' on labelled microspheres and only a negligible proportion of these remained adherent to colony surfaces after rinsing (Fig. 2*b*, bottom lines). *O. alula* and *A. tincta* were allowed to feed on labelled microspheres in the absence of one another to control for intracolony effects, but no such effect was detected (Fig. 2*b*, top lines).

The hypothesis that the clearance rate reduction is due to an active interference was confirmed by producing videotapes of interacting colonies. Using a hypodermic syringe, a thin stream of milk–seawater suspension[24] was introduced into an experimental container above the interactive margin. The stream was initially disrupted by feeding activity, forming a broad cone of milk (Fig. 3*a*), which then dispersed to form a cloud above the *O. alula* colony (Fig. 3*b*). Within seconds, the feeding of *O. alula* filtered the water sufficiently for a zone of cleared water, enclosed by the emerging white band (Fig. 3*b*, *c*), to form. This zone expanded and, after several minutes, stabilised over the *A. tincta* colony (Fig. 3*d*), as indicated by the stationary white band. In this region, *A. tincta* had access only to water previously filtered by *O. alula*. The width of this zone measured from the interspecific margin to the stationary band was 3.07 ± 0.24 mm, equivalent to the distance of a clearance rate reduction in the labelling experiment (2–4 mm, see Fig. 2*a*). In an additional experiment (Fig. 3*e*), where milk was added above the *A. tincta* colony, no zone of cleared water was produced. In contrast to the first experiment, the milk streams away from *A. tincta* lophophores to those of *O. alula*. In both cases, *O. alula* interfered with the access of *A. tincta* to food resources, that is, competition for food occurred between these suspension feeders.

To overgrow *A. tincta*, *O. alula* must grow faster than *A. tincta* at the point of colony contact. Unpublished field observations of colonies not in competition have shown that *A. tincta* grows faster than *O. alula*, irrespective of colony size. The observation that *O. alula* interferes with the access of *A. tincta* to food resources and that this interference effectively reduces *A. tincta* food intake suggests that this overgrowth is derived from the mechanism proposed. Competitive interactions for spatial resources may be mediated by competition for food.

Action of a nematode-trapping fungus shows lectin-mediated host–microorganism interaction

Birgit Nordbring-Hertz

Many nematode-trapping fungi capture nematodes using an adhesive present on specific capture organs (for review see ref. 1). Until recently, the mechanism of adhesion was completely unknown. In the case of *Arthrobotrys oligospora*, one of the most common nematophagous fungi, nematodes are trapped in three-dimensional structures of the adhesive network type (Fig. 1*a*). When a suspension of nematodes is added to an agar culture of the fungus, nematodes are immediately captured and firmly held by the traps. The nematode cuticle is lysed at the point of contact and penetrated by a hypha within one hour[2]. An increased secretion by the fungus of a mucilaginous substance in the presence of prey has been shown by scanning and transmission electron microscopy[2,3]. Our hypothesis is that the firmness of attachment to the traps despite the struggle of the nematode is due to a series of events, beginning with an interaction between complementary molecular configurations on the nematode and fungal surfaces. We show evidence here for the presence of a lectin on the traps of *A. oligospora* which binds to a carbohydrate on the nematode surface.

Developmentally regulated lectins have been identified in cellular slime moulds, and lectin activity is closely correlated with the development of cohesiveness between the cells[4–6]. Fungal lectins are produced in the symbiotic relationship between algae and fungi in lichens[7]. The role of lectins in other host-microorganism interrelationships, for example *Rhizobium*-leguminous plant associations, is well documented[8–11].

If a lectin-carbohydrate interaction is involved in this relationship, then pre-exposure of the lectin-carrying structure to specific carbohydrates would prevent attachment of the nematodes to the traps. As capture usually takes place within 30 min, microscopic observations at intervals during a 24-h period would give good information on the inhibitory effects of carbohydrates.

To investigate the nematode-trapping ability of *A. oligospora* Fres. (ATCC 24927), the fungus was grown on dialysis membrane on an agar surface[12]. The membranes were transferred to empty Petri dishes before capture of nematodes was tested to eliminate the effects of agar. To test inhibition of capture, cultures of the fungus were flooded with carbohydrate solutions for 24 h before addition of a water suspension of nematodes. Axenically cultivated bacteria-feeding nematodes (*Panagrellus redivivus* Goodey) were used throughout[3]. Alternatively, nematodes were suspended for 3–24 h in the same carbohydrate solutions, washed and added to untreated fungal cultures.

Flooding of the fungal colony with 20 mM *N*-acetylgalactosamine (GalNAc) resulted in total inhibition of capture over a 24-h period (Table 1). At this concentration capture was delayed by treatment with melibiose, whereas nematode-trapping ability was unaffected by all other carbohydrates. At higher concentrations of carbohydrates (200 mM) a less pronounced specificity was observed, as maltose, galactose and related sugars prevented capture. These results indicate low specificity of the lectin when exposed to high concentrations of carbohydrate and agree well with reports on the lectins from *Dictyostelium discoideum*[4,6]. In controls flooded with water or phosphate-buffered saline (0.15 M NaCl, 0.01 M potassium phosphate buffer, *p*H 7.2, PBS) total capture on dialysis membranes occurred within 30 min–3 h. Conversely, treatment of the nematodes with carbohydrates at 20 and 200 mM failed to inhibit capture. Therefore, the possibility that the carbohydrate-binding activity was located on the nematode was excluded.

The fact that nematode-trapping ability could be suppressed by preincubating the fungus with specific carbohydrates led to the conclusion that a lectin on the fungus is involved in, or responsible for, the interaction. A further consequence of this is that the surface of the nematode must offer suitable binding sites for the lectin, that is GalNAc groups must be present. Two series of experiments tested these hypotheses.

To see if the proposed trap lectin binds to a model prey, the fungus was grown on a piece of dialysis membrane and exposed to an excess of red blood cells (RBC). RBC from different blood groups carry different polysaccharides on their surfaces. Blood group A is characterised by a terminal GalNAc, B carries galactose and blood group O fucose. After incubation for 3–4 h at room temperature the membrane strips were carefully washed in PBS and observed under the microscope.

Significant attachment of RBC took place only at the capture organs (Fig. 1*b*). There was no marked difference between the blood groups, although group A showed a tendency to attach more easily. Thus the proposed trap lectin did not show strict specificity for GalNAc in these *in vivo* tests. As both galactose and fucose had some inhibitory effect on capture of nematodes (Table 1) this low specificity is expected. The developmentally regulated lectins isolated from *D. discoideum* showed a similar low specificity[4,6], and various degrees of specificity are reported for other lectins[13].

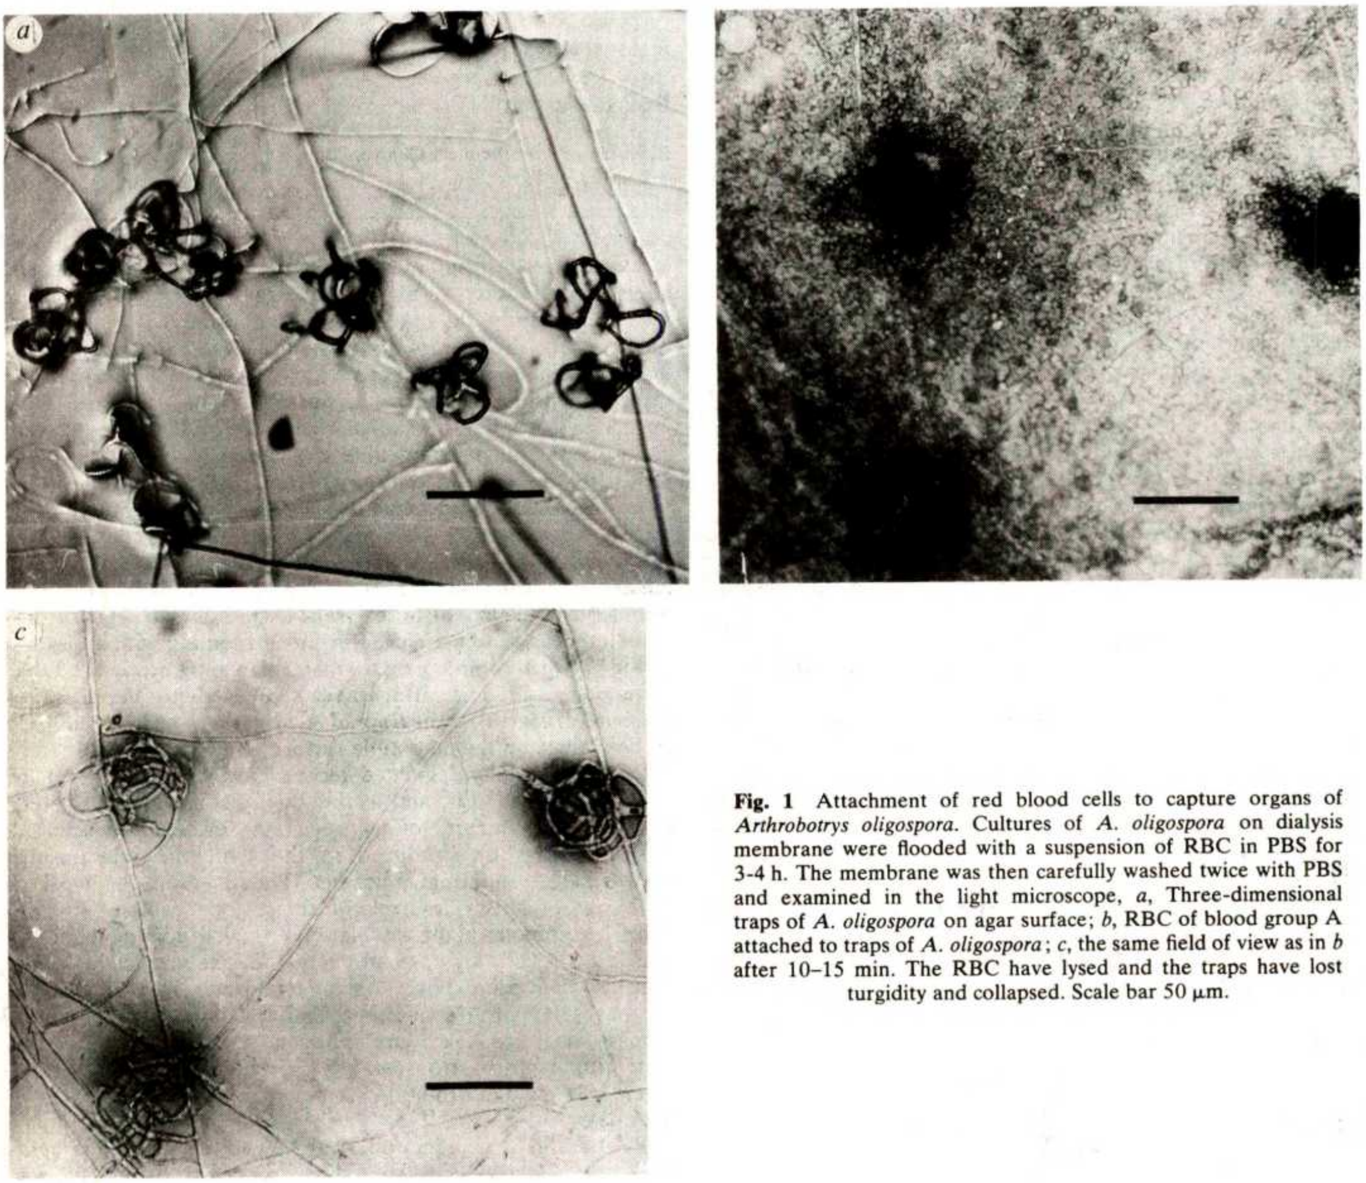

Fig. 1 Attachment of red blood cells to capture organs of *Arthrobotrys oligospora*. Cultures of *A. oligospora* on dialysis membrane were flooded with a suspension of RBC in PBS for 3-4 h. The membrane was then carefully washed twice with PBS and examined in the light microscope, *a*, Three-dimensional traps of *A. oligospora* on agar surface; *b*, RBC of blood group A attached to traps of *A. oligospora*; *c*, the same field of view as in *b* after 10–15 min. The RBC have lysed and the traps have lost turgidity and collapsed. Scale bar 50 μm.

Table 1 Effect of saccharides on the nematode-trapping ability of *Arthrobotrys oligospora*

Saccharide	Trapping ability at: 20 mM	200 mM
N-acetyl-D-galactosamine	–	ND
α-D-galactose	+	–
2-deoxy-D-galactose	+	–
fucose (6-deoxy-L-galactose)	+	(–)
N-acetyl-D-glucosamine	+	ND
α-D-glucose	+	+
2-deoxy-D-glucose	+	+
D(+)-mannose	+	+
α-methyl-D-mannoside	+	+
L-sorbose	+	–
D-fructose	+	+
L-xylose	+	+
D-arabinose	+	–
α-D-melibiose	(–)	–
lactose	+	–
maltose	+	–
D(+)-trehalose	+	+
sucrose	+	+

* The fungus was grown on strips of dialysis membrane[12] placed on the surface of a low-nutrient mineral salts medium[18]. Trap formation was induced by addition of a small amount of nematodes to 3–4 d old cultures. Trap-containing strips (7–14 d) were transferred to empty Petri dishes and flooded for at least 20–24 h with the appropriate carbohydrate (20 or 200 mM solution in distilled water or in phosphate-buffered saline). After removal of excess carbohydrate, 1–2 drops of a nematode suspension in water (approx. 1,000 nematodes ml^{-1}) were added to the fungal culture to test capture ability. Microscopic observations of capture were made after 30 min, 3 h and about 24 h. Results of 2–10 different experiments for each carbohydrate. +, normal capture; –, inhibition of capture; (–), capture delayed. ND, not determined.

It was observed that RBC, accumulated around the traps (Fig. 1*b*), lysed within 1 h. As lysis of RBC occurred to only a small extent spontaneously during these experiments, the effect was attributed to the trap. Immediately after RBC lysis the traps lost their three-dimensional appearance and collapsed. RBC stabilised by crosslinking with glutaraldehyde (80 μM for 6 h at about 20 °C) were captured by the traps in the same way as untreated cells but did not lyse.

It was not possible to determine the number of RBC bound per unit area or unit weight of fungal biomass in these *in vivo* tests. This was due to differences in trap size and distribution on the dialysis membranes between the experiments and to the irregular shape of the trap structures.

It seems that binding is achieved primarily by the GalNAc structure as inhibition of capture at the lower concentration of carbohydrate occurred only with GalNAc. To demonstrate GalNAc residues on the nematode surface, nematodes were exposed to a peroxidase–lectin conjugate prepared[14] with lectin from *Helix pomatia* with affinity for GalNAc[15]. As a blank, the nematodes were exposed to free peroxidase and otherwise treated identically. Incubation of nematodes in substrate (14 mM phenol, 0.8 mM 4-aminoantipyrine, 2 mM hydrogen peroxide) and assay for peroxidase activity[16] according to procedures developed for assay of particle-bound enzymes[17] showed that binding had taken place. Unspecific adsorption of free peroxidase to the nematode or inherent enzyme activity gave some background activity. However, peroxidase activity of conjugate-treated nematodes was approximately six times that of the peroxidase-treated controls. This was interpreted as indicating the presence of GalNAc residues on the nematode surface. Furthermore, on exposing the nematodes to the enzyme–lectin conjugate in the presence of free GalNAc, no activity above the background was observed.

We conclude that a developmentally regulated lectin is present on the traps of *A. oligospora* and binds to carbohydrates on the nematode surface as well as to RBC. The binding initiates an enzymatic alteration of both nematode and erythrocyte surfaces leading to penetration of the nematode cuticle by a hypha[2] and lysis of the RBC. The results contribute a new approach to the solution of the problem of specificity in this host–microorganism interrelationship.

N-acetyltransferase activity responds to environmental lighting in the eye as well as in the pineal gland

Sue Binkley, Michael Hryshchyshyn & Kathleen Reilly

Biology Department, Temple University, Philadelphia,
Pennsylvania 19122

N-acetyltransferase (NAT), which converts serotonin to N-acetylserotonin, is widely distributed in the vertebrate body[1,2]. In the pineal gland, however, NAT activity shows circadian changes which respond to environmental lighting both *in vivo* and *in vitro*[3,4]. NAT is responsible for rhythmic production of the pineal hormone melatonin, which functions in body colour changes[6], photoperiodic control of reproduction[7,8], and behavioural circadian rhythms[9,10]. The rhythmic changes in NAT have so far been thought unique to the pineal gland. Here we report data for ocular NAT showing a change in a daily light–dark cycle and modification by environmental lighting. The finding of light modified NAT in the eye is significant because it may explain the failure of some investigators[11] to find effects of pinealectomy and it may also explain the occurrence of rhythmic melatonin in the blood of some species after pinealectomy[12–14]. The prerequisites for the production of melatonin exist in the eye as well as in the pineal gland: serotonin[15], hydroxyindole-*O*-methyltransferase activity[16] and *N*-acetylindole[17] are present. Furthermore, labelled serotonin is converted to melatonin by the retina *in vitro*[18]. Our finding of NAT and its modification by light and dark completes the argument for ocular capacity for melatonin production in a cyclic manner modified by environmental lighting.

In our experiments the eyes and the pineal gland were investigated in parallel by assaying both structures from animals during light–dark treatments. The data in Fig. 1 (and in two to four replicate experiments) illustrate the following statistically significant results ($P < 0.05$): (1) In a light–dark cycle, dark-time NAT was 7.0–11.8 times as high as light-time NAT in the pineal gland; dark-time NAT was 2.7–2.9 times light-time NAT in the eye. (2) When chicks were placed in constant dark (DD), pineal NAT in their subjective dark-time was 3.7–5.9 times that in the

0028-0836/79/410479—03$01.00

Table 1 Ocular NAT in four species was measured in the light and dark times of a light–dark cycle (LD12:12)

	N-acetyltransferase activity (nmol per eye per h) Light	Dark
Chick, *Gallus domesticus*	3.038 ± 0.122	8.726 ± 0.898
Rat, *Rattus norvegicus*	0.475 ± 0.066	1.322 ± 0.148
Sparrow, *Passer domesticus*	0.119 ± 0.029	0.483 ± 0.053
Hamster, *Mesocricetus auratus*	0.726 ± 0.148	0.527 ± 0.132

Values are means ±s.e.m., $N = 4$.

light-time; in contrast, in the eye, subjective dark-time NAT was not significantly different from subjective light-time NAT. (3) When the chicks were placed in constant light (LL) subjective pineal dark-time NAT was suppressed (to 25–27% of its LD value); ocular dark-time NAT was likewise suppressed (to 35–38% of its LD value). (4) NAT shows a 'rapid response' to light during the dark-time[19,20]. Chicks were exposed to light for 1 h during their subjective dark-time which suppressed dark-time pineal NAT (61–76%) and also suppressed ocular NAT (36–59%).

The specific activity of NAT in the pineal gland was up to three times that in one eye during the dark-time. Table 1 shows data for four species kept in light–dark cycles. The chick, the sparrow, and the rat all had ocular dark-time NAT three to four times higher than ocular light-time NAT. The data for ocular NAT and its modulation by environmental lighting are convincing evidence that the pineal gland is not singular in its ability to metabolise serotonin and produce melatonin in a rhythmic fashion.

In the experiments reported here—two-point experiments—there was no evidence that the ocular NAT has a persistent circadian rhythm in the same conditions where such a rhythm clearly occurs in the pineal gland. Nor did the eye of the hamster have an NAT rhythm in the LD cycle. However, these two-point experiments are not conclusive evidence that there is no circadian rhythm—it is possible to miss a narrow peak of activity even with more frequent time points.

When NAT activity in the two eyes was compared the values were positively correlated ($r = 0.82$ calculated for six pairs from LD chicks). In the experiments detailed in Fig. 1 and Table 1, NAT was measured in the neural retina plus the pigmented layer plus the accompanying wetting vitreous humor. In a separate experiment done to partition the NAT activity (Table 2), 41–56% of NAT was localised in the neural retina and 42–57% was in the pigmented layer; only 2% was in the 10-μl sample of vitreous humor (used to estimate the accompanying wetting of the neural retina and pigmented layers by humor during the dissection). As whole eyes were not analysed, the measurements do not represent the total ocular melatonin synthesising capacity. Bubenik *et al.*[17] localised *N*-acetylindole to the outer layer of the neural retina.

To make physiological sense of the relative contributions of pineal and ocular melatonin requires knowledge of the target(s) and functions of melatonin. Melatonin synthesis by the eye could be an endocrine function, or, alternatively, the eye itself may be the target. For endocrine function, the eye may be an additional source of melatonin which acts in the circulation as a hormone augmenting pineal production.

Table 2 NAT was measured separately in the three portions of the eye which were used together for the experiments in Fig. 1 and Table 1

	N-acetyltransferase activity Light	Dark
Eye		
Vitreous humor	0.070 ± 0.027	0.144 ± 0.065
Neural retina	1.654 ± 0.270	9.678 ± 1.157
Pigmented layer	2.304 ± 0.350	7.409 ± 0.777
Pineal gland	2.632 ± 0.451	22.099 ± 4.374

Each value is a mean ($N = 4$) ±s.e.m. NAT is given as nmol per tissue per h for the neural retina and pigmental layer (one eye), as nmol per gland per h for the pineal gland, and as nmol per 10μl per h for the vitreous humor.

There are several hypothetical roles for melatonin within the eye itself. Ocular melatonin may function in the daily rhythms reported for outer disk shedding in the retina[21]. Two types of movement have been noted in the eyes of lower vertebrates and some birds: retinal cones elongate and shorten[22], and pigment migration is thought to occur in the melanin containing cells[23]. The melanin pigment layer widens in the dark and narrows in the light—pinealectomy abolishes the dark displacement of pigment, melatonin increases the displacement[23]. The cones shorten in the light and lengthen in the dark—short-term effects which are superimposed on an underlying circadian rhythm which persists in constant light or constant dark[22,24].

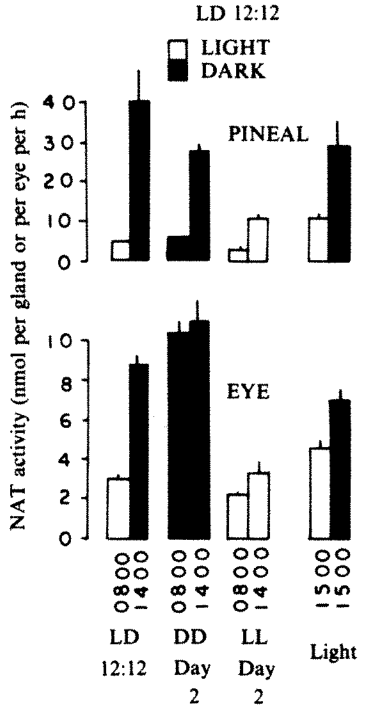

Fig. 1 NAT activity in the eyes and pineal glands of chicks kept in a light–dark cycle (LD), constant dark (DD) or constant light (LL). Chicks were kept in a light–dark cycle, LD12 h : 12 h, lights-off 1000, from day 1 after hatching until they were 23 days of age. The chicks were then divided into groups and kept for 2 more days in either the same LD cycle, DD or LL. On the second day they were killed at 0800 (subjective day-time) or at 1400 (subjective night-time). A fourth group of chicks were kept in the LD cycle but exposed to light for one hour (1400–1500) during their subjective dark-time—this group and controls kept in the dark were killed at 1500. The data shown here are from one of two replicate experiments ($N = 4$ chicks per group, bars represent mean values ±s.e.m.); the LD experiment was performed four times. For these experiments the combined neural retina plus pigmented layer was dissected from the eyes immediately after the chicks were killed. The ocular tissue and pineal glands were then quick frozen on dry ice and assayed for NAT within a week[5].

We conclude that the eye is capable of rhythmic melatonin synthesis (in the chick, sparrow and rat), and that the chick ocular NAT is modified by environmental lighting (constant light, dark-to-light transitions). It is probable that ocular melatonin gets into the bloodstream, because some pinealectomised animals have rhythmic melatonin circulating after pinealectomy[12–14].

This investigation was supported by NSF grant PCM 77-26474 to S.B. and a Faculty Research Award to S.B. from Temple University. We thank Joel Sheffield, Beth Bernside and Sue Klein for their assistance.

Note added in proof: Hamm and Menaker (personal communication) have evidence that the ocular NAT rhythm is circadian with a later and narrower peak on the second day of constant dark; we now have evidence for circadian clock involvement from light-to-dark transition experiments.

Modulation of juvenile hormone synthesis by an analogue in the cockroach

S. S. Tobe

Department of Zoology, University of Toronto, Toronto, Ontario, Canada M5S 1A1

B. Stay

Department of Zoology, University of Iowa, Iowa City, Iowa 52242

The juvenile hormones (JH) are novel insect sesquiterpenoid products synthesised by paired endocrine glands known as the corpora allata (CA). These glands are innervated by neural and neurosecretory elements originating in the central nervous system (CNS)[1–3] and are known to undergo predictable changes in synthesis and release of JH during the reproductive cycle[4–8]. This implies that the CA are regulated by intrinsic physiological signals. For example, in the viviparous cockroach, *Diploptera punctata*, if the haemolymph titres of JH are experimentally altered by removal of one member of the pair or by implantation of additional CA, the original CA undergo appropriate corrective responses in JH synthesis[9,10]. This is partly due to signals from the CNS because denervation of the CA attenuates the compensatory change[10]. The depression in JH synthesis after addition of exogenous JH to the system has also been observed[11,12]. However, there have been no direct measurements of JH synthesis following treatment with exogenous JH analogues *in vivo*. We show here that in *Diploptera punctata*, topical application of a JH analogue (JHA) depresses the synthesis of JH at high doses but stimulates synthesis at low doses and that the analogue can support oocyte growth and maturation in the absence of the CA and that application to intact animals stimulates oocyte growth rates. These results indicate that the analogue can replace authentic JH.

Mated females of *Diploptera punctata* were allatectomised between 1 and 5 h after adult ecdysis[9]. Three to four days later, the JH analogue ZR512 (ethyl (2*E*, 4*E*)-3,7,11-trimethyl-2,4-dodecadienoate, Zoecon) was applied in 5 μl of acetone to the dorsal surface of the abdomen (wings were removed). The mean weight of these females was 190±3 mg. Figure 1 shows a semi-logarithmic plot of ZR512 dose against the basal oocyte length 6 days after analogue application. At 2.5 μg the oocyte response was slightly greater than that of the controls but not significantly different; between 10 and 100 μg it was virtually linear; at 200 μg the oocytes attained maximum mature length (1.65 mm) with 80% chorionated, ready for oviposition. Oviposition was elicited in 6 of the 7 females treated with 200 μg and in 5 of the 9 females receiving 100 μg ZR512. None of the females treated with acetone ($n = 9$), 25 μg ($n = 10$), or 10 μg ($n = 5$) ZR512 oviposited. From these observations we conclude that a single topical application of ZR512 (≥ 100 μg) in acetone effectively mimics the action of JH in *Diploptera punctata*, permitting both oocyte maturation and oviposition in the absence of authentic hormone.

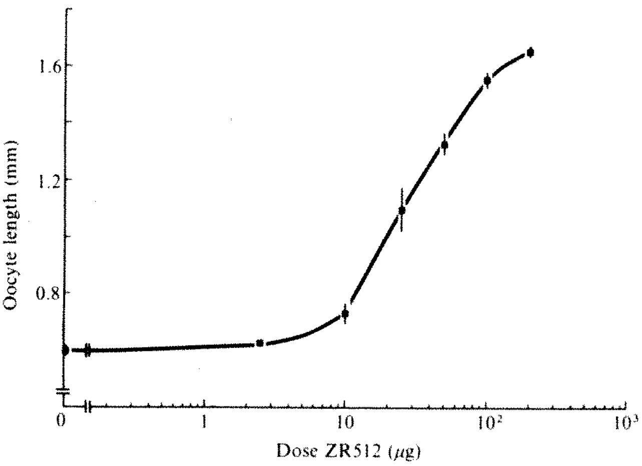

Fig. 1 Basal oocyte length on day 6 after treatment of allatectomised female *D. punctata* with ZR512. Oocytes attained mature length with the 200-μg dose. Each point represents the mean ± s.e.m. of determinations on 5–10 animals.

To test the effects of this analogue on the rate of JH synthesis by the CA, normal mated females were treated with various doses of ZR512 between 1 and 5 h after adult emergence. Every day for six days after the treatment, the length of the basal oocytes was recorded and the rate of C_{16}JH (JH III) synthesis by the CA was assayed[4,5]. Figure 2*a* shows the progress of egg growth for 100, 25 and 2.5-μg doses of ZR512, and acetone-treated controls. The rate of oocyte growth showed a positive correlation with the concentration of ZR512 applied. The difference between oocyte lengths in 25 μg- and 100 μg-treated animals and controls is significant for days 2–6 ($P < 0.001$; Students *t*-test), whereas in animals treated with 2.5 μg, although the oocytes were larger than controls on days 2–5, only on day 4 is the difference significant ($0.02 < P < 0.01$). These results indicate that exogenously applied analogue may act with JH released by the CA to raise the titre of JH–JHA such that eggs grow more rapidly in treated animals than in controls. (For example, the control females had 1.33 mm-long oocytes on day 5 whereas this length was achieved at 4.25, 3.25 and 2.75 days in females treated with 2.5, 25 and 100 μg of analogue respectively.) Alternatively, the ZR512 may stimulate the CA to synthesise JH at a greater rate, causing an elevation in JH titre.

The choice between these hypotheses is facilitated by the *in vitro* determination of the rate of JH synthesis by the CA of the same animals for which egg growth is shown (Fig. 2*a*). These measurements provide an estimation of the contribution of endogenous JH towards the increased rate of oocyte growth (Fig. 2*b*). At 100 μg ZR512, the normal cycle of JH synthesis was depressed, reaching a maximum rate of only 28 pmol per h per pair on day 3 and minima on days 2 and 5 of 6–7 pmol per h per pair. Animals receiving 25 μg of ZR512 showed rates of JH synthesis similar to those of acetone controls on days 2–4 but depressed rates thereafter (maximum rate of JH synthesis 54 pmol per h per pair). Maximal rates of JH synthesis (87 pmol

0028–0836/79/410481—02$01.00

per h per pair) by CA of control animals were observed on day 6. On the basis of oocyte lengths attained by this time (Fig. 2*a*) and from control measurements reported elsewhere[9,10], this value probably represents the peak of the normal cycle. In sharp contrast to the depression of JH synthesis by 100 and 25 µg doses of ZR512, animals receiving 2.5 µg of ZR512 showed a marked stimulation in JH synthesis on day 4 (126 against 49 pmol per h per pair) ($P = 0.028$). Similar stimulation on day 4 has been observed after treatment with 2.5 µg C_{16} JH (unpublished data). We conclude that the high doses of ZR512 depress synthesis of JH, whereas the low dose stimulates synthesis. The accelerated oocyte growth observed at high doses of ZR512 seems to be due to the cumulative action of the analogue and endogenous JH on the oocytes causing an elevation in the titre of JH-active compounds.

To account for these opposing actions of the applied hormone analogue, we hypothesise that below a certain dose, JH synthesis is stimulated by the analogue, (that is, shows positive feedback) and that at a higher dose, a negative feedback operates to depress JH synthesis. Such a hypothesis would also account for the increase in rates of JH synthesis after unilateral allatectomy and the suppression of JH synthesis in the presence of supernumerary CA[9,10] and for the rapid changes in JH synthesis during the normal reproductive cycle[5]. For example, a positive feedback loop may be responsible for the rapid increase in JH synthesis observed in normal females between days 3 and 5 after emergence[5]. Such loops have been proposed for insect endocrine systems, particularly for the interaction between the CA and cerebral neurosecretory cells[13–16] and between the prothoracic glands and cerebral neurosecretory cells[17–19]. However, definitive proof for such pathways in insect systems has been lacking, although they are well known in vertebrate systems—for example the preovulatory surge of luteinising hormone which occurs as a result of increasing titres of estradiol[20]. It is significant that in *D. punctata* the proposed positive feedback loop responsible for the stimulation of JH synthesis in animals treated with 2.5 µg ZR512 operates only for a short period during the reproductive cycle, with a maximum effect on day 4. This is precisely the time at which rates of JH synthesis are rapidly increasing in control animals[5]. This suggests the existence of a temporal gate in the centre which regulates the CA—thus the regulatory centre may be sensitive or responsive to increasing titres of JHA only for a brief period during the reproductive cycle.

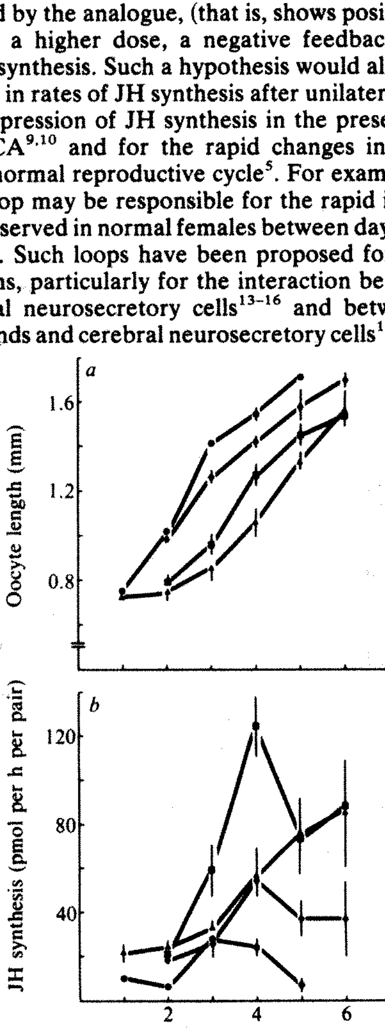

Fig. 2 The effect of ZR512 on oocyte growth and JH synthesis in *D. punctata*. Animals were treated topically on day 0 and assayed on days 1–6. *a*, Mean oocyte lengths ±s.e.m.; *b*, mean rates of JH synthesis ±s.e.m. $n = 5$, except for day 4 where $n = 10$ and day 5 where $n = 10$ for 2.5 µg, $n = 9$ for 25 µg and acetone and $n = 7$ for 100 µg. Rates of synthesis of C_{16}JH were determined using an *in vitro* radiochemical assay which uses the incorporation of the methyl moiety of [^{14}C-methyl]methionine into C_{16}JH. Individual pairs of CA were incubated for 3 h at 28 °C in medium 199 (Hanks' salts; with glutamine, HEPES buffer, 25 mM, *p*H 7.2-GIBCO) plus Ficoll (20 mg ml^{-1}) to which [^{14}C-methyl]methionine (Amersham-Searle, final specific activity 35–39 mCi mmol^{-1}) was added. Procedures for the preparation of the incubation medium, and the separation and quantitation of biosynthesised radiolabelled JH have been described previously[4–5]. ●, 100 µg 2R512; ◆, 25 µg 2R512; ■, 2.5 µg 2R512; ▲, acetone.

These results also demonstrate that high doses of JHA suppress JH synthesis by the CA. Implantation of supernumerary CA[9,10], as a source of JH, as well as topical treatment with C_{16}JH (unpublished data) also result in a reduction in JH synthesis. The simplest explanation for this suppression is a negative feedback loop. Such mechanisms are well known in the regulation of endocrine gland function.

These feedback signals may operate on an intermediate regulatory centre outside the CA but it is conceivable that the signals may also feed back directly on the CA. However, Pratt and Finney[21] did not observe inhibition of JH synthesis by C_{16} JH *in vitro* in *Periplaneta americana*. On the other hand, we have shown that isolation from the regulatory centres of the CNS by denervation of the CA attenuates but does not totally abolish corrective responses by the CA[9,10] and, although this may suggest a feedback loop operating directly on the CA, it is equally likely that a regulatory centre outside the CA may be controlling the glands via a humoral pathway.

Although the mode of action of ZR512 still remains to be defined precisely, it is clear that, at high doses, it can be regarded as a suppressor of JH synthesis. Using the *in vivo–in vitro* assay described here, it is now possible to screen JH analogues for such activity. Those analogues which suppress CA activity but have no gonadotrophic activity may have potential as insect control agents. The only compounds known to have such activity are the precocenes[22,23] but their mode of action is unclear.

Our assay differs from other screening procedures[21–24] in that it permits a simultaneous assessment of analogues as inhibitors of both JH synthesis and ovarian growth in the same insect. The techniques described here should also be valuable for investigating the role of the centres outside the CA in regulating these endocrine glands.

This study was supported by the Natural Sciences and Engineering Research Council of Canada. We thank Dr G. Staal for ZR512.

FSH stimulates hyaluronic acid synthesis by oocyte–cumulus cell complexes from mouse preovulatory follicles

John J. Eppig

The Jackson Laboratory, Bar Harbor, Maine 04609

A surge in the secretion of gonadotropins stimulates several processes in mammalian preovulatory follicles, including oocyte maturation, cumulus expansion (mucification) and ovulation. This surge results in increased circulating levels of both luteinising hormome (LH) and follicle-stimulating hormone (FSH). It has generally been thought that LH is primarily responsible for the stimulation of the maturational processes in preovulatory follicles that results in ovulation and corpus luteum formation, and that FSH stimulates the development of the next wave of preovulatory follicles. A direct role for FSH in preovulatory events has been unclear. However, two studies have suggested that FSH is essential for certain preovulatory processes. First, there is evidence that the production of plasminogen activator by granulosa cells is more sensitive to FSH than to LH[1]. Plasminogen activator could convert follicular fluid-borne plasminogen to plasmin, a protease capable of weakening the follicle wall[2]. Second, highly purified FSH, but not highly purified LH, stimulates cumulus expansion by isolated mouse oocyte–cumulus cell complexes[3]. A critical step in cumulus expansion is the deposition of a hyaluronic acid matrix, so that the synthesis of this glycosaminoglycan is very important in the preparation of the mouse oocyte–cumulus cell complex for normal ovulation. I report here that the synthesis of hyaluronic acid *in vitro* is stimulated by FSH but not by LH.

Biological grade preparations of FSH and LH stimulated hyaluronic acid synthesis by isolated mouse oocyte–cumulus cell complexes in a dose-dependent fashion (Fig. 1*a*). However, the complexes were much more sensitive to FSH than to LH, suggesting that the response to biological grade LH was due to contamination with FSH. To test this idea, the complexes were incubated in highly purified rat FSH and LH. The former, but not latter, significantly ($P < 0.01$) stimulated hyaluronic acid synthesis (Fig. 1*b*). Similarly, highly purified human chorionic gonadotropin (HCG), which competes for the same binding sites as LH[4], did not stimulate hyaluronic acid synthesis (Fig. 1*b*). As crude HCG significantly ($P < 0.01$) stimulated the synthesis of hyaluronic acid (Fig. 1*b*), this preparation is probably contaminated with chorionic FSH. Treatment of FSH-stimulated complexes with *Streptomyces* hyaluronidase indicated that 90% of the ^{3}H-glucosamine incorporated into cetylpyridinium chloride-precipitable counts was incorporated specifically into hyaluronic acid (Fig. 1*b*). Dibutyryl cyclic AMP, theophylline and cholera toxin all significantly ($P < 0.01$) stimulated hyaluronic acid synthesis (Fig. 1*c*).

It is concluded that FSH, and not LH, stimulates the synthesis and deposition of hyaluronic acid by isolated mouse oocyte–cumulus cell complexes. Therefore, FSH plays a direct, critical role in an important event, hyaluronic acid synthesis, that is essential for the cumulus expansion preceding normal ovulation. This is the first demonstration of a specific biosynthetic process, related to the ovulatory process, that is stimulated directly by FSH and cannot be directly stimulated by LH. The finding that dibutyryl cyclic AMP, theophylline (an inhibitor of cyclic AMP degradation) and cholera toxin (a stimulator of cyclic AMP synthesis) all stimulated hyaluronic acid synthesis suggests that the action of FSH is probably mediated by cyclic AMP.

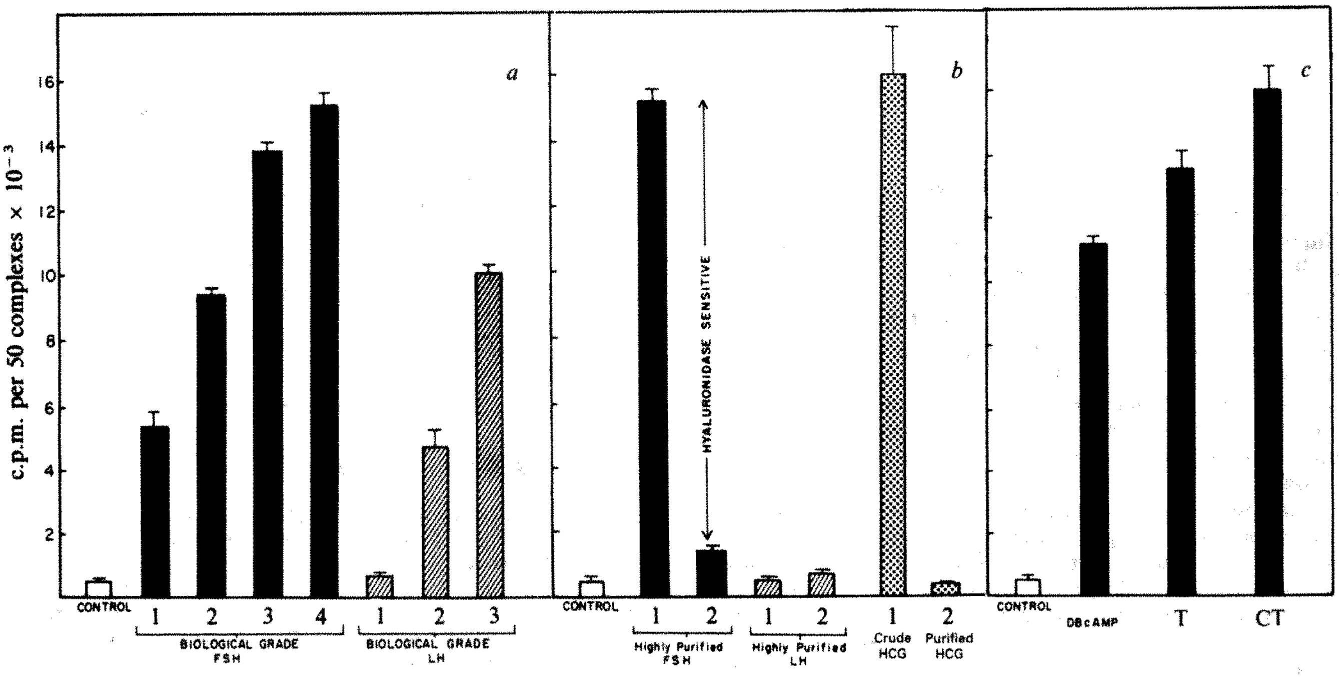

Fig. 1 (C57BL/6J × LT/Sv)F$_1$ mice, 26–28-d-old, were injected with 5 IU of pregnant mare serum gonadotropin. Forty-eight hours later the large graafian follicles were punctured with 25-gauge needles and the oocyte–cumulus cell complexes were removed and washed by serial passage, using micropipettes, through four dishes containing 2.0 ml of Whitten's medium[6] supplemented with 5% fetal bovine serum (Sterile Systems Inc.). Hormones and isotope were added to a culture dish containing 2.0 ml of medium and incubated for 17 h at 37 °C in an atmosphere of 5% O_2, 5% CO_2 and 90% N_2. The following hormones were added at various concentrations: *a*, biological grade FSH (NIAMDD-rat FSH-B1), 0.1 μg ml^{-1}(1), 0.5 μg ml^{-1}(2), 1.0 μg ml^{-1}(3), 5.0 μg ml^{-1}(4); biological grade LH (NIAMDD-bovine LH-B10), 1.0 μg ml^{-1}(1), 5.0 μg ml^{-1}(2), 10.0 μg ml^{-1}(3); *b*, highly purified FSH (NIAMDD-rat FSH-I-4), 1 μg ml^{-1}(1, 2); highly purified rat LH (NIAMDD-rat LH-I-4), 1 μg ml^{-1}(1), 5 μg ml^{-1}(2); crude HCG (Sigma), 5 IU ml^{-1}; highly purified HCG (R. E. Canfield preparation CR-119), 5 IU ml^{-1}; *c*, dibutyryl cyclic AMP, 5 mM (DBcAMP, Sigma); theophylline 5 mM(T, Sigma); cholera toxin 2 μg ml^{-1}(CT, Sigma). Hyaluronic acid synthesis was measured exactly as described by Solursh[7], in groups of 50 oocyte–cumulus cell complexes incubated in medium containing 25 μCi ml^{-1} of D-[6-^{3}H]glucosamine hydrochloride, specific activity 38 Ci mmol^{-1} (Amersham) for 17 h. Specificity of isotope incorporation into hyaluronic acid was determined by sensitivity of the labelled material to highly specific *Streptomyces* hyaluronidase[8]. After the 17-h labelling period some groups of the washed complexes were incubated in 5 IU ml^{-1} *Streptomyces* hyaluronidase (Calbiochem) at 37 °C for 3 h and then assayed according to Solursh[7]. At least three groups of 50 complexes were assayed for each group. Data are expressed as c.p.m. per 50 complexes ± s.e.m., and were subjected to one-way analysis of variance followed by the Student–Newman–Keuls multiple range test.

0028–0836/79/410483—02$01.00

Although LH is ineffective in stimulating hyaluronic acid synthesis *in vitro*, an indirect role for LH in regulating cumulus expansion *in vivo* cannot be excluded. The follicular fluid of preovulatory follicles contains significant amounts of FSH before the LH surge[5], but this FSH does not stimulate cumulus expansion before the gonadotropin surge. Perhaps LH affects the preovulatory follicle in some way that permits the oocyte–cumulus cell complex to respond to FSH and synthesise hyaluronic acid.

Unmasking of fetal determinants on adult bone marrow cells

C. H. Granatek*

Department of Development Therapeutics

B. M. Scheinberg & P. M. Corry

Department of Physics, The University of Texas System Cancer Center,
M. D. Anderson Hospital and Tumor Institute, Houston, Texas 77030

The phasing-out of an SV40 cross-reactive fetal antigen in the developing hamster fetus after day 10 occurs concomitantly with an increase of bound sialic acid in membrane, microsomal and soluble cell fractions[1]. A masking phenomenon is suggested by the fact that the antigen can be uncovered on older fetal tissue by trypsinisation[2]. Similarly, a murine oncofetal antigen under study in our laboratory is optimally expressed on the haematopoietic stem cells of the fetal liver at the 15th day of gestation[3], just before the onset of haematopoiesis and collagen production in the spleen[4]. The expression of this antigen on human leukaemic blast cells has, furthermore, been correlated with low levels of sialic acid on the surface of these tumour cells[5]. As fetal determinants can be expressed on adult bone marrow in disease states not involving malignant transformation[6], it is of interest to know whether production of this oncofetal antigen is repressed, or whether the determinants are in cryptic form at the plasma membrane due to some masking phenomenon. The investigation described here demonstrates that determinants which cross-react immunologically with fetal liver tissue can be enzymatically unmasked on normal adult murine haematopoietic stem-cell surfaces. This finding suggests that the expression of these oncofetal antigens on malignant cells does not depend on *de novo* production of the antigens, and that these determinants may play some part in normal differentiation control mechanisms.

We used adult bone marrow (ABM) cells from the femurs of 16-week-old male mice and 15-day fetal liver (FL) cells from fetuses of primigravida BALB/c and C57BL/6 mice. Following fractionation on a discontinuous albumin gradient to isolate the haematopoietic stem-cell fractions[7], ABM or FL stem cells were incubated individually or in sequence with collagenase (Calbiochem; grade A) and neuraminidase (Behring, from *Vibrio cholerae*) at 37°C for 30 min per enzyme. Cells were washed three times after each incubation. Collagenase incubation and washes were carried-out with 0.05 M Tris-HCl buffer, *p*H 7.6, containing 0.005 M $CaCl_2$. Neuraminidase buffer, *p*H 7.2, contained 0.004 M Na acetate, 0.116 M NaCl and 0.005 M $CaCl_2$. Enzyme incubations were carried out with constant mixing of cell suspensions on a Junior Orbit bath shaker at 200 r.p.m.

Subsequently, the enzyme-treated target (ABM and FL) cells were incubated with normal rabbit serum or with a rabbit antiserum which was raised against BALB/c FL cells (10^7 cells, subcutaneously, weekly for 10 weeks) denoted as rabbit anti-mouse fetal liver serum. After appropriate absorptions, this latter antiserum did not react with adult murine spleen, liver or ABM cells. Indirect immunofluorescence was then carried out using a previously described method[5]. Cells for the electron microprobe (X-ray fluorescence) analysis were reacted with ferritin-tagged antibody or normal globulin. Single cells were analysed in a modified Hitachi HU 10A transmission electron microscope which was adapted with a high resolution lithium-drifted silicon (Si(Li)) detector. Computer analysis of the intensity of the $K\alpha$ peak for iron (6.4 KeV) determined the number of ferritin-tagged antibody molecules bound by cell membrane determinants[8,9]. The quantitative expression of fetal antigen determinants was correlated to the respective enzyme treatment(s).

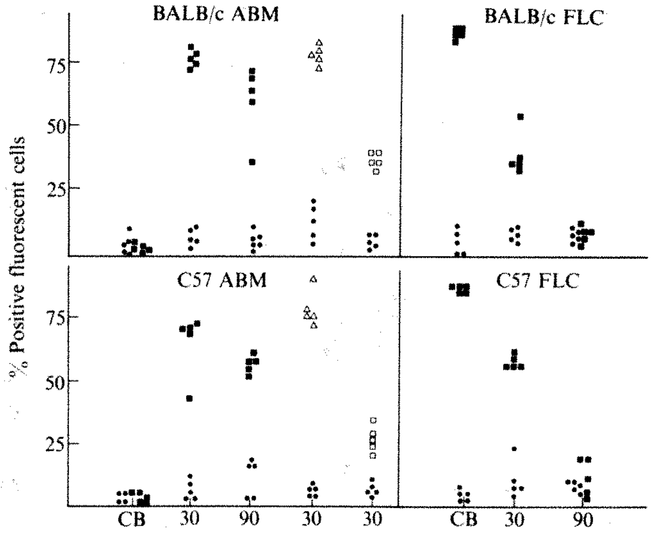

Fig. 1 Enzymatic modulation of cell-surface expression of fetal antigen determinants assayed by indirect immunofluorescent labelling. Mouse ABM or FL cells were treated with control buffer (CB) or with 30 or 90 U collagenase, followed by 12.5 U neuraminidase, and then incubated with normal rabbit serum (●), rabbit anti-mouse fetal liver serum (■), antiserum absorbed with adult mouse tissue (△) or antiserum absorbed with mouse fetal liver (□). Each point represents one experiment evaluating 100 cells.

Figure 1 demonstrates the effect of sequential incubations of ABM cells with collagenase and neuraminidase. The optimal regimen for uncovering fetal determinants on BALB/c ABM cells was 30.0 U collagenase followed by 12.5 U neuraminidase. After this enzyme treatment 80% of the ABM cells were labelled by rabbit anti-mouse fetal liver serum. There was no

* ABM Adult bone marrow; FL, fetal liver; RAMFLS, rabbit anti-mouse fetal liver serum; NRS, normal rabbit serum.

† Target cells were incubated with 30 U collagenase (C) and 12.5 U neuraminidase (N), each for 30 min at 37°C, in the sequence indicated.

‡ Mean ± s.d.; $n = 50$ for X-ray fluorescence, assays done one cell at a time; $n = 100$ for immunofluorescence (IF), assays repeated five times.

increase in nonspecific labelling of cells by normal rabbit serum. C57BL/6 ABM cells reacted in the same manner, showing that detection of the fetal determinants was not restricted to $H\text{–}2^d$ allelic expression. The reverse enzyme sequence or treatment with either enzyme alone did not increase the reactivity of the ABM cells with the rabbit antiserum.

The rabbit anti-fetal serum was absorbed twice with FL cells (10^7 cells ml^{-1}, 1 h at 37°C, 16 h at 4°C), and then incubated with syngeneic (either BALB/c or C57BL/6) ABM cells which had been subjected to the optimal enzyme regimen. As shown in Fig. 1, the number of unmasked ABM cells labelled by the absorbed serum fell by 50% for BALB/c and by 67% for C57BL/6 cells. Specificity controls showed that absorption with other adult cells (spleen, liver, intestine or thymus) produced no reduction in labelling of unmasked ABM by the antiserum. Furthermore, these tissues were not labelled by the antiserum after similar enzyme treatment.

As demonstrated in Fig. 1, rabbit antiserum reacted optimally with fetal liver cells which were not enzymatically modified (90% fluorescent cells). The incubation of FL cells with collagenase followed by neuraminidase resulted in a decrease in the number of cells labelled by the antiserum as the concentration of collagenase was increased. In contrast to ABM cells, fetal antigen expression on FL cells could be modified by treatment with either enzyme alone.

X-ray immunoflurescence spectrometry has allowed measurement of the rabbit antiserum-reactive determinants on the cell surface (Table 1). Fetal determinants expressed on untreated FL cells averaged 10^6 determinants per cell. ABM cells at the optimal conditions for unmasking displayed approximately an order of magnitude fewer determinants than the FL cells. Untreated ABM cell controls or ABM cells treated with neuraminidase followed by collagenase displayed approximately 10^4 determinants per cell (2 orders of magnitude below untreated FL cells). Table 1 also presents data comparing the number of cells which displayed significant antibody binding (>95% confidence) as determined by X-ray fluorescence with the number of positive cells in the indirect immunofluorescence assay. Although the reactivity of anti-fetal serum for unmasked ABM was not completely abolished in the indirect fluorescence assay after absorption with FL cells, X-ray analysis revealed that the percentage of positive cells and the number of fetal determinants per cell labelled by the absorbed antibody were comparable to background levels with normal rabbit serum.

The mechanism(s) responsible for the unmasking of fetal determinants on the surface of the ABM cell, or for their removal from the FL cell surface, has not been determined. In our system for unmasking, collagenase treatment must precede neuraminidase. After collagenase has acted on its substrate(s), neuraminidase can cleave sialic acid. Whether the cleavage of sialic acid occurs from unmasked glycoprotein, glycolipid or some other macromolecules was not determined. The unmasking may be caused by simple removal of components from the cell surface or could also involve conformational changes at the plasma membrane. An enzymatic function is presumed necessary because heat-inactivated enzymes were ineffective. Other proteolytic enzymes (papain and trypsin) were tested (alone or in combination with neuraminidase) and failed to achieve similar unmasking.

The phenotypic expression of fetal haematopoietic stem-cell determinants on the ABM cell surface after enzymatic unmasking suggests that their transcription is not repressed by the ABM cell. The unmasking of fetal determinants on ABM cells by collagenase and neuraminidase was unique among the tissues studied (adult intestine, liver, spleen and thymus) and enzymes tested. However, it is possible that the expression of these or similar determinants may occur in other conditions, for example, as a function of differentiation or de-differentiation–skin[10,11], muscle and lung fibroblasts[12] have all been shown to express fetal determinants when cultured *in vitro*.

Mid-gestation fetal liver cells cross-react immunologically with a variety of viral and chemically induced animal tumours[13–15], as well as with human malignant melanoma[16], leukaemia[5,16] and colon carcinoma[17]. As transformed cells of various histological types express fetal determinants, it may be physiologically significant that only adult bone marrow cells were demonstrated to carry these determinants in a cryptic fashion.

A virus-free immunogen effective against Epstein-Barr virus

David A. Thorley-Lawson

Sidney Farber Cancer Institute, Harvard Medical School, 44 Binney Street, Boston, Massachusetts 02115

Epstein–Barr virus (EBV)-associated diseases—infectious mononucleosis (IM), nasopharyngeal carcinoma (NPC) and Burkitt's lymphoma (BL)—constitute considerable world health problems. EBV infection occurs in all human populations and is accompanied by seroconversion and life-long persistence of the virus[1]. The antibodies present as a consequence of infection are considered important in controlling the persistent viral infection and in preventing recurrent bouts of IM which is known to be caused by the virus[2]. As EBV infection during childhood does not usually result in illness[20], only seronegative adolescents and young adults are susceptible to IM. Similarly, the groups at risk to EBV-associated neoplasms are known. The first group includes children in areas of hyper- and holoendemic malaria in Africa[3], where BL is the most common childhood cancer. The other group consists of people, particularly men, of the HLA-2 and Sin 2 haplotypes[4], of southern Chinese origin amongst whom NPC is the most common tumour[5]. It has been suggested that an anti-EBV vaccine should be developed[6], and this debate has been stimulated recently by a study further implicating EBV with African BL[7]. I report here the successful production of a DNA-free immunogen which may be readily prepared in large quantities and will successfully invoke a strong neutralising anti-EBV response in experimental animals. This material could form the basis for developing an anti-EBV vaccination programme.

A vaccine against EBV has been considered for several reasons. First, vaccines made from viral antigens have proved highly successful in protecting against tumours caused by Marek's disease herpesvirus in chickens[8] and by herpesvirus saimiri in marmosets[9]. Second, as stated above, EBV-associated diseases constitute considerable world health problems[2,3,5] and the populations at risk have been defined. Thirdly, the significance of EBV as a tumorigenic agent in humans could be finally established if it were possible to prevent tumours by vaccination.

Work in this laboratory has been concerned with studying the biochemical nature of the EBV-associated membrane–neutralising antigen complex and using this information to develop an effective anti-EBV vaccine. It was shown previously that a rabbit anti-EBV serum prepared by immunisation with whole purified virus possessed a high neutralising antibody titre[10]. It was not possible to use purified virus as a source for the biochemical characterisation of the antigens recognised by these antibodies because of the technical difficulties involved in concentrating and purifying the small amount of virus released

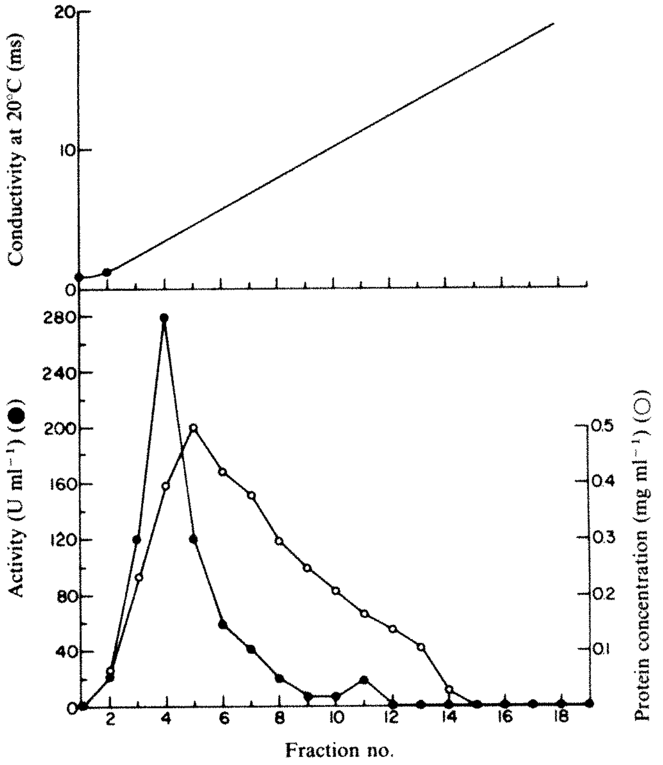

Fig. 1 Fractionation of EBV membrane antigens by DE-52 ion-exchange chromatography. Plasma membranes were prepared essentially as described previously[18] (full details to be published elsewhere). The plasma membranes (20–30 mg of protein from A_{260}/A_{280}) from ~15 g of P3HR-1 cells grown in restrictive conditions were resuspended in 10 mM Tris *p*H 7.4, 0.25 mM dithiothreitol (DTT) and solubilised by the addition of Triton X-100 (3:1 w/w, Triton X-100:protein) for 30 min at 4 °C. The solution was clarified by centrifugation at 200,000 *g* for 1 h and the supernatant applied to a 4 ml column of DE-52 previously equilibrated with 10 mM Tris *p*H 7.4, 0.25 mM DTT and 0.2% Triton X-100. The column was washed with 2–3 column volumes and the bound material eluted with a linear gradient (1 ml fractions, 15 ml h^{-1}) of 0–0.4 M potassium phosphate *p*H 7.4 in the equilibrium buffer. Fractions were all dialysed against phosphate buffered saline (PBS) before assay. Protein (○) was estimated by the method of Lowry[14] and EBV membrane antigens (●) by competition of the ^{125}I-PrA assay (see Fig. 2). Approximately 5.52 mg of protein and 2,600 units of membrane antigen were applied to the column.

Table 1 Effect of adding the neutralising (anti-P3HR-1) and control (anti-RAMOS) antisera at various times pre- and post-infection

		Infectivity assayed by:			
		DNA synthesis† (^{3}H-thymidine incorporation)		Outgrowth‡ (no. of wells with transformed foci)	
Time antibody added*	Addition of virus	Anti-P3HR-1	Anti-RAMOS	Anti-P3HR-1	Anti-RAMOS
1 h pre-infection	+	160	4,900	0/6	6/6
2 h post-infection	+	8,100	9,300	6/6	6/6
24 h post-infection	+	7,900	7,200	6/6	6/6
No antibody added	+	7,400		6/6	
No antibody added	−	100		0/6	

*Antisera were used at a dilution of 1:15.

by producer cell lines. However, the neutralising antibodies could be specifically absorbed by EBV producer cell lines[10]. Therefore, the neutralising antigens are expressed on the plasma membranes of these permanently growing lymphoblastoid cell lines which may be cultured to indefinitely large volumes, thus providing a potential source of large amounts of the antigens. Furthermore, the antigen could be assayed for quantitatively by means of the ^{125}I-labelled *Staphylococcus aureus* protein (^{125}I-PrA) assay[10] and it has been possible to purify and identify components of the membrane antigen using this assay. The antigen comprises a glycoprotein complex of at least three major (molecular weights (MW) 350,000, 140,000 and 75,000) and several minor polypeptides present on the plasma membrane of all producer cell lines[11] and on the virion itself (unpublished results). It was decided, therefore, to try to immunise rabbits specifically against EBV using a partially purified preparation which contained this complex of polypeptides.

Plasma membranes were purified from the P3HR-1 cell line by nitrogen cavitation followed by differential sucrose density centrifugation. The resulting purified plasma membranes contained 4–6% DNA by weight as judged by A_{260}/A_{280} (ref. 12). They were solubilised with the non-ionic detergent Triton X-100 and passed over a DE-52 ion exchange column to remove the residual DNA[13]. The material which bound to the column was eluted with a salt gradient. The fractions were assayed for protein by the method of Lowry as modified by Dulley and Grieve[14] and for EBV-specific membrane antigens by inhibition of the ^{125}I-PrA binding assay[11] (Fig. 1). The tubes with peak activity were pooled, assayed for DNA content[15] and found to have 0.25% DNA by weight compared to Lowry protein (salmon sperm DNA and bovine serum albumin were used as standards).

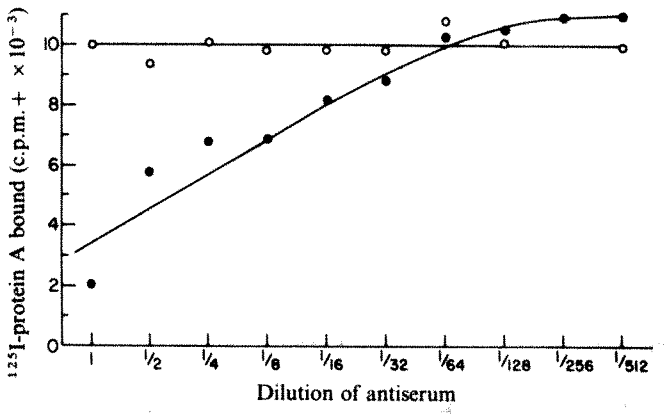

Fig. 2 Assay for the purified (from P3HR-1) and mock-purified (from RAMOS) EBV membrane antigen using competition of the ^{125}I-labelled staphylococcal protein A assay. The appropriately diluted antigen (50 μl) in a final solution of 0.1% Triton X-100 in PBS was incubated overnight with antibody (10 μl of 1:8 diluted rabbit anti-EBV serum) at 4 °C. The antibody activity in duplicate 25 μl aliquots was then assayed as described previously[10] except that the P3HR-1 cells used in the assay were first fixed with glutaraldehyde. The activity in units may be calculated as follows: the dilution of antigen required to inhibit the assay by

$$\frac{\text{total volume of sample } (\mu\text{l})}{50}.$$

In this experiment an antigen dilution of 1 is equivalent to 160 μg per ml of membrane protein. A background of 2,600 c.p.m. obtained with normal rabbit serum has been subtracted from these data. ●, Antigens purified from producer cell line P3HR-1; ○, antigens mock-purified from EBV-negative cell line RAMOS.

A mock purification was performed using the EBV-negative lymphoblastoid cell line RAMOS. The pooled fractions from P3HR-1 and RAMOS were then tested for their ability to compete for the rabbit anti-EBV serum in the ^{125}I-PrA binding assay (Fig. 2). Only the preparation from P3HR-1 was able to compete, indicating that this material contained the specific EBV membrane antigens.

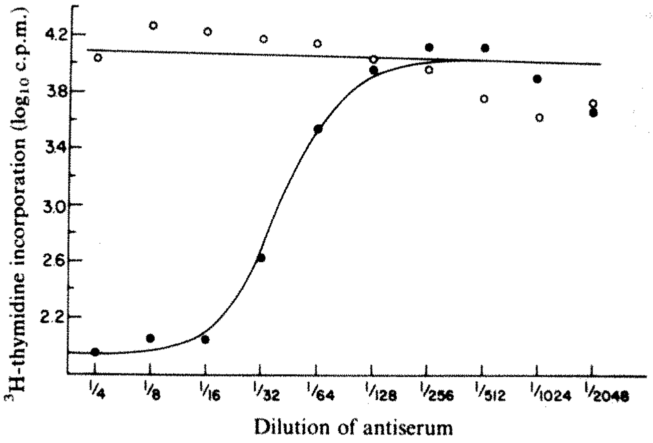

Fig. 3 Neutralisation of EBV infectivity by serum from immunised and mock-immunised rabbits. Infectivity was assayed by measuring the stimulation of DNA synthesis in resting peripheral B lymphocytes. Rabbits were immunised with partially purified antigens from a DE-52 column (Figs 1, 2). The material, consisting of ~100 μg of protein in 0.5 ml of 0.1% Triton X-100 and PBS, was emulsified in complete Freund's adjuvant and inoculated subcutaneously in the neck and intramuscularly in the thigh. The procedure was repeated three times over the course of two months and the animals were bled 10 days after the last injection. Before use in the neutralisation assay sera were absorbed 4 times for 1 h at room temperature with an equal volume of fresh peripheral lymphocytes to remove nonspecific cytotoxic activity from the sera. The methodology for assaying neutralising activity in sera has been described in detail elsewhere[10]. Briefly, the B95–8 strain of virus and sera were incubated for 1 h at 37 °C and then added to fresh B lymphocytes purified from the blood of normal adult humans by immunoabsorbent chromatography. The cells were then incubated for 1 week and proliferation assayed by measuring incorporation of ^{3}H-thymidine. Each experiment was performed in triplicate. ●, Antiserum prepared from a rabbit immunised with partially purified EBV membrane antigens from the EBV producer cell line P3HR-1; ○, antiserum prepared from a rabbit immunised with mock-purified EBV membrane antigens from the EBV-negative cell line RAMOS.

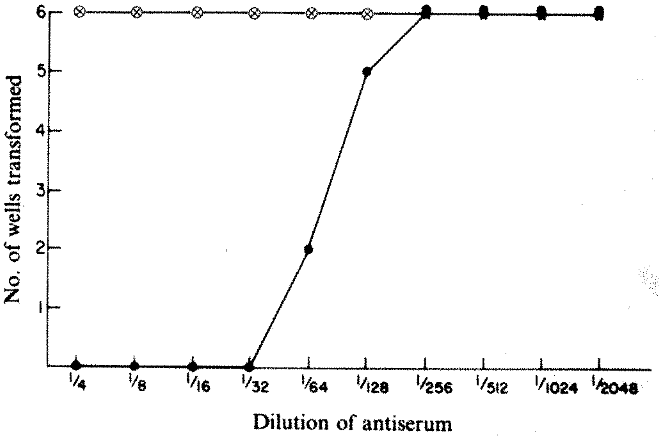

Fig. 4 Neutralisation of EBV infectivity by serum from immunised and mock-immunised rabbits. Infectivity was assayed by measuring the outgrowth of transformed foci. Details as for Fig. 3 legend, except infectivity was assayed by setting up 6 culture wells for each point and counting the number of wells containing transformed foci of proliferating lymphoblasts 20 days postinfection[10]. ●, Antiserum prepared from a rabbit immunised with partially purified EBV membrane antigens from the EBV-producer cell line P3HR-1. ○, Antiserum prepared from a rabbit immunised with mock-purified EBV membrane antigen from the EBV-negative cell line RAMOS. ×, Normal rabbit serum.

Rabbits were immunised with the partially purified material from RAMOS and P3HR-1 and the resulting antisera were tested for their ability to neutralise the virus *in vitro*. EBV from the B95–8 lymphoblastoid cell line was preincubated with the different sera at various dilutions and the mixture was then used to infect peripheral B lymphocytes from normal adult donors. The infectivity was estimated by measuring either the stimulation of cellular DNA synthesis in the B cells (Fig. 3) or the outgrowth of foci of transformed lymphoblasts[16] (Fig. 4). In both experiments the virus infectivity was neutralised by the antiserum (titre 1:50 to 1:100) raised by immunising with the partially purified EBV membrane antigens from P3HR-1. The equivalent serum raised against mock-purified antigens from the RAMOS cell line was completely ineffective, as was preimmune normal rabbit serum. When the antiserum against P3HR-1 was added a few hours postinfection (Table 1), it was completely ineffective in preventing the infection. These results suggest that the antiserum was specifically neutralising the virus and was not toxic for the infected cells.

These results demonstrate that it is possible to generate a specific EBV-neutralising antibody response in experimental animals with a DNA-free preparation of partially purified membrane antigens from the plasma membranes of EBV-producer cell lines. These results are in agreement with previous observations[19] that EBV membrane antigens removed from super-infected RAJI by papain digestion would invoke an EBV-neutralising response. The production of EBV membrane antigens by super-infection will, however, be difficult to scale up. By comparison, the source of membrane antigens in the present study was EBV producer lymphoblastoid cell lines. As these cell lines are permanently established in culture, they provide a potentially limitless source of the EBV membrane antigens. In addition, the culture conditions and purification procedures used were simple and will be amenable to scaling up for production of large amounts of vaccine.

As well as the above mentioned associations with neoplasia in man, EBV has been shown to cause tumours in certain New World monkeys, notably marmosets[17]. This provides further support for the suggested etiological role of EBV in human carcinogenesis. The next test for the immunogen described here will be to assess its ability to immunise these monkeys against EBV-induced neoplasia.

I thank Dr Clark Edson for advice. This work was supported by NIH grant no. 1 RO1 A11 5310–01.

Immunoregulatory effects of a covalent antigen–antibody complex

R. B. Taylor & J. P. Tite

MRC Immunobiology Group, Department of Pathology, The Medical School, University Walk, Bristol, UK

C. Manzo

Division de Immunologia, Fondazione Senatore Pascale, Istituto per lo Studio e la Cura dei Tumori, Capella dei Cangiani, Napoli, Italy

It is becoming increasingly clear that any specific immune response must be subject to a control mechanism of the same order of specificity. The basis of such specificity in control almost certainly lies in the antibodies themselves, whether free or cell bound. The response to a given antigen might then be regulated by antibodies specific either for the antigen ('Ab 1') or for the variable regions (idiotypes) of Ab 1. Whereas the latter can interact directly with the binding sites of cellular receptors for antigen, the former can only do so if the antigen is also present to act as a bridge. Furthermore, because an anti-idiotype antiserum is usually prepared against a monoclonal antibody, it will only be able to influence directly those clones of cells which carry the chosen idiotype, and thus may leave unaffected other clones which are specific for the same antigen but which carry different idiotypes. An immune complex, on the other hand, should influence all clones sensitive to the antigen in question. Experimentally, the injection of antigen–antibody complexes can either increase[1,2] or decrease[3,4] the subsequent response to antigen. These effects often require the presence of an intact Fc region[4] and may differ according to the class (or isotype) of the antibody[5]. The injection of anti-idiotype antisera can have striking effects on the expression of particular idiotypes, but usually has little effect on the overall response. Again, these effects require the participation of the Fc region of the anti-idiotype antibody[6], and can vary according to its isotype[7,8]. To study the regulatory effects of antibody more closely, we have attempted to prepare immune complexes which could influence the overall response, and yet have effects as powerful as those obtained with anti-idiotype antibodies. The immune complexes obtained were of the defined constitution Ag_2Ab, in which stability was ensured by linking antigen to antibody through a covalent bond. We report here that, depending on the conditions used, these complexes induced either priming or tolerance of the response of mice towards subsequent injections of antigen alone. We consider that such complexes could be useful not only as tool for studying immunoregulation, but also as a practical means of influencing immune responses.

The complexes were prepared by mixing hapten–conjugates of the chosen antigen with anti-hapten antibody. Cross-linking was minimised by the use of conjugates which were as far as possible monosubstituted with the hapten. The complexes were rendered stable by the introduction of a covalent bond through the use of the photosensitive affinity label 'NAP' (4-azido-2-nitrophenyl)[9] as the hapten. As the antigen now becomes effectively an extension of the antibody variable region (Fig. 1), such a complex should mimic an anti-idiotype antibody in its mode of interaction with cellular receptors. The method is summarised in Fig. 1 legend and will be reported in detail elsewhere. As antigen we used pancreatic ribonuclease D (RNase; Sigma).

In the first experiment young adult mice of the hybrid strain (BALB/c × CBA/H)F_1 were each injected intravenously with a single dose of either complex containing 0.16–100 μg of complexed anti-NAP, or free RNase equal to that contained in 4 μg or 100 μg complex, or were left uninjected. Six weeks later the mice were each challenged intraperitoneally with 50 μg of RNase in complete Freund's adjuvant. They were bled 2 weeks

0028-0836/79/410488—03$01.00

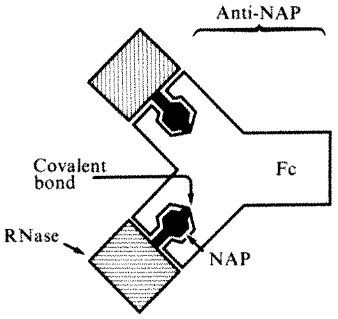

Fig. 1 Diagram of a molecule of covalent complex of NAP-RNase with anti-NAP. NAP was first converted into a form which on the one hand was more reactive with proteins in physiological conditions, and on the other included a spacer chain so as to increase the likelihood of its being sufficiently exposed to interact with the antibody. This was done by reacting NAP with aminocaproic acid in the presence of sodium carbonate, as described by Fleet *et al.*[9] for NAP-lysine. The resulting NAP aminocaproic acid (NAP-cap) was coupled to *N*-hydroxysuccinimide to form the succinimide ester (NAPcapOSu) using dicyclohexylcarbodiimide, as described by Becker and Mäkelä[13] for the analogous DNPcapOSu. The concentration was estimated by optical density after dilution in 0.05 M glycine, *p*H 8.5, assuming E_{M}^{485} = 4,800. An aliquot of NAPcapOSu was stirred rapidly with a 2 molar equivalent of RNase at 10 mg ml^{-1} in 0.05 M HEPES, *p*H 7.5, for 1–2 h at room temperature. Uncombined hapten was removed by passage through a Sephadex G-25 column. As RNase has one lysine side chain which is much more reactive than the others at *p*H values close to neutral[14], it was thought likely that this treatment would result in very few molecules having more than one NAP attached. Anti-NAP antibody was prepared in rabbits by injection of NAPcap–keyhole limpet haemocyanin (9 haptens per 100,000 molecular weight) in complete Freund's adjuvant. It was purified by elution with hapten from an immunoadsorbent column. NAPcap–RNase, prepared with RNase trace labelled with ^{125}I, was mixed with anti-NAP antibody in a 2 molar excess of NAP to the antibody-binding sites, and the mixture was illuminated with a standard 60-W bulb for 15 min. The antibody was then concentrated by precipitation with 50% saturated ammonium sulphate, redissolved in a small volume and passed through a gel-permeation column of AcA 34 (LKB). The radioactivity served to monitor RNase, and optical density at 280 nm was mainly due to anti-NAP. It was found that some of the RNase eluted with the anti-NAP whereas the rest followed in the position expected for free RNase. The concentration of RNase in the pooled first peak was obtained from the radioactivity, and multiplied by the ratio of molecular weights to give the concentration of complex, expressed in terms of complexed anti-NAP.

later and their sera titrated for anti-RNase antibody activity by a modification of Farr's ammonium sulphate procedure[10], using ^{125}I-labelled RNase at 10^{-8}M. The results (Fig. 2) show that whereas RNase alone had little or no priming effect, the activity of the complex was extremely strong. It was detectable at the 0.16 μg dose of complex (containing 0.027 μg RNase) and rose to a maximum at the 20 μg dose. For subsequent experiments 10 μg was chosen as the minimal dose required for optimal effect.

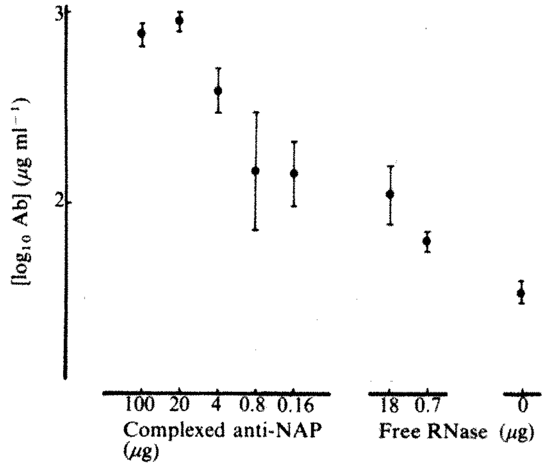

Fig. 2 Dose curve of priming by complex. (BALB/c×CBA/H)F$_1$ mice were injected intravenously with the doses of RNase complex or free RNase as indicated, 6 weeks before challenge with 50 μg RNase in complete Freund's adjuvant. Sera from a day 14 bleed were assayed by the Farr technique. Each group contains six mice.

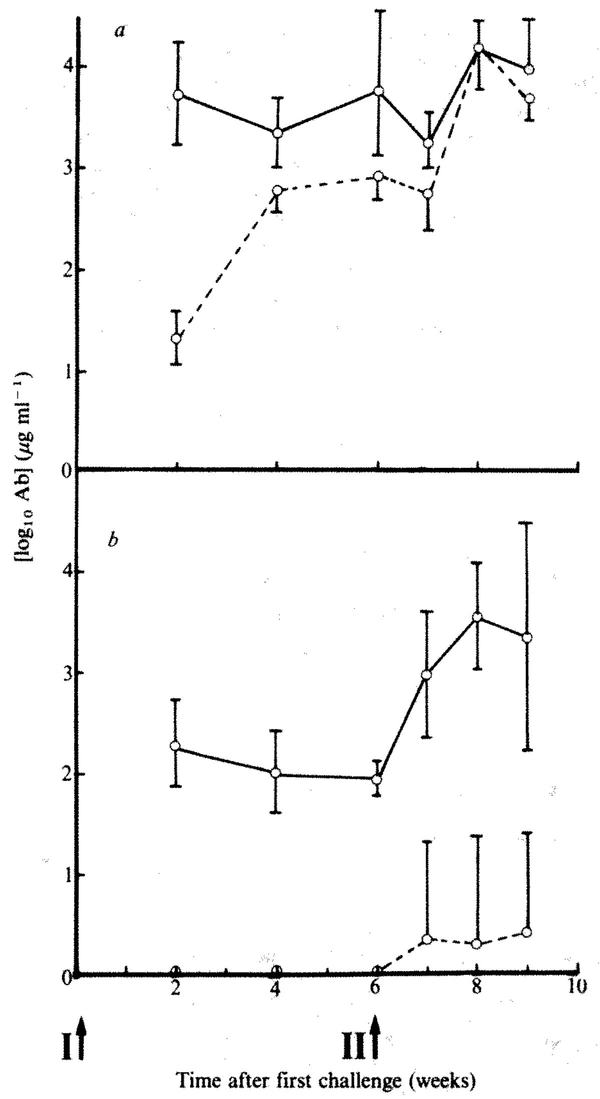

Fig. 3 Challenge with or without adjuvant. Mice were either primed with 10 μg RNase complex (O—O) or left unprimed (O- - - -O). Six weeks later they were challenged with 100 μg RNase (I↑) either in complete Freund's adjuvant (*a*) or in saline (*b*). After a further 6 weeks they received a second challenge (II↑) of 100 μg RNase in incomplete Freund's adjuvant (*a*) or saline (*b*).

The second experiment shows that adjuvant is not necessary to recall the priming induced with covalent immune complex, as this can also be done with soluble antigen. Complex-primed or control mice were challenged with 100 μg RNase in either complete Freund's adjuvant (Fig. 3*a*) or saline (Fig. 3*b*). Although unprimed mice made no detectable antibody in response to the first challenge with soluble RNase, complex-primed mice made over 100 μg ml^{-1}. After a second challenge a few of the controls showed a small response, but the primed mice made about 5 mg ml^{-1} antibody, (over 1,000 times more than controls) and reached about the same level as the maximum achieved by the adjuvant-challenged groups. With adjuvant challenge (Fig. 3*a*) this maximum titre was achieved by the complex-primed group as early as 14 d after the first challenge, and was not increased further by a second challenge. By contrast, the titres of unprimed mice rose much more slowly, although after the second challenge they did eventually match those of the complex-primed mice.

It seemed possible that this remarkable priming effect was dependent on the rabbit antibody being itself a foreign protein. To test this, some mice were made tolerant to rabbit IgG by intraperitoneal injection of 1 mg of an ultracentrifuged preparation of the fraction precipitating between 0.81 and 0.92 M sodium sulphate[11]. One week later they were injected with 10 μg RNase complex as before. Controls received complex alone, equivalent RNase, or no injection. After challenge 6 weeks later with RNase in complete Freund's adjuvant (Fig. 4), the priming effect was again seen in the mice receiving complex alone. By contrast, the mice which had previously been made tolerant to rabbit IgG showed a marked suppression of the response to RNase. Both the priming and suppressive effects were still present, although somewhat diminished, 10 weeks after the first challenge, but were almost abolished after a second challenge.

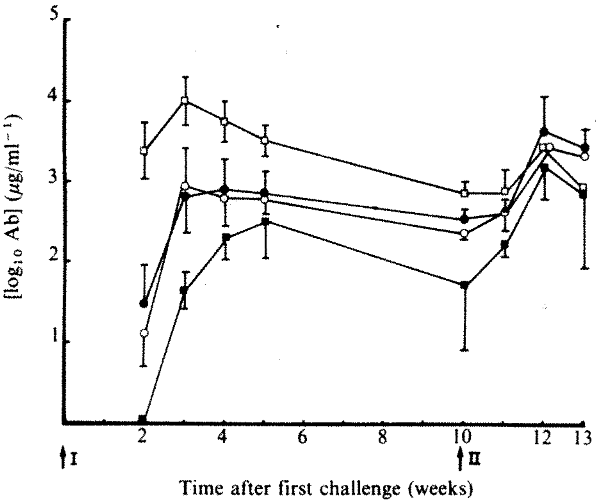

Fig. 4 Effect of prior tolerance to rabbit IgG. One group of mice was injected with 1 mg of rabbit IgG, prepared as described in the text (■), and the other three groups were left uninjected. One week later the four groups received 10 μg RNase complex (□, ■), 2 μg RNase (●), or no injection (○). All groups were challenged twice, at 6 and 16 weeks later, with 100 μg RNase. The first challenge was with complete (I↑) and the second with incomplete (II↑) Freund's adjuvant.

The results described here demonstrate that powerful immunoregulatory effects can be obtained with a covalent antigen–antibody complex. Because rabbit antibody was used in these experiments, it was first expected that the complexes would suppress the response to RNase, by analogy with the suppressive effect of injecting rabbit antibody to a mouse idiotype[12]. However, there are several differences between these two situations which may be significant. One of these is the fact that, whereas the complex was prepared from purified antibody, the anti-idiotype was administered as a whole immunoglobulin fraction, and thus would have contained nonspecific immunoglobulin in considerable excess to the anti-idiotype antibody. This might have had the same effect as the prior injection of rabbit IgG in our experiment. However, our unpublished experiments using anti-NAPs prepared in various species indicate that the recognition of foreign epitopes on the immunoglobulin is by no means the only factor which determines whether the outcome of injecting such covalent complexes is one of priming or suppression. For example, priming effects have been obtained with complexes formed from an IgG1 fraction of isologous mouse anti-NAP.

We have also studied the mechanism of action of the rabbit anti-NAP–NAP–RNase complex, and found that the Fc portion of the molecule is essential for its immunoregulatory effects, and that covalent bonding greatly enhances these effects, but is not essential for them; these studies will be reported elsewhere. We have obtained equally strong priming effects with several antigens other than RNase, suggesting that this may possibly represent a practical immunisation schedule which could have particular value in that it completely avoids the use of adjuvants.

Graft-versus-leukaemia reactivity induced by alloimmunisation without augmentation of graft-versus-host reactivity

Supralethal doses of chemoradiotherapy followed by allogeneic bone marrow transplantation are being used to treat patients with acute leukaemia refractory to conventional chemotherapy regimens[1-5]. Despite this approach, leukaemia has recurred in about one-third of the patients[1-5]. One strategy to solve this problem would be to transplant marrow with antileukaemic reactivity to obtain a graft-versus-leukaemia (GvL) effect against residual leukaemia cells[6]. Many workers have demonstrated antileukaemic effects following transplantation of immunocompetent cells from allogeneic donors in animal models, but graft-versus-host (GvH) disease proved to be a complication[6-8]. Recently, Weiden *et al.*[9] presented evidence of a GvL effect in human recipients of marrow grafts from HLA compatible allogeneic donors. Unfortunately, this antileukaemic effect was associated with moderate, severe or lethal GvH disease, and the lower probability of recurrent leukaemia was offset by a higher probability of GvH-related mortality[9]. We report here the results that suggest a clinically feasible method of obtaining desired GvL effects while avoiding undesired GvH reactions. Alloimmunisation of CBA (H-2^{k}) mice was found to induce a population of cells which, when transplanted into leukaemic AKR (H-2^{k}) mice, led to the destruction of disseminated leukaemia (AKR-L) cells. Furthermore, the transplanted cells caused no augmentation in the mild GvH disease observed when cells from unimmunised CBA donors were administered to lethally irradiated non-leukaemic AKR hosts.

Immunocompetent cells from CBA mice were tested for GvL reactivity in a bioassay system as follows: On day zero, 1×10^5 viable AKR-L cells (obtained by pooling fresh spleen cells from 15 AKR mice bearing spontaneous T cell acute lymphoblastic leukaemia) were inoculated intravenously (i.v.) into lethally

0028–0836/79/410491—02$01.00

irradiated (800 rad, total body 4h previous) 8–12-week-old AKR primary hosts. One day later, as the sole antileukaemic treatment, immunocompetent cells (2×10^7 spleen or 10^7 bone marrow plus 10^7 lymph node) from unimmunised, isoimmunised, specifically immunised or alloimmunised CBA donors were transplanted into the AKR primary hosts. The GvL reaction was allowed to proceed for 6 d. To determine whether any viable leukaemia cells remained all spleen cells from each AKR primary host were transferred intraperitoneally (i.p.) to an individual 8–9-week-old AKR secondary recipient on day 7. Using this protocol all but one of 427 control animals, that is, those not given cells from immunised donors, died of leukaemia by day 53. Thus, the proportion of mice alive on day 90 provided a rigorous test of the GvL reactivity of immunised CBA cells.

To evaluate GvH reactivity, 8–12-week-old non-leukaemic AKR mice were exposed to 800 rad total body irradiation and given i.v. injections of immunocompetent cells from unimmunised or immunised CBA donors. The AKR hosts were observed daily for clinical evidence of GvH disease; all deaths were attributed to GvH disease.

The results are shown in Table 1. No antileukaemic effect was observed if AKR primary hosts were given no treatment (group 1) or cells from unimmunised or isoimmunised CBA donors (groups 2 and 3). Cells from specifically immunised CBA donors (group 4) had significantly greater GvL reactivity ($P < 0.001$) than did cells from isoimmunised CBA mice (group 3). Significant GvL reactivity ($P < 0.01$) was induced in CBA donors following immunisation with DBA/1 cells (group 5) in comparison with unprimed CBA cells (group 2); although the difference in GvL reactivity was not significant in comparison with group 3, this may have been due to the small group sizes. Immunisation of CBA donors with lymphoid cells from the other six H–2 incompatible strains of mice (groups 6–11) in each instance induced significant GvL reactivity ($P < 0.001$) in comparison with group 3, as did either six or two immunisations of CBA donors with pooled lymphoid cells from the seven H–2 incompatible strains (groups 12, 13).

Table 1 Survival data from assays in which immunocompetent cells from CBA (H–2^k) donor mice were tested for GvL reactivity in leukaemic AKR (H–2^k) mice and for GvH reactivity in nonleukaemic AKR mice

Group	Donor of transplanted cells*	GvL reactivity of donor cells† No. alive at 90 d/ no. AKR mice transplanted (%)	GvH reactivity of donor cells No. alive at 90 d/ no. AKR mice transplanted (%)
1	None	1/308 (0)	3/155 (2)
2	CBA	0/108 (0)	52/77 (68)

12	CBA α Pool × 6	12/12 (100)	10/12 (83)
13	CBA α Pool × 2	11/12 (92)	11/12 (92)

Irradiated (800 rad) leukaemic and nonleukaemic AKR hosts received 2×10^7 spleen or 10^7 bone marrow plus 10^7 lymph node cells i.v. from unimmunised (group 2), isoimmunised (group 3), specifically immunised (group 4) or alloimmunised (groups 5–13) CBA donors. χ^2 test was used for significant differences between groups.

* CBA donors received six weekly immunisations i.p. with 1×10^7 lymphoid cells from the indicated strains; the H–2 haplotype of the immunising strain is in parentheses. AKR leukaemia cells (group 4) were irradiated with 3,000 rad. For pool immunisation (groups 12 and 13), 1×10^7 lymphoid cells from each of the seven H–2-incompatible strains were combined and injected i.p.; mice in group 13 received only two immunisations. CBA mice were used as donors one week after the last immunisation.

† A bioassay system was used to measure the GvL reactivity of CBA donor cells. All deaths were due to leukaemia.

The theoretical and experimental bases for the GvL bioassay model and the rationale for the use of the spleen as the most sensitive bioassay organ have been described previously[10]. This bioassay allowed critical evaluation of GvL reactivity without the potentially confounding complications of radiation injury, failure to obtain engraftment and GvH disease. All of these complications, in addition to leukaemia, could have been the cause of death had the primary rather than the secondary recipient been evaluated for survival and autopsied at the time of death.

T lymphocytes appeared to be required for the GvL reaction. Rabbit anti-θ serum and complement treatment of spleen cells from CBA mice alloimmunised with SJL lymphoid cells abolished GvL reactivity (none of 11 mice survived 90 d), whereas treatment of these cells with normal rabbit serum and complement caused no diminution of GvL reactivity (7 of 10 mice survived 90 d). This observation does not exclude a role for natural killer (NK) cells, as it has been suggested that NK cells express low density thy-1 antigen[11] and that alloimmunisation augments NK activity[12].

Survival data from GvH assays are presented in Table 1. Cells from specifically immunised CBA mice (group 4) caused a significant increase in GvH-related mortality in comparison with cells from unimmunised (group 2) CBA donors ($P < 0.005$) or isoimmunised (group 3) CBA donors ($P < 0.001$). However, transplanted cells from alloimmunised CBA mice (groups 5–13) caused no significant increase in mortality in comparison with groups 2 or 3.

Bach *et al.*[13] first proposed pool-priming as a means of generating cytotoxic cells to tumour or virus-infected targets. Zarling *et al.*[14] subsequently demonstrated that lymphocytes sensitised *in vitro* to pooled allogeneic cells were cytotoxic to autologous human leukaemia cells *in vitro*. The findings reported here extend these observations by demonstrating that pool-alloimmunisation *in vivo* generated cells which, when transplanted, killed disseminated AKR-L cells *in vivo*.

Several possibilities exist to explain the effectiveness of alloimmunisation in the induction of GvL reactivity. Activation of T cells which help antigen-specific or nonspecific reactions against the leukaemia targets, activation of NK cells and/or sensitisation of cytotoxic T lymphocytes to alloantigens cross-reactive with leukaemia target antigens are all possibilities. Whatever the mechanism, immunisation of CBA mice with allogeneic H-2-incompatible cells induced GvL reactivity without augmenting the GvH response. To the extent that sensitisation to antigens on cells of a single allogeneic strain in some cases led to relatively weak GvL reactivity, pool-alloimmunisation may circumvent the need to understand which alloantigens are needed to induce the desired GvL effect.

This investigation was supported by NCI grants CA 20484 and CA 18440 and grants from the Leukemia Research Foundation and the Briggs and Stratton Corporation Foundation. Evangeline Reynolds, Eli Godfried, Lisa Lavery, Patricia Matthew and Shirley Stanko provided technical assistance.

Complement-fixing IgG1 constitutes a new subclass of mouse IgG

Peter L. Ey*, Stephen J. Prowse & Charles R. Jenkin

Department of Microbiology and Immunology, The University of Adelaide, PO Box 498, Adelaide, 5001 South Australia

Four IgG isotypes (IgG1, IgG2a, IgG2b, IgG3) have been distinguished in the mouse[1-3]. The similarity of the physicochemical properties of the different isotypes has to a large extent prevented their purification from serum and this has complicated functional studies on IgG antibodies in sera from infected or immunised mice[1,2,4]. The availability of immunoglobulin-secreting plasmacytomas[5], however, has made the production of isotype-specific antisera possible; the use of these antisera has shown immunoglobulin of each isotype to exist in sera from normal animals[3,5,6]. IgG1 antibodies, partially separated from IgG2 by electrophoresis in agar, have been reported[2] to be incapable of sensitising sheep red blood cells (SRBC), passively coated with antigen, for lysis by complement (C) although the antibodies agglutinated the cells and also mediated passive cutaneous anaphylactic (PCA) reactions in the mouse. The IgG2 antibodies, which mediated PCA reactions in the guinea pig but not in the mouse, lysed the antigen-coated SRBC in the presence of mouse C. It seems on the basis of this single report that mouse IgG1 has been widely accepted[6-8] to be a 'non-C-fixing' class of immunoglobulin—one which, on association with antigen, is unable to activate C. We have now purified IgG1 from the serum of mice immunised with SRBC and in this report present evidence that the IgG1 antibodies are not only haemolytic in the presence of C, but that they apparently account for more than half of the SRBC-specific, C-fixing IgG antibodies in the serum of the immunised animals.

Six-week-old female LACA mice from a random-bred specific-pathogen-free colony were conventionalised for 3 weeks before being injected intravenously with 1×10^8 SRBC in 0.2 ml of saline on days 0 and 21. Blood was collected on day 32, pooled and the serum stored at −20 °C. IgG1, IgG2a and IgG2b immunoglobulin was purified from the serum by fractionation on protein A-Sepharose CL-4B (Pharmacia) as previously described[9]. The peak eluate fractions were pooled, dialysed against 0.15 M NaCl–15 mM NaN_3 and stored at 4 °C to minimise aggregation.

Each IgG preparation was titrated for SRBC-specific antibodies by haemagglutination as well as by C-dependent haemolysis. The haemolytic titrations (Fig. 1) showed that each preparation contained antibodies which were lytic for SRBC in the presence of guinea pig C. This activity was SRBC specific, since neither agglutination nor lysis was observed when human or guinea pig RBC were used as target cells and the activity could be removed by adsorption to SRBC but not to the other types of cells (data not shown). Because IgG1 antibodies were believed to be incapable of activating C (ref. 2), it was thought possible that the IgG1 preparation contained trace amounts of SRBC-specific IgM antibody or aggregated IgG1 which might bind to the cells and activate C nonspecifically, perhaps via the alternative pathway. Thus, all of the IgG1 immunoglobulin was chromatographed on Sephadex G-200 to separate IgM and aggregated IgG from unaggregated (monomeric) IgG molecules. As depicted in Fig. 2, this fractionation yielded a single, homogeneous peak of monomeric IgG1 which represented, within the limits of detection, all the protein applied to the column. All the detectable haemolytic and haemagglutinating antibody activity was associated with this monomeric IgG1 protein peak. The fractions representing the void volume, where IgM and aggregated IgG would be expected to elute, contained neither agglutinating nor haemolytic activity. The IgG1 haemolytic activity was therefore not due to 19S IgM antibody, to aggregated IgG1, or to monomeric (8S) IgM (an unlikely possibility) since the latter would have eluted with the leading edge of the IgG peak (the same column has been used successfully to resolve IgE and IgG1 antibodies, measured by PCA reactions[10]). Subsequent chromatography of samples of the IgG2a and (separately) the IgG2b indicated that these preparations similarly consisted of only monomeric IgG.

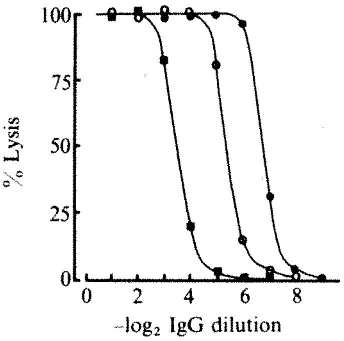

Fig. 1 Titration of IgG1, IgG2a and IgG2b for capacity to lyse SRBC in the presence of guinea pig C. All reagents were diluted in Veronal-buffered saline (*p*H 7.4) containing 0.15 mM $CaCl_2$ and 0.5 mM $MgCl_2$ (VB^{2+})[18], supplemented with 0.2 mg ml^{-1} bovine serum albumin and 7.5 mM NaN_3 (VB^{2+} − BSA). Fresh guinea pig serum, absorbed with SRBC (3 ml packed cells per 30 ml serum; 30 min, 0 °C). was stored at −20 °C in 0.25-ml aliquots which were thawed as required at room temperature and used immediately. Two-fold serial dilutions of antibody (0.2 ml) were mixed with 0.4 ml of 0.5% SRBC (3×10^7 cells) with rapid mixing. After incubation at 37 °C for 30 min, 0.2 ml of a 1 : 20 dilution of guinea pig serum was added. The tubes were incubated for 60 min at 37 °C, immediately centrifuged and the absorbance at 541 nm determined for each supernatant. Lysis is expressed relative to water-lysed (100%) and SRBC+C (0%) controls. No lysis of antibody-sensitised SRBC was observed in the absence of C. ●, IgG1; ○, IgG2a; ■, IgG2b.

Table 1 SRBC-specific antibody activity of IgG preparations

IgG*	Haemagglutination†	Haemolysis‡
IgG1	1/174	1/82.8 (1/146)
IgG2a	1/36	1/73.0 (1/93.6)
IgG2b	1/<1	1/12.8 (1/70.7)

* Analysis (μg per ml; protein, IgG1, IgG2a, IgG2b, IgM). IgG1: 568, 502, <1, <0.4, <0.08; IgG2a: 780, 5.7, 514, 1.24, 0.38; IgG2b: 181, 3.5, 8.08, 210, 0.79; Unfractionated serum: –, 2,580, 2,770, 930, 333. Protein concentrations estimated from A_{280} ($E_{1\%} = 14$), immunoglobulin levels by radioimmunoassay[9,16].

† Twofold serial dilutions of antibody (0.2 ml) in VB^{2+}–BSA (see Fig. 1 legend) mixed with SRBC (0.2 ml, 1%). Endpoint chosen as the maximum dilution causing agglutination, taken to a fraction (1/4, 1/2, 3/4, 1) ($\log_2$) of last positive well.

‡ Dilution of antibody causing 50% lysis using 1 : 20 C. Endpoints were determined by regression analysis of von Krogh plots[18]. Values in parentheses are the specific haemolytic titres calculated for a 1 mg ml^{-1} solution of each IgG.

To determine the purity of the IgG preparations, each was analysed by radioimmunoassay for immunoglobulin content. The IgG1 used for this analysis and for subsequent experiments was recovered from fractions 38–40 of the Sephadex G-200 fractionation (Fig. 2), corresponding to the top of the eluant IgG1 peak. The results of the analyses (Table 1 legend) showed that the IgG2a and IgG2b contained only minor amounts of other immunoglobulins totalling 0.94% and 6.8% by weight respectively. No contaminating immunoglobulin could be

0028-0836/79/410492—02$01.00

detected in the IgG1 preparation (IgM, IgG2a and IgG2b, together <0.26% by weight). The analyses corresponded closely to the protein concentrations, indicating little or no contamination by other serum proteins. This was confirmed by electrophoresis of each IgG (labelled with ^{125}I) on SDS-polyacrylamide gels[11] (not shown). In non-reducing conditions, the radioactivity migrated as a single band with a mobility characteristic of intact IgG. After reduction, each sample yielded only two peaks corresponding in mobility to heavy (γ) and light (L) chains. The L chain peak contained 24–28% of the total radioactivity (theoretically, 30%).

The SRBC-specific antibody titres of the IgG preparations are shown in Table 1. Most of the antibody, haemagglutinating and haemolytic, was associated with the IgG1. The specific haemolytic activities, shown in Table 1 in parentheses, indicated that on a weight basis the IgG1 possessed 1.56 and 2.06 times more haemolytic antibody than the IgG2a and IgG2b respectively. The lytic activity associated with the IgG1 could not therefore have been due to contaminating IgG2a or IgG2b, both of which were undetectable. From the concentrations of IgG1, IgG2a and IgG2b in the original serum pool (measured by radioimmunoassay; Table 1 legend) and the calculated specific haemolytic activity of each of the three IgG isotypes, it can be estimated that of the total SRBC-specific haemolytic IgG antibody present in the serum, 54% was due to IgG1, 37% to IgG2a and 9% to IgG2b. The validity of this calculation is conditional on the specific haemolytic activities of the IgG isotypes being unaltered by the purification procedure. The possibility of partial denaturation in the conditions used for elution from the protein A-Sepharose (IgG1, *p*H 5.8; IgG2a, *p*H 4.5; IgG2b, *p*H 3.5) cannot be excluded, although the fractionation was carried out at 4 °C and the fractions were neutralised as they were collected. The observed haemolytic activity of the IgG fraction of the mouse antiserum (isolated by passage of the serum through Sephadex G-200) could, however, be fully accounted for by its content of each IgG isotype (determined by radioimmunoassay) using the specific haemolytic activities calculated above.

As the IgG1 was unaggregated, activation of C by the alternative pathway seemed unlikely. To assess whether the observed haemolysis resulted from activation of C by the classical pathway, the effect of EDTA or EGTA on lysis by each type of IgG was determined. EGTA blocks classical pathway activation but has little effect on the alternative pathway, whereas EDTA inhibits both routes[12]. The results (Table 2) demonstrate clearly that haemolysis by each IgG isotype was mediated entirely by classical pathway activation. Similar results, including those for IgG1, were obtained when normal mouse serum rather than guinea pig serum was used as the source of C.

These findings are apparently in conflict with present opinion[2,6–8] that mouse IgG1 is a 'non-C-fixing' class of immunoglobulin. In other experiments[13], however, we have isolated IgG1 from the sera of mice immunised with several different antigens and have shown that, in certain instances, IgG1 antibodies are unable to fix C and can effectively block lysis of target cells by C-fixing antibodies through competition for antigenic sites on the target cell surface. Since both types of IgG1 antibody can be produced by inbred strains of mice[14], the genes coding for each type of γ chain cannot be allelic. The C-fixing IgG1 therefore seems to represent a previously undescribed mouse immunoglobulin isotype. We propose that the 'non-C-fixing' and C-fixing IgG1 be termed IgG1a and IgG1b respectively, according to the nomenclature for mouse IgG isotypes based on Fahey *et al.*[1,6]. Whether these functionally distinct types of IgG1 correspond to the two antigenically distinct IgG1 myeloma proteins described by Stanislawski and Mitard[15] remains to be shown.

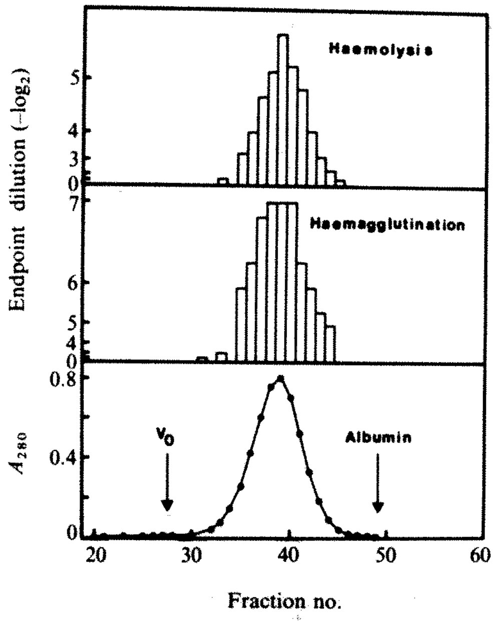

Fig. 2 Sephadex G-200 chromatography of purified IgG1 immunoglobulin. Column size: 2.2×90 cm; sample: 4.1 ml (14.4 mg IgG1); eluant: phosphate-buffered saline (*p*H 7.4) containing 7.5 mM NaN$_3$; flow rate: 15.3 ml h^{-1}. Each fraction (4.1 ml) was assayed for protein (A_{280}) and for SRBC haemagglutinating and haemolytic antibody. A trace of ^{125}I-labelled BSA was added to the sample as an intrinsic marker. The elution positions of albumin and of excluded macromolecules (V_0), determined separately using Blue Dextran 2000 (Pharmacia), are indicated.

Table 2 Haemolytic activity of IgG antibodies in the presence of EGTA or EDTA (% lysis)

Sensitising agent	Control	EGTA	EDTA
IgG1	96.0	2.7	3.7
IgG2a	95.1	3.1	3.5
IgG2b	94.5	4.1	3.3
Inulin	65.2	48.0	2.9

Each tube contained four 50% lytic units of IgG or 5 mg of inulin (Merck). Inulin activates C by the alternative pathway, mediating 'bystander cell lysis' (ref. 17), and was included as a control for alternative pathway activation. The assay diluent was VB^{2+}–BSA with EGTA or EDTA (final concentration, 10 mM) added as indicated. The assay was as described in Fig. 1 except 0.2 ml of guinea pig serum (diluted 1 : 2 in the appropriate diluent) was used. The values shown are the average of triplicate tubes.

We thank Mr G. Ekserdjian for technical assistance and Mrs C. Heanes for typing the manuscript. This work was supported by a grant from the National Health and Medical Research Council of Australia.

Removal of ambient K^+ inhibits net Na^+ transport in toad bladder by reducing Na^+ permeability of the luminal border

Herbert S. Chase Jr & Qais Al-Awqati

Departments of Medicine and Physiology, Columbia University College of Physicians & Surgeons, New York, New York 10032

Sodium crosses epithelia in two steps: an influx into the cell through the luminal membrane down an electrochemical gradient, and an energy-requiring efflux across the serosal border against a gradient. Koefoed-Johnsen and Ussing[1] originally proposed that cellular efflux of Na^+ at the serosal border of frog skin is coupled to K^+ influx by an exchange pump. It was, therefore, assumed that the inhibition of active Na^+ transport following the removal of K^+ from the serosal side was due to a reduced pool of K^+ available for the coupled exchange. Indirect evidence suggests that this is not correct. (1) K^+ influx from the serosa does not correlate to any significant degree with active Na^+ transport[2–5]. (2) Removal of Na^+ as well as K^+ from the serosal medium substantially reduces the inhibitory effect of K^+ removal on active transport[2,6]. (3) One would predict that if K^+ removal did inhibit active transport only at the serosal pump site, then as active transport decreased the 'active transport pool', that is, the mucosally derived cell Na^+, would increase as it does with ouabain. Studies by Robinson and Macknight[7], however, showed that the mucosally derived pool does not change on removal of external K^+. Essig and Leaf[2] suggested that removal of serosal K^+ inhibited Na^+ transport by decreasing the permeability of the luminal membrane. They showed that when K^+ was removed from the serosa, there was a decrease in the amount of ^{22}Na taken up into the tissue after exposure of the luminal surface to the isotope for 5 min. We have recently found that tissue uptake of ^{22}Na after exposure of toad bladders to the isotope is linear with time for only up to 24 s. Because only the linear portion of the uptake is a measure of the Na^+ flux across the luminal border[8], it is clear that longer periods of uptake are more representative of the steady-state isotope distribution in the tissue. This value is controlled not only by the luminal permeability but also by the serosal permeability and the rate of net transport. These issues prompted us to re-investigate the effect of low external K^+ on Na^+ movement across the luminal border. We report here that the Na^+ transport inhibition seems to be due to a reduced Na^+ permeability at the luminal border.

Toad bladders were exposed to ^{22}Na on the mucosal side for 15 s using Thompson and Dawson's modification[9] of the method of Biber and Curran[10]. The uptake, corrected for extracellular contamination (we shall call this the influx) is determined by two factors, the permeability of the luminal border to Na^+ and the electrical driving force across that membrane.

The Na^+ influx was identical to the simultaneously measured rate of net Na^+ transport evaluated as the short circuit current (Table 1). That the influx is actually a measure of Na^+ movement across the luminal border rather than a measure of Na^+ transport across the whole tissue is seen in experiments using amiloride and ouabain. Although these agents reduced net Na^+ transport equally they affected the influx differently. Amiloride, acting on the mucosal side, abolished tranport and influx. Ouabain, however, inhibited net Na^+ transport by 90% but reduced influx by only 40%.

When K^+ was removed from the serosal side the short-circuit current declined to 50% of its initial value in 20 min. Measurement of the influx at that time revealed that it was reduced by an equivalent amount (Table 1 and Fig. 1). As the influx is the product of the Na^+ permeability of the apical membrane and the electrical driving force across that membrane, the cause of the decrease could be due to either factor. Recent studies by deLong and Civan[5], however, have shown that removal of K^+ had no effect on the cell potential in toad bladder. Further, as can be seen in Fig. 1, the influx, in some instances, was reduced to near-zero levels, suggesting that if the only cause for the reduction was a change in the potential, the intracellular voltage must have attained a very large positive value. These considerations suggest that the permeability of the luminal border decreased to cause a reduction in the influx and consequently the short-circuit current.

The identity between influx and short circuit current indicates that the reduction in net transport is due to a reduced Na^+ entry

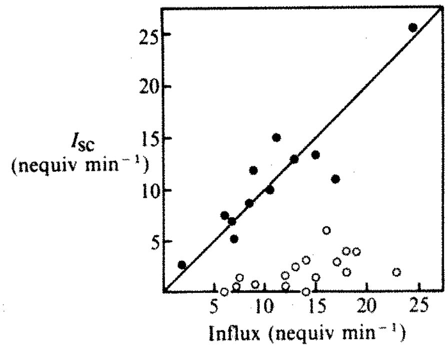

Fig. 1 Plot of the simultaneously measured short circuit current (I_{sc}) with respect to the influx (J) after 20 min of either ouabain (1.0 mM, ○) or K^+-free (●) inhibition. The solid line represents the identity between the short circuit current and the influx obtained in control bladders. The line describing the K^+-free points is $I_{sc} = 0.86\ (\pm0.14)J + 1.5$ nequiv. min^{-1} ($r = 0.89$) and that of the ouabain points is $I_{sc} = 0.22\ (\pm0.08)J - 0.79$ nequiv. min^{-1} ($r = 0.60$). Mucosal Na^+ concentration was 12 mM in all experiments.

Table 1 Effect of ouabain and K^+-free serosal solution on short circuit current and influx

Serosal solution changed to	Initial I_{sc} (nequiv. min^{-1})	Following serosal change I_{sc}	Following serosal change Influx
Ringer's (control)	19.5	21.3	20.6
($n = 9$)	±2.1	±2.8	±3.1
Ouabain (1.0 mM)	24.0	2.2	14.0
($n = 16$)	±1.6	±0.4	±1.2
K^+-Free	22.9	11.0	10.9
($n = 12$)	±1.6	±1.7	±1.8
	Initial I_{sc}	Amiloride I_{sc}	Amiloride Influx
Ringer's	21.1	0	0.1
($n = 4$)	±1.9		±0.1
Ouabain	20.4	0	−0.2
($n = 4$)	±0.9		±0.3
K^+-Free	19.1	0	0.1
($n = 3$)	±7.9		±0.2

In the above experiments small pieces of toad bladder (1.5 cm^2) were mounted in modified Ussing chambers and short-circuited until the current reached a steady value (initial I_{sc}). For all experiments the mucosal solution consisted of (in mM) NaCl 10, $NaHCO_3$ 2.5, KCl 3.5, $CaCl_2$ 1.0 and choline chloride 100. The serosal buffer contained NaCl 110, $NaHCO_3$ 2.5, KCl 3.5 and $CaCl_2$ 1.0. The KCl was omitted without substitution in the K^+-free studies. After the I_{sc} had reached a steady level the serosal solutions were changed. Twenty minutes later the I_{sc} was recorded while the ^{22}Na uptake was being studied. For the control bladders the slope of the influx as a function of short circuit current was 0.95 ± 0.24, intercept 0.5 ± 5.6 nequiv. min^{-1}, $r = 0.83$. In a larger series of control bladders ($n = 20$), influx $= 0.97(\pm0.14) + 0.03(\pm1.10)$ nequiv. min^{-1}, $r = 0.86$. In a separate experiment amiloride (0.1 mM) was added to the mucosa 20 min after the same serosal changes made in the previous experiment.

into the cell. However, these results do not rule out other effects of K^+-free media on the Na^+ pump. Figure 2 shows that the inhibition of the luminal permeability is the major cause of the reduction in net transport. Amphotericin B, when added to the mucosal medium, induces channels in the luminal membrane which accelerate Na^+ entry into the cell[11]. When removal of external K^+ reduced the short circuit current to 30% of its initial value, mucosal addition of 15 $\mu g\,ml^{-1}$ of amphotericin B increased the short circuit current, restoring it to near the initial rate. Ouabain completely inhibited this new current, indicating the current was due to the activity of the Na^+ pump. These results show that the inhibition of net transport by removal of external K^+ was due largely to the reduction of the luminal permeability to Na^+.

As the Na^+ pump is probably the $(Na^+ + K^+)$ATPase, it is rather puzzling that amphotericin enhanced net transport in the absence of external K^+. The most probable explanation is that, although there is no K^+ in the bulk solution, it is unlikely that the K^+ concentration in the unstirred layer next to the serosal border is actually zero. Hence, the pump may still be operating in the Na^+,K^+ mode. Alternatively, it may be exchanging Na^+ for Na^+ in an 'electrogenic' manner.

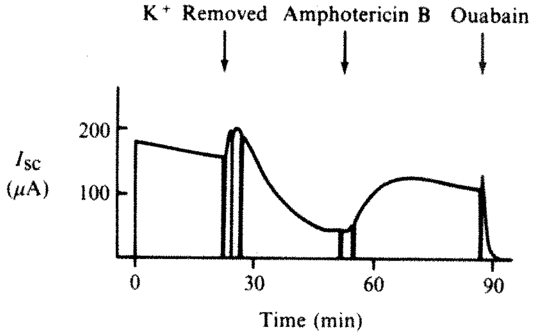

Fig. 2 The tracing obtained from a toad hemibladder mounted in a standard Ussing chamber. As marked, after an initial period during which the bladder reached a steady value, the serosal K^+ was removed (the solution was changed three times). After 20 min, when the current had fallen to ~30% of the initial value, amphotericin B (15 $\mu g\,ml^{-1}$) was added to the mucosal side. Thirty minutes later ouabain (1 mM) was added to the serosal bath in the presence of mucosal amphotericin. The average values of the seven experiments carried out were (in μA): initial I_{sc}, 175 ± 24; 20 min after serosal K^+ removal, 68 ± 13; peak response to amphotericin, 129 ± 19; after ouabain, 0. The mucosal Na^+ concentration was 12 mM.

When serosal K^+ is removed the cells lose K^+ and gain Na^+ concomitantly with the decline in Na^+ transport[2,7]. Removal of serosal Na^+ and K^+ prevents the changes in cell ionic composition and the fall in active transport. These data suggest that changes in intracellular ionic composition are the cause of the reduced permeability of the luminal membrane. The increase in cell Na^+ concentration could reduce the permeability of the Na^+ channels by an allosteric mechanism similar to that invoked by Lindemann[12] and Cuthbert[13] to explain the effect of external Na^+ concentration on the Na^+ permeability of the luminal membrane. Alternatively, an increase in cell Na^+ might increase cytosolic Ca^{2+} (ref. 14) through $Na^+:Ca^{2+}$ exchange across cell and mitochondrial membranes. As with Na^+, external Ca^{2+} has been shown to reduce the Na^+ permeability of the apical membrane[15]. Whether any of these or other mechanisms are involved must be determined by future studies.

Direct addition of insulin inhibits a high affinity Ca^{2+}-ATPase in isolated adipocyte plasma membranes

Harrihar A. Pershadsingh & Jay M. McDonald

Division of Laboratory Medicine, Departments of Pathology and Medicine, Washington University School of Medicine and Barnes Hospital, St Louis, Missouri 63110

The mechanism by which insulin regulates cellular metabolism remains unknown although indirect evidence suggests that alterations in intracellular calcium are important. More specifically, it has been proposed that insulin triggers an increase in intracellular calcium which is responsible for the subsequent modification of metabolic activities[1,2]. The cell maintains a large electrochemical gradient for ionised calcium between the cytoplasm ($<10^{-6}$ M, as determined for muscle[3] and nerve[4]) and the extracellular environment ($>10^{-3}$ M). The plasma membrane may, therefore, be important in the regulation of calcium homeostasis, as a slight alteration in the processes maintaining this gradient could result in marked changes in cytoplasmic calcium. One such process is the active extrusion of calcium from the cell by a high affinity calcium-stimulated ATPase (Ca^{2+}-ATPase). Such a mechanism has been well established in red cells [5] and is postulated in nerve[6], liver[7] and muscle[8]. We have identified a high affinity Ca^{2+}-ATPase in a plasma membrane-enriched subcellular fraction isolated from rat adipocytes[9] which may provide the enzymatic basis for a calcium extrusion pump. We demonstrate here that the Ca^{2+}-ATPase is specifically inhibited by the direct addition of physiological concentrations of insulin to the isolated plasma membranes. This effect suggests that direct regulation of calcium homeostasis may represent an important event in the mechanism of action of insulin.

The high affinity Ca^{2+}-ATPase of rat adipocyte plasma membranes had an apparent half saturation constant ($K_{0.5}$) of 0.14 ± 0.04 μM (mean ± s.e.m. of eight experiments as in Fig. 1) for ionised calcium. A Hill plot of the data in Fig. 1 yielded a straight line with a Hill number of 1.5 (Fig. 1 inset). The maximal activity of the high affinity Ca^{2+}-ATPase was 196 ± 41 nmol $^{32}P\,mg^{-1}\,min^{-1}$ (mean ± s.e.m., five experiments) in membranes stored for less than two days. Activity decreased markedly after longer storage. Another saturable component appeared at higher calcium concentrations ($K_{0.5} \simeq 74$ μM), indicating the presence of a low affinity site similar to that previously reported for this tissue[10]. The high affinity enzyme yielded a biphasic response to varying ATP concentrations, also representing the sum of two saturable components, one with $K_{0.5} \simeq 0.8$ μM, the other with $K_{0.5} \simeq 27$ μM (data not shown). The presence of 20 mM sodium, 20 mM potassium or 0.5 mM ouabain did not affect the Ca^{2+}-ATPase, but activity was completely inhibited by 0.2 mM lanthanum. The enzyme had an absolute requirement for the endogeneous magnesium that was present in the plasma membrane preparation. Chelation of magnesium by *trans*-cyclohexane-1,2-diamine-*N*, *N*, *N'*, *N'*-tetraacetic acid

0028-0836/79/410495—03$01.00

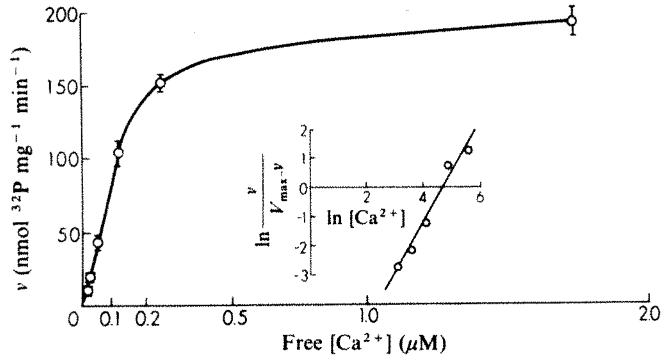

Fig. 1 Calcium dependence of the high affinity Ca^{2+}-ATPase in adipocyte plasma membranes. Isolated adipocytes were prepared from the epididymal fat pads of 120 g Sprague–Dawley rats[35] and the plasma membrane fraction obtained by a modification of the method of McKeel and Jarett[11] in which EDTA was omitted from the fractionation and homogenisation media[36]. The membrane fraction used in these studies has been previously characterised and has been shown to be highly enriched in plasma membranes by the use of the specific marker enzymes adenylate cyclase and 5′-nucleotidase[37]. The distribution of the high affinity Ca^{2+}-ATPase was shown to parallel the distribution of 5′-nucleotidase among the subcellular fractions (unpublished observations). These plasma membranes, which specifically bind ^{125}I-insulin[38], were either used immediately or within two days after storage at −70 °C. Ca^{2+}-ATPase activity was quantitated by monitoring ^{32}P released from γ ^{32}P-ATP and is expressed as nmol ^{32}P per mg protein per min[39]. Protein values were obtained by a previously described method[40]. The assay medium contained 20 μg protein ml^{-1} with 200 μM EGTA, 100–200 μM $CaCl_2$ (equivalent to 0.02–1.80 μM free Ca^{2+}), 1 mM Na_2ATP, 20 mM Na azide and 12.5 mM Tris-PIPES, *p*H 7.5 at 37 °C. Endogenous calcium in the assay medium was determined to be 4.5–5.0 μM by analysing the stock reagent solutions used by atomic absorption spectroscopy[41]. The total calcium concentrations used to calculate the ionised component take into account the endogeneous calcium present in the reagents. Ca^{2+}-ATPase activity was determined by subtracting values obtained with EGTA alone from those obtained with calcium plus EGTA. Each point represents the mean ±s.e.m. of quadruplicate determinations. Inset: Hill plot of the data. Free [Ca^{2+}] was calculated using a Ca-EGTA apparent association constant of $10^{7.832}$ M^{-1} whch was determined for *p*H 7.5 as described by Portzehl *et al.*[3]. The concentration for ionised calcium was corrected for any effect of ATP using the equations described by Portzehl *et al.*[3] and Schatzmann[42] and a Ca-ATP apparent association constant of $10^{3.930}$ M^{-1}, calculated at *p*H 7.5. All cation–ligand association constants were obtained from Sillén and Martell[43].

(CDTA), which has a high affinity for magnesium, totally abolished Ca^{2+}-ATPase activity. Activity could be fully restored by the addition of micromolar concentrations of free magnesium.

The high affinity Ca^{2+}-ATPase was located predominantly in the plasma membranes. This was determined by assessing its relative distribution among subcellular membrane fractions. The specific Ca^{2+}-ATPase activities in mitochondrial and microsomal (enriched in endoplasmic reticulum) fractions were 10 and 32%, respectively, of that of the plasma membrane fraction and could be accounted for by plasma membrane contamination[11,12].

Direct addition of insulin to the plasma membranes resulted in a highly significant decrease in Ca^{2+}-ATPase activity at various calcium concentrations in the region of the $K_{0.5}$ for calcium (Table 1). The per cent inhibition by insulin was greatest at the lowest calcium concentration and became less at higher concentrations, suggesting that insulin interaction with the plasma membranes may result primarily in a decreased affinity of the enzyme for calcium. The specificity of the insulin effect was shown in two ways. First, the inhibitory effect was concentration dependent over the physiological range for insulin (Fig. 2), increasing sharply between 0 and 50 μU insulin ml^{-1} and plateauing between 50 and 100 μU ml^{-1}. This concentration dependence is similar to other physiological responses to insulin such as glucose transport and oxidation[13]. Second, direct addition of equimolar concentrations of either desoctapeptide insulin, an analogue which has ~1% of the biological activity of insulin, or insulin which had been inactivated by boiling for 15 min did not inhibit the Ca^{2+}-ATPase. A similar inhibition was observed in plasma membranes prepared from cells which were pretreated with 100 μU insulin ml^{-1} at 37 °C for 15 min compared to plasma membranes simultaneously prepared from control cells[14] (data not shown). As the same effect is also seen in the intact cell, this similarity suggests that inhibition of the Ca^{2+}-ATPase by the direct addition of insulin to the plasma membranes is not an artefact.

The characteristics of the high affinity Ca^{2+}-ATPase in adipocyte plasma membranes strongly suggest that it may provide the enzymatic basis for a pump which extrudes calcium from the cell analogous to the well-characterised calcium transport enzyme in red cell plasma membranes[5]. Both enzymes are similar in that they: (1) require magnesium, (2) possess a $K_{0.5}$ for calcium close to the concentration of ionised calcium in the cytoplasm, (3) have similar low and high affinities for ATP, (4) are relatively independent of sodium or potassium ions, (5) are insensitive to ouabain, (6) are completely inhibited by lanthanum, and (7) possess a Hill number greater than one and less than two[5,15,16]. It is not surprising that such a calcium extrusion pump may exist in adipocytes as its presence has previously been suggested from calcium flux studies using intact cells[17].

An insulin-induced inhibition of calcium extrusion via inhibition of a high affinity pump enzyme could be a critical event in the mechanism of insulin action. Several observations may be related to this proposal. First, pretreatment of cells with insulin results in an increase in calcium bound to subsequently isolated adipocyte plasma membranes[18] and skeletal muscle sarcolemma[19]. Increased cytoplasmic calcium resulting from the inhibition of a calcium pump may regulate the availability of calcium for binding to specific sites on the plasma membrane. This increase in bound calcium could be responsible for the known effect of insulin to hyperpolarise muscle[20] and fat cells[21], as calcium has been shown to influence membrane permeability[22,23] and the membrane potential[24-26] of other electrically inexcitable cells. Second, the observations reported here could

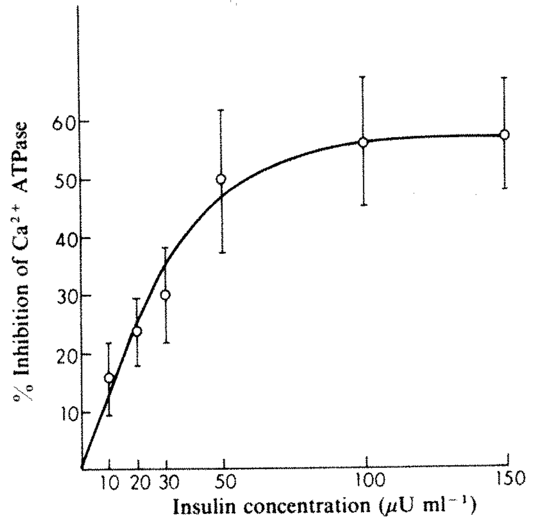

Fig. 2 Concentration-dependent inhibition of the high affinity Ca^{2+}-ATPase by insulin. Assay conditions were identical to those described in Fig. 1 and Table 1. Each point represents the mean ± s.e.m. of results obtained from four different membrane preparations. Free [Ca^{2+}] is 3.5×10^{-8} M.

also relate to insulin's regulation of glucose transport and membrane phosphorylation. Both membrane-bound calcium[27] and membrane phosphorylation[28] have been implicated in the regulation of glucose transport, and ATP has been reported to have a permissive effect on insulin-stimulated glucose transport[28]. Also, direct addition of insulin to these adipocyte plasma membranes has recently been shown to specifically inhibit the phosphorylation of two protein bands[29]. One is a 120,000 molecular weight (MW) plasma membrane protein; the other a 42,000-MW protein which originates from the small amount of mitochondria present in the preparation and has been identified as the α subunit of pyruvate dehydrogenase, an insulin-sensitive enzyme[29]. The unidentified insulin-sensitive 120,000 MW plasma membrane protein could represent the high affinity Ca^{2+}-ATPase as the analogous red cell Ca^{2+}-ATPase phosphoprotein has a similar molecular weight[30].

Table 1 Inhibitory effect of insulin on Ca^{2+}-ATPase activity at different free calcium concentrations*

	Ca^{2+}-ATPase activity ($nmol\ ^{32}P\ mg^{-1}\ min^{-1}$)			
Free $[Ca^{2+}]$	Control	+Insulin	% Inhibition	Significance
4.2×10^{-8} M	28.7 ± 6.7	16.9 ± 4.4	43.1 ± 7.7	$P<0.01$ ($n=9$)
7.1×10^{-8} M	49.6 ± 8.0	38.4 ± 7.3	25.1 ± 9.8	$P<0.02$ ($n=8$)
1.6×10^{-7} M	104.1 ± 19.1	92.4 ± 17.5	13.3 ± 3.1	$P<0.01$ ($n=7$)

* Assay conditions were identical to those in Fig. 1. Insulin was added to a final concentration of 100 μU ml^{-1} from a stock solution containing 0.1% bovine serum albumin (BSA). The final BSA concentration in each assay was 0.00125%. Controls contained an identical concentration of BSA. Results are expressed as the mean ± s.e.m. of *n* different membrane preparations. Significance was determined using the two-tailed paired *T*-test.

Increased cytoplasmic calcium resulting from inhibition of a calcium extrusion pump could directly regulate a variety of insulin-sensitive calcium-dependent enzymes including glycogen synthetase[31], hormone-sensitive lipase[32] and pyruvate dehydrogenase[33]. Alternatively, this increased calcium could mediate a variety of intracellular processes via binding to a calcium-dependent regulatory protein, which has recently been identified in the cytoplasm of adipocytes[34].

Thus these data demonstrate a direct effect of insulin on a high affinity Ca^{2+}-ATPase in the plasma membrane. Although further work is necessary to elucidate its role in insulin action and the mechanism whereby insulin inhibits this enzyme, our observations imply an important and fundamental role of calcium in the mechanism of insulin action.

Evidence for a charge-shift electrochromic mechanism in a probe of membrane potential

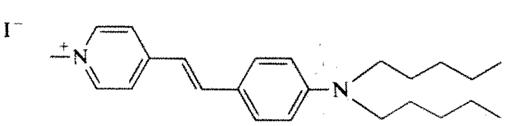
Extrinsic optical probes have become important tools for monitoring membrane potential, with probes now available for many tissue or cell suspension systems[1]. In each case that has been studied in detail[2–4], it seems that the mechanism involves a shift in the equilibrium population of the probe from one chemical environment to another in response to the transmembrane potential; the environments perturb the probe's spectrum differently. As this indirect mechanism involves a redistribution of dye between chemical environments that are likely to vary if a given probe is transferred from one membrane to another, a potential probe that is effective and calibrated for all membrane systems has not been realised. We present here evidence for a direct response of a probe chromophore to the electric field across membrane systems. The results suggest it might be possible to develop a universal set of membrane probes.

The probe used is the first to emerge[5] from a recently developed theoretical methodology[6]. According to this theory, the probe, 4-[*p*-(dipentylamino)styryl]-1-methyl-pyridinium iodide (di-5-ASP), has a ground state charge distribution which



favours orientation of the pyridinium ring near the aqueous interface, with the probe long axis orientated perpendicular to the membrane surface. The theory also predicts that, upon photoexcitation, the centre of positive charge will undergo a shift from the pyridinium end to the aminophenyl end of the chromophore. A transmembrane electric field should therefore induce a direct electrochromic shift[7,8] of the absorption spectrum of di-5-ASP[6].

The spectral responses of di-5-ASP bound to a hemispherical bilayer membrane of oxidised cholesterol[9] were used to provide experimental evidence for this predicted mechanism. The apparatus for determination of potential dependent fluorescence changes is shown in Fig. 1. Absorbance changes were determined with an apparatus essentially identical to that previously described for experiments with a planar bilayer[3].

An important criterion for electrochromism is that the first derivative of the absorption (or excitation) spectrum closely matches the response spectrum[10]. Application of this criterion to di-5-ASP is illustrated in Fig. 2; there is a small deviation,

0028–0836/79/410497—03$01.00

probably because the most responsive probe molecules are those orientated perpendicular to the membrane and these, in turn, have shorter wavelength absorption[11]. Figure 2 also illustrates how the probe senses the reversed potential when it is applied to the inside of the membrane. Hyperpolarisation of the membrane causes a blueshift of the spectrum when probe is applied to the inside and a redshift for probe bound to the outer surface, consistent with the behaviour predicted for a charge shift electrochromic mechanism[6]. On the other hand, an 'on-off' mechanism[3] would predict the opposite behaviour, as membrane bound di-5-ASP is blueshifted with respect to aqueous di-5-ASP[11].

The orientation dependence alluded to above is demonstrated in Fig. 3. The probe has a strong tendency to align perpendicular to the membrane surface[11], a feature which was an important design consideration. Fig. 3 shows that the response to potential is even more sensitive to orientation, showing a dichroism of ~80:1 at 480 nm. This can be easily rationalised in terms of electrochromism, as the small population of probes capable of absorbing light polarised parallel to the membrane would also have a relatively lower interaction with the transmembrane electric field.

A true electrochromic response is instantaneous on the time scale of any event which requires movement of nuclei, such as the development of a membrane potential. We have determined that, within the admittedly slow time scale required for charging of the hemispherical bilayer (100 μs), this condition is met for the absorption response of di-5-ASP.

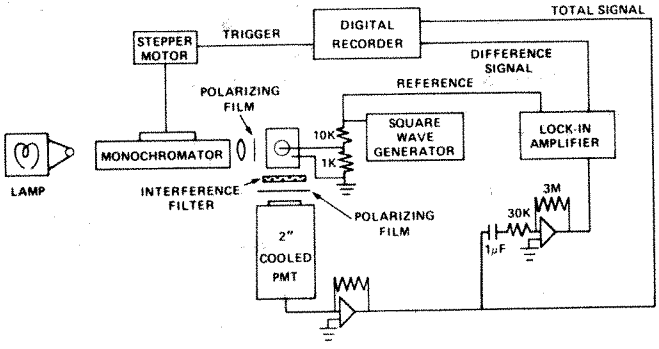


Fig. 1 System for the determination of corrected excitation and potential response spectra from probe-labelled hemispherical lipid bilayers. [System components are: Oriel 100-W quartz-halogen source, powered by Sorensen d.c. supply (DCR40-25B); Instruments SA model H20V monochromator with stepping motor and controller; 570 nm 2×2 inch interference filter (Ditric Optics); EMI-9558QA photomultiplier in Pacific Photometric Instruments model 3463 thermoelectrically cooled housing; Princeton Applied Research 5203 lockin amplifier-tuned amplifier; B&K Precision square wave generator; Bascom Turner 8110 recorder.] A decane solution of oxidised cholesterol[9] was used to prepare hemispherical bilayers. The solution was lightly brushed along the bottom of a 100 mM KCl solution contained in a 2 mm i.d. polyethylene tube which was attached to a micrometer syringe. The tube was immersed in 100 mM KCl contained in a cuvette, and a hemispherical bilayer was formed via gentle pressure from the syringe[9]. The square-wave potential pulses were applied through Ag-AgCl electrodes in the tube and the cuvette. The appropriate quantity of probe was added to the aqueous KCl as a 3 mM solution in ethanol; the total ethanol concentration was always below 0.3%. (Probe synthesis as in ref. 11). Since membrane-bound di-5-ASP fluoresces ~100 times more strongly than aqueous di-5-ASP, fluorescence detection is an effective way of isolating the membrane response; also, the emission interference filter rejects aqueous fluorescence ($\lambda_{max} = 620$ nm) but passes membrane fluorescence ($\lambda_{max} = 575$ nm). One of the key components of the system is the digital recorder which allows simultaneous acquisition of response spectra and excitation spectra. A rhodamine B quantum counter was used to generate a calibration curve, stored on the recorder's floppy disk, to correct the experimental spectra for the wavelength dependence of the exciting light intensity.

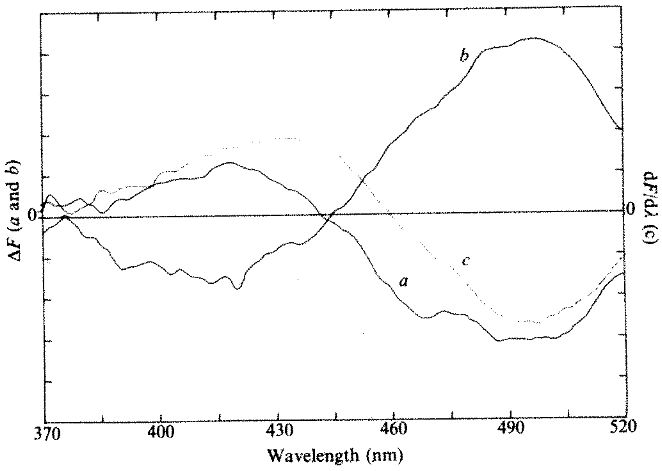

Fig. 2 Corrected response of the probe excitation spectrum to a 100 mV potential pulsed at 200 Hz. Apparatus described in Fig. 1. *a*, 3 μM probe applied outside the bubble; *b*, 3 μM probe inside; *c*, first derivative of the corrected excitation spectrum.

In addition to providing positive evidence for charge-shift electrochromism, the experimental results argue against the more common mechanisms[2-4] adopted by potential probes. At low lipid : probe ratios, aggregation of di-5-ASP can be observed in the membrane, detected by a blueshift in the absorbance and a quenching of fluorescence (L. M. L. and L. S., unpublished results); the similarity of the absorption response (Fig. 3) and the excitation response (Fig. 2) spectra, rule out the involvement of these non-fluorescing aggregates in the mechanism. A reorientation mechanism[12] is precluded by the results of Fig. 3; such a mechanism would require responses of opposite sign for the two polarisations. Another possible, and in this case unprecedented, process involves electrophoretic movement of the probe from one membrane site to another, with the two environments sufficiently different to induce a spectral shift. In some recent experiments[13] we have found essentially identical spectra with an electrically neutral analogue of di-5-ASP; this is strong evidence against the involvement of simple electrophoresis in the mechanism.

Electrochromism will assure a fast, well characterised and, perhaps, uniform response to membrane potential which may provide a special niche for di-5-ASP within the large repertoire of optical probes. Some of its other characteristics will be equally important in determining its usefulness, however. As $\Delta F/F$ is as

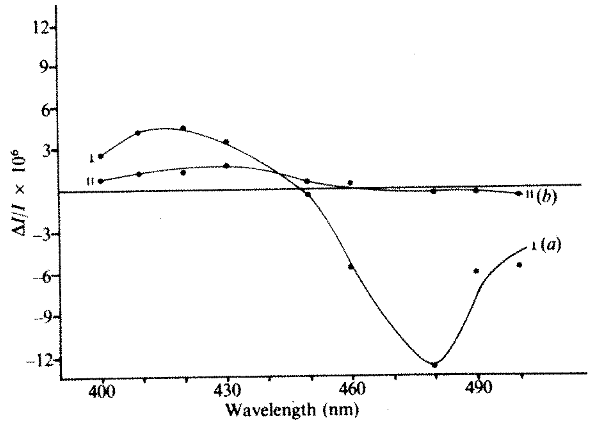

Fig. 3 Response of the absorption spectrum of 5 μM probe to 100 mV potential steps applied across the hemispherical membrane at 200 Hz. *a*, Incident light focused on the bottom $\frac{1}{8}$ of the bilayer and polarised perpendicular to this approximately planar area; *b*, polarisation parallel to the membrane. The apparatus has been previously described[3].

large as 5% for a 100 mV change in potential when exciting near the red wing of the absorption band, it is likely that monitoring fluorescence will provide the best signal. The probe binds strongly to membranes (in lipid vesicle experiments[11] we were unable to detect unbound probe even at a 1 : 1 lipid : probe ratio). The membrane-probe fluorescence is blueshifted by ~40 nm (to 575 nm) and is ~100 times more intense relative to aqueous probe; this provides obvious practical advantages in some applications, but would lower the relative change in fluorescence in an axon experiment, for example, as a result of high background fluorescence from the Schwann cells. The photostability of di-5-ASP appears good, a 3 mM ethanol solution having survived 2 years on an open shelf, so that high intensity excitation could be used to reduce shot noise; the question of photodynamic damage, however, is still open.

Di-5-ASP was the first 'charge-shift' probe to be examined, as much because of its simple preparation as its theoretical promise. The results presented here suggest that it will be worthwhile to develop new charge shift probes which may fit other spectral windows and be even more sensitive. The operation of these probes does not involve a delicate field-dependent balance between different chemical environments, so this approach may provide a universal set of spectroscopic potential probes.

The molecular structure of lecithin dihydrate

Robert H. Pearson

Medical Foundation of Buffalo and Electron Optics Laboratory, Biophysics Department, Roswell Park Memorial Institute, Buffalo, New York 14263

Irmin Pascher

Department of Structural Chemistry, Göteborg University, POB, S40033 Göteborg, Sweden

Lecithin is a major structural component of biological membranes[1,2]. Because of their amphipathic nature, lecithin and related phospholipids tend to aggregate as bilayer structures in which the hydrophilic head groups are orientated towards the surface and the hydrophobic hydrocarbon chains towards the interior. A detailed knowledge of the three-dimensional structure of lecithins will aid in the understanding of their role in membrane structure and function, but is still lacking. To this end we have now crystallised and solved the molecular structure of 1,2-dimyristoyl-*sn*-glycero-3-phosphorylcholine (DMPC), a lecithin species in the naturally occurring configuration. This compound crystallises from a water-containing solution, with two water molecules (5% w/w) of hydration.

The crystals were grown from commercially available material (Sigma, 98% pure) which had been further purified by recrystallisation from an ether/ethanol/water solution. In this solvent the nucleation of the crystals is accomplished by lowering the temperature of the solution to 14 °C, at which a flocculent precipitate appears. Once nucleated, growth can occur at any temperature between 0 °C and 22 °C, but above 22 °C the crystals redissolve. The crystals are monoclinic, space group $P2_1$, with two molecules in the asymmetric unit. Unit cell parameters are: $a = 8.72$, $b = 8.92$, $c = 55.4$ Å and $\beta = 97.40°$. Reflection data were collected by a peak measurement technique on a GE-XRD6 manual diffractometer. Of the 4,800 reflections thus collected, 1,931 were considered observable by the 2σ criterion. To maintain the crystals and improve high-angle data quality, the crystals were kept below 20 °C at all times and data were collected at 10–15 °C.

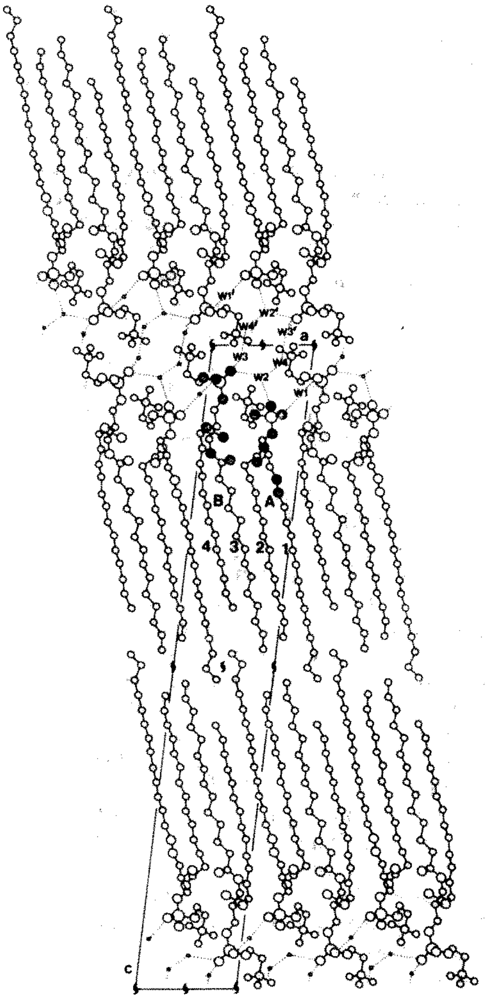

Fig. 1 Molecular arrangement of dimyristoyl lecithin dihydrate projected onto the *ac*-plane. The two molecules A and B of the asymmetric unit are shown with shaded oxygen atoms. The notation of the water molecules of hydration is given for a representative part of the hydrogen bond system (dotted lines) at the polar bilayer interface. The position of the remaining water molecules is indicated by small circles only. The break in the hydrogen bonds at W3' is intended to convey the helical nature of the water structure; connection of this bond leads to the phosphate oxygen of one unit below.

The structure was solved by Patterson and Fourier techniques. The positions of the two phosphorus atoms were found in the Harker sections of the Patterson map and difference Patterson map (where the contribution of the chain carbons had been removed). The remainder of the two molecules in the asymmetric unit was found in successive Fourier maps. Least-squares refinement with isotropic temperature factors (using the Nonius CAD-4 software system for the PDP-11 computer) has reduced the residual factor to 17.4%. The refinement procedure is being continued. An increase in the number of parameters by introducing anisotropic temperature factors is, however, not considered compatible with the number of observed reflections.

0028-0836/79/410499—03$01.00

The molecules are arranged in a bilayer structure with strong hydrogen bonding in the polar portions of the crystal (Fig. 1). The two molecules (A and B) in the asymmetric part of the unit cell are displaced from one another in the direction of the bilayer normal by 2.5 Å, or one whole zigzag unit of a hydrocarbon chain. Due to this displacement the bulky phosphorylcholine groups require a rather small area (38.9 Å^2 per molecule) of the layer surface which allows the two hydrocarbon chains to be almost perpendicular (78°) to the bilayer boundary. This type of offset may be related to the displacement of molecules observed in the rippled $P\beta'$ structure of lecithin bilayers in more fully hydrated conditions[3,4]. Phosphatidylethanolamine (PE), which has a smaller polar group, does not form such rippled bilayers. In the crystal structure of 1,2-dilauroyl-DL-phosphatidylethanolamine (DLPE)[5,6] the molecules occupy practically the same area of 38.6 Å^2 in the layer plane but align with their polar groups parallel to the bilayer surface, without a mutual displacement in direction of the bilayer normal. A corresponding arrangement of phosphorylcholine groups which is observed in the crystal structure of the lysolecithin analogue, 1-lauroyl-propandiol-3-phosphorylcholine monohydrate (LPPC)[7], requires an area per molecule of 52.1 Å^2. Although there are many common features in the conformation of the molecules in the crystal structure of DLPE and DMPC, a significant difference exists with respect to the interaction between the polar groups. In DLPE the $-NH_3^+$ group forms superimposed hydrogen bonds/salt bridges 2.8 Å long with unesterified phosphate oxygens of adjacent molecules. In DMPC (and LPPC) the nitrogen atom of the bulky $-N(CH_3)_3^+$ group comes no closer to the phosphate oxygens than 4.5 (3.7) Å. Instead, the non-ester oxygens which share the negative charge are separated and shielded by water molecules of hydration. Two water molecules (W1 and W2) are located between the phosphate oxygens of molecules A and B and thus form an infinite hydrogen-bonded phosphate (A)–water–phosphate (B)–water ribbon (Fig. 1) which provides stability in the *a*-axis direction of the bilayer plane. A similar phosphate–water ribbon is observed in the crystal structure of LPPC. The two other water molecules (W3 and W4) are hydrogen bonded to one phosphate oxygen of molecule B and to water molecule W2, respectively, and establish a linkage across the bilayer interface with the corresponding symmetry-related water molecules (W3′ and W4′) of the adjacent bilayer. Thus, a helical water structure about the two-fold screw axis is formed (see Fig. 1) which provides structural stability between the bilayers and in the *b*-axis direction of the bilayer plane.

The lateral arrangement of the hydrocarbon matrix is not consistent with earlier known simple chain packing modes. The orientation of the chain planes is alternately parallel and perpendicular to each other and resembles to some extent the hybrid chain packing modes[8] observed for other double chain lipids. The cross-section of 19.0 Å^2 per chain also corresponds to that of cerebroside[9] (19.1 Å^2), whereas DLPE is slightly larger (19.3 Å) due to its shorter chains. Note, however, that the hybrid packing in DMPC is well defined near the carboxyl end only. Towards the methyl end the chain planes are twisted to a mutually parallel orientation resembling a triclinic parallel (T∥) chain packing mode. This successive change in chain orientation indicates the close relationship between this hybrid subcell and the hexagonal chain arrangement with increased rotational disorder, as has been reported for the gel state of fully hydrated bilayers[3,4]. The small chain tilt of 12° which is observed for DMPC, but not for DLPE (0°), is due to the minute differences in molecular area (+0.3 Å^2) and chain packing density (−0.3 Å^2, see above).

Figure 2 is a detailed picture of the molecular conformation of the two DMPC molecules. The main difference between the two molecules concerns the conformation and orientation of their polar groups. The phosphorylcholine chains are almost mirror images of one another as shown by the torsion angles listed in Table 1. These angles are very similar to those observed in the crystal structures of other phospholipids and phospholipid constituents, which are included in Table 1 for comparison. This preferred conformation common to all phosphorylcholine and ethanolamine compounds reflects the tendency of the ammonium nitrogen to fold back towards the phosphate group so as to minimise the distance between the groups of opposite charge.

The phosphorylcholine groups of the two DMPC molecules make small angles with the bilayer surface. The **P–N** vectors are 4.3 and 4.5 Å long and inclined to the plane of the bilayer by 17° and 27° for molecules A and B, respectively. The somewhat more extended conformation of the molecule B polar group apparently arises from its more intimate participation in the water structure and its interaction with charged groups of the adjacent bilayer. This stretching and increased inclination of the polar group (which mainly affects torsion angle α_4 (see Fig. 2 and Table 1)) might also be expected in natural membranes when they become associated with ions. The cadmium chloride complex of GPC[10] listed in Table 1 reflects the response of the polar group conformation to the proximity of metal ions, and NMR studies on lecithin in the presence of polyvalent cations[11] confirm this.

The most obvious conformational difference between the two DMPC molecules, however, is in the orientation of the polar groups with respect to the hydrophobic parts. In molecule A the phosphorylcholine group points away from its own diglyceride part, but is close to it in molecule B. These two orientations are due to different conformations about the $C_{(3)}$–$C_{(2)}$ bond of the glycerol moiety (see Fig. 2 and Table 1). The torsion angle, θ_1, about this bond is +58° (+*gauche*) and +169° (*antiplanar*) in molecules A and B, respectively. In DLPE another staggered conformation ($\theta_1 = -52°$; −*gauche*) is adopted whereas in LPPC an eclipsed *synplanar* conformation ($\theta_1 = 28°$) is approached. This shows that there are no preferred conformations about the $C_{(2)}$–$C_{(3)}$ bond. This bond apparently allows rotational independence between the asymmetric (1,2-*sn*-configuration) and conformationally similar diglyceride moiety (see below) and the polar group which exists as mirror image conformers. Results from deuterium NMR studies[12] indicate that in both the gel and liquid-crystalline states of lecithin, such a rotation of the polar group takes place, and seems to be accompanied by a rapid

Table 1 Torsion angles of crystallographically determined phospholipid constituents*

		α_1	α_2	α_3	α_4	α_5	θ_1	θ_3	β_1	β_2	β_3	β_4	γ_1

Remaining β and γ torsion angles are approximately *antiplanar* (180°).

* For notation of torsion angles see Fig. 2 legend.

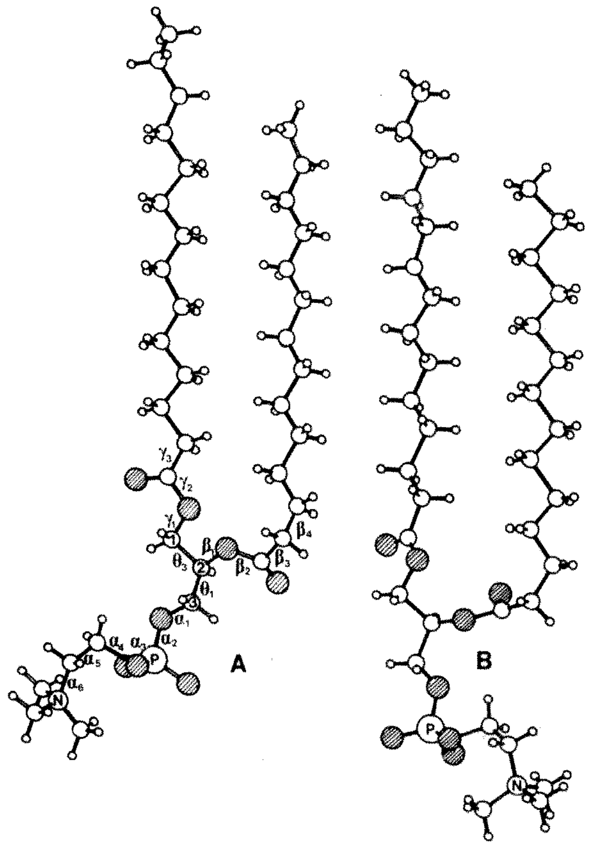

Fig. 2 Molecules A and B of dimyristoyl lecithin in a view along the unit cell *a*-axis. Hydrogen atoms are added at theoretically calculated positions to improve the perspicuity. The notation of torsion angles according to Sundaralingam[17] is indicated for molecule A. The figure illustrates the mutual 2.5-Å displacement of the two molecules in the direction of the hydrocarbon chains and the 3.7-Å offset between the two hydrocarbon chains within each molecule caused by the characteristic chain stacking.

inversion between enantiomeric conformations. The DMPC molecules A and B and also DLPE and LPPC obviously represent different energetically equally favoured stages of the freely rotating polar group.

In spite of the different orientations and mirror image conformations of the polar group, the diglyceride part is very similar in both DMPC molecules (Fig. 2). The three glycerol carbon atoms and the *sn*-1-fatty acid together form an *antiplanar* zigzag chain which is only slightly inclined (12°) from the layer normal. The initial part of *sn*-2-fatty acid extends perpendicularly (layer parallel) from this straight backbone but bends off at the second carbon atom to become parallel to the *sn*-1-chain. The same type of chain stacking is found in the DLPE crystal and, according to recent NMR studies[13], is also adopted by lecithin and phosphatidylethanolamine in hydrated bilayers and *Acholeplasma laidlawii* membranes. This diglyceride conformation must therefore be considered as a general, preferred feature in membrane phospholipid arrangements. The axial displacement of the two fatty acid chains of 3.7 Å by three methylene groups, which is caused by this chain stacking, is to some extent compensated in natural phospholipids by different chain lengths of the two fatty acids. In egg lecithin[14], for example, the predominant chain lengths in the *sn*-1 and *sn*-2 positions are 16 and 18 carbon atoms, respectively. This will reduce the interdigitation of the hydrocarbon chain ends at the bilayer centre.

In the DMPL structure the carbonyl oxygens of the fatty acid chains do not seem to take part in polar interactions, although the oxygens of the *sn*-2 chains (2 and 4 in Fig. 1) are exposed to the polar group region. These oxygens should become more easily available for interaction if the cross-section of the molecule is increased, due to either increased hydration of the polar groups and/or expansion of the chain matrix on transition to the liquid-crystalline state, which is the usual condition in natural bilayers. This accessibility of the carboxyl group of the *sn*-2-chain at the hydrophobic/hydrophilic interface of the lipid bilayer may also explain why enzymes which split fatty acids from phospholipids, such as lecithin cholesteryl acyl transferase and phospholipases of type A, have mostly evolved a specificity for this *sn*-2-fatty acid.

From available data it is obvious that the characteristic conformational features exhibited by DMPC in the crystal structure are also maintained in less ordered lecithin structures in an aqueous environment. The detailed three-dimensional structure presented here provides the necessary basis for a more conclusive interpretation of biochemical phenomena and physicochemical data recorded on model systems and natural membranes.

We thank Professors S. Abrahamsson and A. Hybl, and Drs W. Duax and S. W. Hui for assistance. DMPC was obtained from Dr D. Dorset, and the diffractometer made available by Dr Parthasarathy. Funds for computer usage were in part made available through NIH grant GM-19684 to the Medical Foundation of Buffalo.

Heat-shock induced proteins present in the cell nucleus of *Chironomus tentans* salivary gland

M. Vincent & R. M. Tanguay

Génétique Humaine, Centre Hospitalier de l'Université Laval, Québec, Canada

The heat shock (HS) system has been largely studied in *Drosophila* but the molecular mechanisms responsible for the induction of the heat shock genes as well as the function(s) and the intracellular localisation of the induced proteins is still unknown. It has previously been shown that the HS puff induction is accompanied by a local increase of nuclear non-histone proteins (NHP) but the nature of most of the proteins accumulating is unknown[1]. We have investigated the effects of a heat shock on *Chironomus tentans* salivary glands, a system where it is possible to study constituents in various subcellular or intranuclear regions including individual puffs[2,3], by microdissection. We report here evidence that at least two of the polypeptides synthesised in response to the heat shock migrate to the nucleus. Furthermore, these two proteins appear to have a broad intranuclear distribution, as shown by their presence in the various microdissected nuclear fractions.

At the cytoplasmic level, the heat shock (39 °C) response of *Chironomus tentans* salivary glands is similar to that observed in *Drosophila* (Fig. 1*a*, *b*). Several new proteins appear (arrows,

0028–0836/79/410501—03$01.00

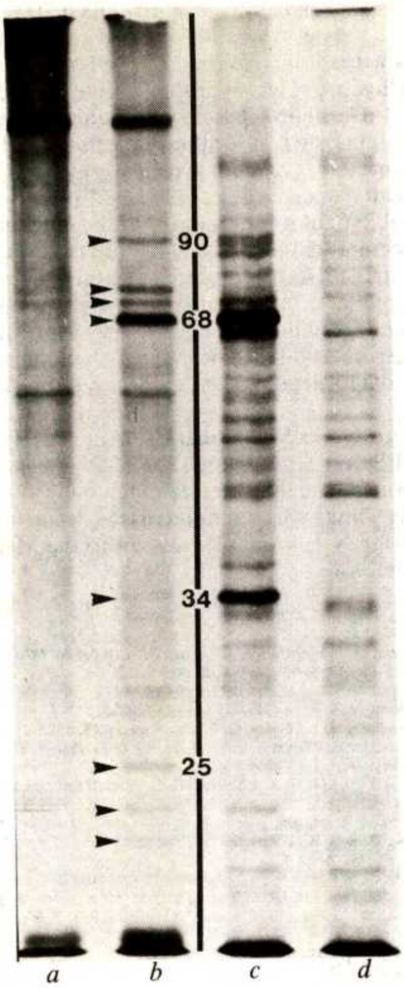

Fig. 1 Photograph of a fluorogram showing the labelled proteins from the cytoplasms of control *a* and heat-shocked larvae *b* and from the nuclei of heat-shocked *c* and control larvae *d*. Larvae were incubated at 39 °C for 10 min, and control larvae at the same developmental stage, were kept at room temperature. For both treatments, 10 salivary glands were excised and incubated for 90 min in 50 μl Cannon's modified medium (without leucine) supplemented with 100 μCi ^{3}H-leucine. After fixation of the glands in absolute ethanol:acetic acid (3:1), the glands were microdissected to obtain pure intracellular compartments. The proteins from the pooled components were extracted and analysed on a 8.75% acrylamide-SDS slab gel as described elsewhere[4,5]. The labelled polypeptide bands were revealed by fluorography[7]. In this experiment, 200,000 c.p.m. of each microdissected extract were put on the gel which had been exposed for 3 d. Arrows on *b* indicate cytoplasmic HS peptides. Approximate molecular weights, in kilodaltons are indicated in the middle of the photograph.

Fig. 1*b*) with a major one of molecular weight (MW) about 68,000. (R.M.T. and M.V., in preparation.) This protein apparently has the same MW as the major heat-shock induced peptide in *Drosophila* cell cultures and salivary gland cells. Also, normal protein synthesis is repressed in response to a 39 °C heat shock (by ~50%), as in *Drosophila*. Thus, even though the sites and numbers of heat-shock induced puffs have not been studied in *Chironomus*, it seems that its response at the protein synthesis level is quite similar to that of *Drosophila*. *In vivo* treatments (5–20 min at 39 °C) gave similar results with the exception of a gradual decline in total protein synthesis. More drastic treatments, such as a 40-min shock at 39 °C or a 10-min shock at 41 °C, resulted in an almost complete shutdown of protein synthesis (data not shown).

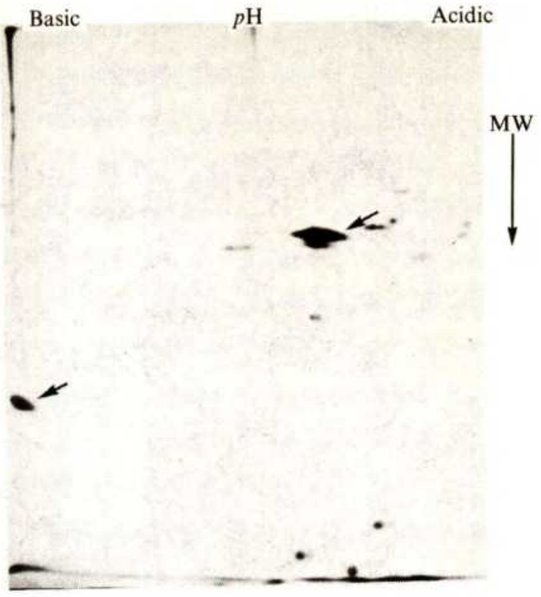

Fig. 2 Photograph of a two-dimensional fluorogram showing the labelled proteins from the nuclei of heat-shocked larvae. Isoelectric focusing in the first dimension was carried out in 9.5 M urea and SDS-electrophoresis in the second dimension was on a 8.75% acrylamide gel as described by O'Farrell[8].

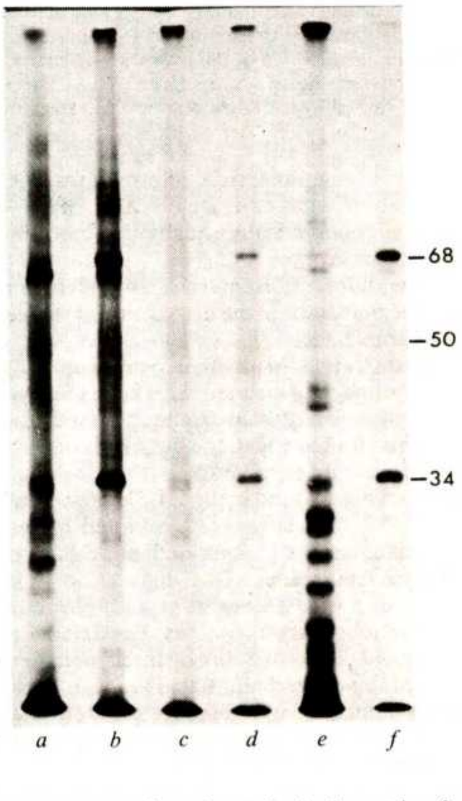

Fig. 3 Fluorogram of newly-synthesised proteins from subnuclear microdissected compartments. *a* Chromosomes from control glands; *b* chromosomes from heat shocked glands; *c* nuclear sap, control; *d* nuclear sap, heat shock; *e* nucleoli, control; *f* nucleoli, heat shock. Molecular weight markers were bovine serum albumin (68,000), γ-globulin heavy chain (50,000) and tropomyosin (34,000). Experimental procedure as described in Fig. 1 legend.

In a search for possible nuclear modifications accompanying the heat treatment, we analysed newly synthesised proteins from microdissected nuclei (Fig. 1*c*, *d*). The nuclear protein pattern from treated cells shows two major peaks, at MW 34,000 and 68,000 (Fig. 1*c*), not found in the control nuclei, the latter migrating similarly to the major cytoplasmic protein. However, the 34,000-MW protein, while being a major component of the HS nucleus, is barely visible on the HS cytoplasmic profile (Fig. 1*b*), suggesting a rapid migration of the polypeptide to the nucleus.

On the other hand, the two-dimensional pattern of the heat-induced nuclear proteins (Fig. 2) clearly established that these two peptides have distinct isoelectric points, arguing against a precursor–product relationship between them. These results provide the first indication for a nuclear role of some of the HS induced proteins.

Several minor bands on the HS cytoplasmic and nuclear profiles (Fig. 1*b*, *c*) are common to both of them. These could represent additional HS proteins which are also transferred to the nucleus. However, they could also result from minor contamination of the dissected nuclei with cytoplasmic material.

We examined the intranuclear localisation of these two proteins using microdissection techniques. The nuclei were dissected into three fractions—chromosomes, nucleoli and nuclear sap—and the proteins from each compartment were extracted and analysed by SDS-polyacrylamide gel electrophoresis as previously described[4,5]. In addition to containing the chromosomal proteins present in the control (Fig. 3*a*), the chromosome fraction from heat-shocked cells (Fig. 3*b*) shows two extra proteins with MWs of 68,000 and 34,000. These two proteins may be present in the HS-treated nuclear sap (Fig. 3*d*) simply because they are passing through it, but the possibility that they have some function there cannot be excluded. Finally, the nucleolar pattern shows some interesting features: the low molecular weight proteins characteristic of control nucleoli (Fig. 3*e*) are absent in the treated gland nucleoli, while the two HS-induced polypeptides are heavily represented in this fraction (Fig. 3*f*). In summary, these results show the migration to the nucleus of at least two newly synthesised HS-induced proteins which appear to have a general intranuclear distribution.

This provides new information about these proteins and suggests a nuclear role for some of them. There has also been an indication that HS proteins are present in *D. melanogaster* nuclei[6]. These proteins may be involved in a general mechanism responsible for the functional or morphological maintenance of the HS nucleus or in various processes such as the silencing of preexisting puffs and the transport or processing of the induced mRNAs.

We thank Mrs F. Biron for technical help and the MRC of Canada, grant MA-5278 to R.T. and a studentship to M.V.

Quaternary structure-induced photoreduction of haem of haemoglobin

Teizo Kitagawa

Institute for Protein Research, Osaka University, Suita,
Osaka 565

Kiyoshi Nagai

The Second Department of Physiology, Nara Medical College,
Kashihara, Nara 634, Japan

Spectroscopic studies have provided extensive information on the primary process of visual pigments and photoexcitation of chlorophyll as well as their effects on the surrounding polypeptide chain, but a dependence of photoreactivity on the higher-order structures of protein has been observed only rarely. Resonance Raman spectroscopy can reveal the vibrational frequencies of the chromophore in a molecule provided the excitation wavelength is in the absorption band of that molecule. As the visible absorption bands of haemproteins are due to $\pi\pi^*$ transitions of the porphyrin ring, we can selectively observe the vibrational frequencies of iron porphyrin during *in situ* interactions with immediate amino acid residues of protein when the wavelength of excitation light is close to the Soret or Q band. Correlation of some vibrational frequencies of haem with the oxidation and spin states of the haem iron has been studied in detail and an empirical rule has been established[1,2]. This method is therefore especially suitable for the study of an effect of higher-order structures of protein on the chromophore. We report here a photoreaction facilitated by a particular quaternary structure of protein—in various haemoglobins resonance Raman spectroscopy showed that reversible photoreduction of haem took place in the T state but not the R state.

Haemproteins containing iron porphyrin as a prosthetic group function as oxidases, oxygenases, carriers and reservoirs of oxygen, or electron carriers in a respiratory chain in most organisms. Haemproteins do not normally serve as photoreceptors—photodissociation of axial ligands such as O_2, CO and NO bound to the Fe^{2+} ion was previously the only known photoreaction of haemproteins[3]. Methaemoglobin has been thought to be photostable, but during resonance Raman studies of the quaternary structures of haemoglobin (Hb), we found that a haem of some met-Hb in the T quaternary structure (low affinity for oxygen), but not in the R quaternary structure (high affinity for oxygen)[4], was extensively photoreduced on irradiation by laser light at 441.6 nm. The apparent photoreduction of haem was reversible and dependent on the wavelength of the irradiated light.

Figure 1 shows the resonance Raman spectra of various Hb molecules in the frequency region 1,200–1,700 cm^{-1}. It is well established that in this frequency region the resonance Raman spectra of the two oxidation states are distinctly different[1,2]. Deoxy-Hb (Fig. 1*a*) and aquomet-Hb (Fig. 1*c*) exhibited the characteristic Raman lines of their oxidation states at 1,355 and 1,371 cm^{-1}, respectively. When inositol hexaphosphate (IHP), an effector stabilising the T structure, was added to aquomet-Hb, prominent Raman lines appeared at 1,371 and 1,355 cm^{-1} (Fig. 1*b*). Furthermore, extra Raman lines were also observed in a lower frequency region (not shown) and their frequencies (366, 341, 302 and 216 cm^{-1}) coincided with those of deoxy-Hb[5]. In the frequency region above 1,500 cm^{-1}, relative intensities of Raman lines were altered by laser irradiation and the intensified Raman lines reasonably corresponded to the Raman lines of deoxy-Hb. These facts suggested that the haem of aquomet-Hb in the T structure was partially photoreduced by laser irradiation.

Carp aquomet-Hb in the presence of 2 mM IHP is known to adopt the T structure[6]: in a stationary cell this gives the spectrum shown in Fig. 2*d*. There were Raman lines at 1,355 and 1,371 cm^{-1}, as for human aquomet-Hb, implying that carp aquomet-Hb in the T structure was also partially photoreduced. When the same sample was measured in the spinning cell (1,800 r.p.m.), the spectrum (Fig. 1*e*) was indistinguishable from that observed in the absence of IHP. It was previously noted that photodissociable haemproteins were apparently protected from photodissociation in the spinning cell[7]. The actual mechanism involves recombination of the ligand during passage of the

0028-0836/79/410505—02$01.00

molecules through the dark. Thus it is probable that in the spinning cell the photoreduced Hb re-oxidised while it passed through the dark. As in the spinning condition a Hb molecule was irradiated by laser light for 0.3 ms every 30 ms, the time required for re-oxidation must be less than 30 ms. The alternative would be that the photoreduction did not take place within 0.3 ms.

Figure 2 shows the Raman spectrum of carp aquomet-Hb in the presence of IHP measured at three different power levels of laser light. The Raman line of the photoreduced species at 1,355 cm^{-1} became relatively more intense when the power level was increased. A similar phenomenon was observed by Cheung *et al.*[8] for etioporphyrinato-Ni(II) excited at 404.6 nm. They reported that tight focusing of the incident laser light at the sample point resulted in a frequency shift of a Raman line from 1,384 to 1,375 cm^{-1} and weakening of other Raman lines. The present observation differs in that two Raman lines were observed simultaneously—one at 1,371 and one at 1,355 cm^{-1}. The line at 1,371 cm did not completely disappear even in an anaerobic condition and the intensity ratio, 1,371/1,355 cm^{-1}, was unaltered by prolonged irradiation (up to 1 h). The photoreduced species was not recognised on irradiation of laser light at 488.0 and 514.5 nm. Other met-Hb derivatives including fluromet-Hb, azidomet-Hb and cyanomet-Hb were almost equally photoreduced when IHP was present at neutral *p*H. All these facts indicated that photoreduction of the haem of met-Hb apparently took place when met-Hbs were in the T quaternary form but not in the R form, and that the photoreduction was reversible. Furthermore, the lifetime of the photoreduced species was extremely short.

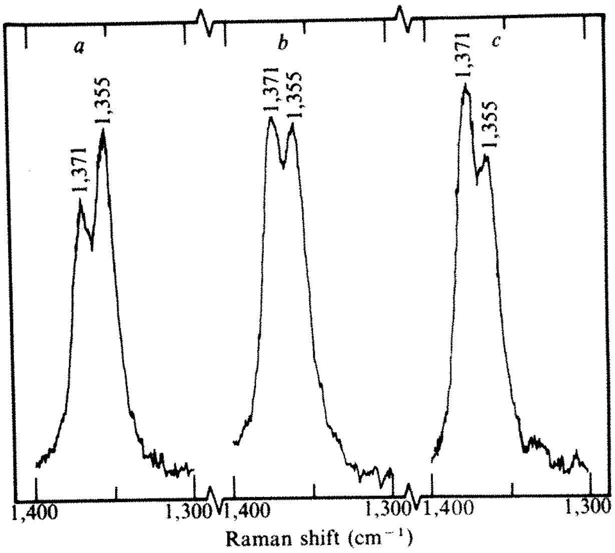

Fig. 2 Raman spectra of carp aquomet-Hb in the presence of 2 mM IHP in the frequency region 1,300–1,400 cm^{-1}. The Raman spectra were excited by the 441.6 nm line of He–Cd laser at the power level of *a*, 12 mW; *b*, 3 mW and *c*, 1.5 mW. Laser light was attenuated by the 1/4 and 1/8 ND-filters.

Photoreduction of haem, similar to that reported here, was recently observed for cytochrome oxidase on irradiation of laser light near the Soret band[9–11]; the electron donor was thought to be a flavin impurity. In the present case, however, the Hb solutions used for the T and R forms were identical except for the presence or absence of IHP. Therefore the electron donor for photoreduction is endogenous and may possibly be axial ligands of haem iron. Whatever the electron donor involved, this study suggested that an electron was reversibly transferred to haem from the donor only in the T structure while the oxidation state of the whole molecule remained unaltered, and that the rate of electron transfer depended on the wavelength of irradiated light, presumably as a result of the wavelength-dependent electronic excitation of the acceptor group.

We thank Kinmon Electric Co. for the use of a He-Cd laser, and Mr T. Ogawa for providing carp.

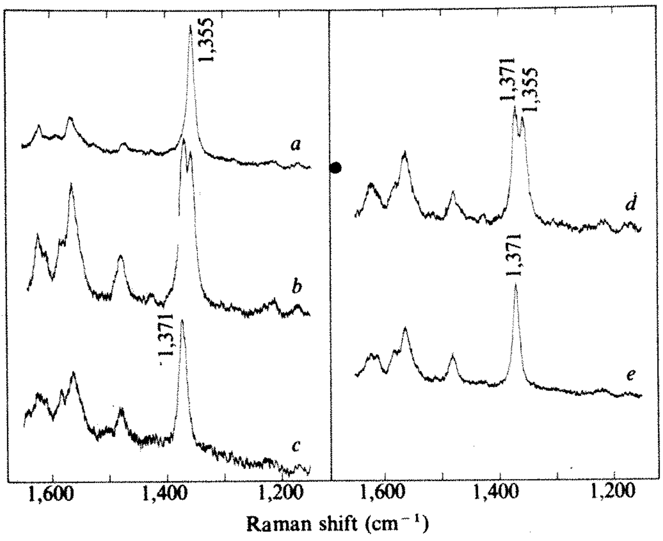

Fig. 1 Resonance Raman spectra of human and carp aquomet-Hbs in 0.05 M bis-Tris, 0.05 M Tris buffer *p*H 6.5 excited at 441.6 nm (He–Cd laser, Kinmon Electrics). *a*, Human deoxy-Hb A; *b*, human aquomet-Hb A in the presence of 2 mM IHP; *c*, human aquomet-Hb A in the absence of IHP; *d*, carp aquomet-Hb in the presence of 2 mM IHP measured in a stationary cell; *e*, the same sample as (*d*) but in a spinning cell (1,800 r.p.m.). Human and carp haemoglobin were prepared as described by Kilmartin and Rossi-Bernardi[12] and Tan *et al.*[13], respectively. Hb was oxidised at *p*H 6.9 by addition of 1.2 equivalence of $K_3Fe(CN)_6$ and then was stripped of phosphate by passage through a Dintzis column.

Using Iodine-125?

New Microvial*

- reduced exposure
- reduced contamination risk

Reduced exposure

The new packaging consists of 2 parts

- An outer plastic container incorporating a steel shield
- An inner plastic vial with a conical glass insert containing the iodide solution

Reduced contamination risk

The cap of the plastic outer container is keyed so that it can be used to unscrew the cap of the inner vial — no need to handle this vial from start to finish.

ICE AGES

M

: Solving the Mystery

Professor John Imbrie and
Katherine Palmer Imbrie

May 1979 £6.95 224pp 0 333 26767 2 illustrated

Knowledge that the world once endured an ice age has been widespread for more than a century. Indeed, the concept is now so familiar that nearly every winter storm prompts dramatic headlines: Is a new ice age upon us?

This book tackles that burning question and attempts to unfold, for the interested general reader and those with a more academic interest, the entire saga of the Ice Age 'mystery' – why ice ages occurred, what they were like, and when the next one is due.

It is written by one of the principal scientists on the multi-million dollar CLIMAP project which set out to study changes in the climate of the earth over the past 700,000 years. Out of the group's analytical work came an exciting by-product: confirmation of the correctness of one of the several theories of what causes ice ages to occur. The theory that was confirmed, and is now explained along with many others in ICE AGES, is the Milankovitch, or astronomical theory which sees periodical glaciation as the result of three regular movements the earth makes as it travels around the sun: changing ellipticity of the earth's orbit, "wobble" of the earth's axis, and the changing tilt of the earth's axis.

"ICE AGES is fascinating in its scientific interest and also as a detective story. I recommend it to all." Dr. William F. Libby, Nobel Laureate.

Oxford Books for Students

Physical Chemistry

P. W. Atkins

'It is a book of its time not only in content and outlook but in format and style too . . . . could well become a milestone in the development of text books of physical chemistry.' *Chemistry in Britain.* 'An important and original work.' *Education in Chemistry.* 'The author is to be congratulated on the production of such a good text and the publishers for its presentation at a price within the reach of students.' *British Book News.* £17.50 paper covers £7.95

Solutions Manual for Physical Chemistry

P. W. Atkins

This manual contains the author's detailed solutions of almost every one of the 1,060 problems contained in his textbook *Physical Chemistry.* It will be invaluable both to the instructors and lecturers who have adopted the parent text and to the students who use it themselves. Illustrated paper covers £4.50

Elementary Information Theory

D. S. Jones

Information theory is important to the designers of communication networks and electronic computers, and includes aspects of cryptography and linguistics. This book forms a one-term course for undergraduates in science and engineering. It begins with a short description of the relevant notions from probability theory. Then the quantity of information in a message is defined and its properties developed. The coding of messages is considered, followed by treatment of channel capacity, error-correcting codes, and continuous signals. £11 paper covers £4.95 *Oxford Applied Mathematics and Computing Science Series*

Biochemistry

Frank Bradley Armstrong and Thomas Peter Bennett

This book is an introductory text for first-year undergraduates studying biology, biochemistry, or chemistry at degree level. The topics treated include water as the solvent of life, cells as the biological units of molecular organization, proteins, carbohydrates, liquids and membranes, the basics of human nutrition, and hormones. £14

Thermodynamics and Statistical Mechanics

P. T. Landsberg

The basic ideas and mathematical formulations of thermodynamics are presented here in a concise and modern way. Topics covered include: negative temperatures; negative heat capacities; special and general relativistic effects; black hole thermodynamics; gravitational collapse; energy conversion problems; and efficiencies including simple heat pump theory. £8.50

The Solid State

An Introduction to the Physics of Crystals for Students of Physics, Materials Science, and Engineering

H. M. Rosenberg

The topics covered include basic crystal structure, diffraction of waves, dislocations, specific heat, phonons, thermal and electrical conductivity, the physics of p–n semiconductor junctions, and magnetic and dielectric properties. For the second edition a chapter on superconductivity has been added. £5.50 paper covers £2.95
Oxford Physics Series

Physical and Engineering Science for Technicians, Level I

R. J. Besanko and T. H. Jenkins

This new version of *General Engineering Science* is designed to cover the units in physical science and engineering science at Level 1 for students taking TEC Certificate and Diploma Programmes. Some additional material is included to satisfy college-devised units, and the book is also suitable for other courses at this level. Paper covers £2.95

Scientific Models and Man

The Herbert Spencer Lectures, 1976

Edited by Henry Harris

In these lectures a group of distinguished men from different disciplines describe how current work in their own subject is changing their view of the world. Scientific models have been enormously influential in transforming the way in which we look at ourselves and at the universe: this book gives some indication of the way the world is going to look tomorrow. £3.25

reviews

Members of the club

Thomas H. Jukes

The Eighth Day of Creation: The Makers of the Revolution in Biology. By H. F. Judson. Pp. 686. (Simon and Schuster: New York; Cape: London, UK, 1979.) $15.95; £7.95.

George Gamow, about 1954

THE book is in three sections. The first deals, in much detail, with events leading to the discovery of the structure of the DNA molecule. It is a comparatively straightforward topic. The third section is about the structure and function of protein molecules, and the procedures, especially crystallography, that were used in research with proteins. This subject, quite complex for the average reader, lends itself to logical treatment, and the author attacks it with obvious relish. He was helped by his friendly relationship with Max Perutz.

The intermediate section is about molecular biology from the time of the discovery of the DNA formula to the solution of the genetic code. This is a difficult amd controversial era for evaluation because of the involvement of many scientific groups, and this is therefore the most personalised and subjective part of the book.

The challenge to genetics and evolution, posed by Watson and Crick in 1953, was a biochemical one: to find out how information travelled from the gene to the phenotype. As described by Judson, enter George Gamow, an ebullient and articulate cosmologist. There followed a strange period in which the mysteries of molecular biology were planned to be solved by a special coterie called the "Tie Club", the membership of which was limited to 24, one for each nucleotide in DNA and each amino acid. Crick was the scoutmaster of the troop, and merit badges (ties and tie clasps) were awarded and issued by Gamow. Apparently, this cabal took itself seriously, and exchanged "Tie Club" letters, on scientific concepts and developments.

All who have followed molecular biology have impressions and memories of the years (1953–1965) between the announcement of the DNA helix and the completion of the genetic code. I suppose that leadership in science is based on a blend of performance and eloquence. Certainly the scientific stars who dominate Judson's narrative were great talkers, with dominant personalities. Francis Crick can hold a packed auditorium spell-bound by a loop of string and a description of supercoiling and writhing. No wonder Judson was swept away, and he tends to be reverent in the presence of the great. For example (page 92):

> "We now have standardized people with respect to their intake by giving them a standardized small-molecule diet" — he gestured towards the packet of Vivonex 100 — "which is immediately absorbed from the stomach into the blood stream, no digestion, the contents of the gut quickly disappear and the bacteria too. They are starved to death on this diet. Perfectly nutritious . . . ."

This prestidigitation by Pauling was swallowed by Judson, together with the Vivonex, and 2g of vitamin C. He says: "I'd been captured by that infectious grin and that unquenchable self-confidence . . . .". Self-confidence does not change the stomach wall, which, in the absorption of food, "behaves as if it were made of porcelain". If not, the liver would be promptly marinated by hydrochloric acid secreted in the gastric juice. Bacteria do *not* disappear from the gut when food is withheld.

A dinner at King's College (1971) inspires Judson to unctuous prose (p221):

> From my right, along the polished wood, there arrived a little trolley train on wheels, in the shape of a silver swan, with three parts joined by swivels, and each part bearing a decanter. A card said that the port was Taylor 1955, the white was Raventhaler Herberg Riesling Spatlese Cabinet 1959, and the red was Corton Les Maréchaudes 1962. Beyond Brenner sat a gray-haired woman, a computer mathematician from one of the women's colleges. Brenner leaned towards her. "There will be no difficulty in computers' being adapted to biology", he said, with clenched teeth. "There will be Luddites. But they will be buried".

Perhaps Sydney was getting a bit edgy about public objections to genetic manipulation.

Dounce's paper on coding (*Enzymologia,* **15**, 251; 1952) is given courteous but somewhat brief treatment on pages 247–248. His proposal was that groups of three consecutive bases in RNA each furnished the code for an amino acid; and Yčas (in *The Biological Code;* North-Holland: Amsterdam and London, 1969) states that Dounce " . . . . also suggested that the information in the RNA template may be stored in DNA. 'If . . . . genes are composed of deoxyribonucleic acid, then the deoxyribonucleic acid gene molecules would act as templates for ribonucleic acid synthesis, and . . . . the riboncucleic acid synthesized on the gene templates would then in turn become templates for protein synthesis in the nucleus or cytoplasm or both'. Dounce's proposal thus clearly stated what became known later as the 'sequence hypothesis', as well as the messsenger RNA concept.".

Even though Dounce's proposal preceded 1953, Judson devotes excessive space to free-swinging and palpably erroneous speculations on coding by Gamow. It must have been a blow that Nirenberg and Matthaei were not "members of the club" (p447), for according to Meselson, results by non-members were "unlikely to be correct" (p481). However, recovery from the shock was rapid.

Of course, it was the announcement by Nirenberg and Matthaei, and its consequences, that finally brought genetics within the grasp of biochemistry. Judson's criticisms (p487) that the experiments with random polynucleotides failed "to allow for synonyms" are not well taken. The degeneracy of the code was shown by the "shared doublets" and most of the coding assignments were correct; except that the sequence of bases in each triplet was not discernible until later. An epilogue soon followed, although Judson does not mention it: Fred Sanger got tired of waiting for his turn to use the amino acid analyser, so he decided to sequence nucleic acid molecules.. (He had previously shown everyone how to sequence proteins.) Place the amino acid sequence of a virus coat protein beside the sequence of the viral RNA molecule, and there you have the complete story — the direction of reading and all the codons. But, apparently, Fred spends too much time in the lab, and not enough in talking to historians.

Judson gives the genetic code the most perfunctory treatment of any major topic discussed, except for long summaries of early theoretical work that turned out to be in vain. The first preliminary indication of code composition was by Sueoka (1961) who showed that high A + T in DNA of bacteria was correlated with isoleucine, lysine, phenylalanine and tyrosine; high G + C with alanine, arginine and glycine in bacterial proteins.

Crick showed great insight in insisting that exactly 20 amino acids were used in protein synthesis (pp252-258). For years afterwards, biochemical authors still frequently talked of "about 20", or "about 22". Hydroxyproline in gelatin was particularly confusing. Asparagine and glutamine were often omitted although isotopic experiments had shown they were incorporated intact. Judson errs in stating that Gowland Hopkins, in 1901 "had been first, with tryptophan, to isolate an amino acid". Glycine was isolated from gelatin hydrolysate in 1820; tryptophan was seventeenth.

L to R: Jacob, Delbruck, Meselson, Rolfe, Stent and Brenner

Arthur Pardee, 1960

The story of the messenger concept is developed in detail. I well remember the excitement caused by the "DNA-like RNA" finding by Volkin and Astrachan in 1956. The statement that this work "could not quite be dismissed as the inconsequential and self-admittedly sloppy work of people not well known at a lab not highly regarded" (p325), is an unjustified slur on the lab where Cohn and Volkin (*Nature,* **167,** 483; 1951) pioneered on phosphate linkages in nucleic acids. Also in 1956, Fraenkel-Conrat, and Schramm, showed that tobacco mosaic virus RNA was by itself infective and carried all the information needed to make the virus. In 1960 (pp432-446) various efforts succeeded in establishing the existence of messenger RNA. However, in 1961, messenger RNA was upstaged by polyuridylic acid, and we learn (pp475-479) that Nirenberg and Matthaei had never even heard of messenger RNA!

Judson, to some extent, follows Watson's style be describing personal characteristics of superstars. The less ostentatious scientists come off second best. Judson says (p581): "what Pardee lacked, perhaps, was the knack of generalization". For "generalization", read "self-glorification". Stent, who is a sort of Louella Parsons of molecular biology, is quoted (p405) as saying that Pardee is its "Douanier Rousseau", an analogy that I found strange. Pardee is probably more of an orginator (like Chagall?) than a primitive. Judson's preoccupation with the personal life of his luminaries sometimes becomes excessively chatty. For example (p283):

> "On 6 December 1954, Stent wrote to Brenner, saying, in part:
>
> Dearest Sydneyboy!
>
> The Lwoffs have just left, and I have a few moments between cocktail-parties to dash off a couple of lines, so that there'll be news from us awaiting you when you make your triumphant return to the Rand. Ta ever so for your Oxonian and Cantabrian letters which both Inga and your serviteur devoured with the greatest of that old gusto. Boy do we miss you here! You simply *must* come back to Berkeley. In future letters, I hope we can discuss in more detail just what we can do to bring you and your gang for an extended stay back to Bagdad-by-the-Bay . . . .
>
> So, Wolfgang Amadeus von und zu Witwatersrand, receive thousands of amitiés from your ever-faithful
>
> Inga and Gunther"

But Judson does well with prolonged and detailed scientific descriptions in a variety of fields, especially crystallography and protein structure. His book will be widely read by scientists; and of course, the handful who are apotheosised by it will love it, as will their admirers.

Throughout the book, one becomes aware of a race between two schools — on one hand, deductions made by molecular geneticists and theorists, and on the other, the staunch empiricism of biochemists. The fine structure of the gene was solved by Ingram's demonstration in 1956 that glutamic acid at the sixth residue of ß haemoglobin was replaceable by mutation to either valine or lysine. Benzer's approach to this was by genetic analysis of rII mutants in bacteriophage T4, which reached some kind of a peak in a six-page fold-out that was inserted in *Proc. natn Acad.Sci. U.S.A.* in 1961. The inexorable progress of biochemistry brought the tangible emergence of transfer RNA, soon following its prediction by Crick's brilliant adaptor hypothesis. On p341, an account of the genesis of the RNA cloverleaf structure would have been welcome. The formula for glucose on p378 is incorrect.

In this book, some of the prominent scientists whose personalities were familiarised by Jim Watson, continue to cavort as they did in *The Double Helix*, and are joined by other performers. We are spared few details, even unto the length of the hairs in Brenner's eyebrows (up to three inches). But Judson's careful and sympathetic account of the life of Monod, developed at great length, is good reading.

Will *The Eighth Day of Creation* be studied as history, read as a novel, or used as a textbook? My own feeling is that the history of molecular biology deserves, for documentary purposes, a more dispassionate and even-handed treatment by someone who will undertake a task comparable in detail to that of Judson.

Thomas H. Jukes is in the Department of Biophysics and Medical Physics, University of California, Berkeley, California.

Special Offer - 16 issues for the price of 12 for orders received before December 31st 1979!

Trends in Pharmacological Sciences

Published in association with the International Union of Pharmacology

Trends in Pharmacological Sciences ('TIPS') is the new magazine for pharmacologists. It contains news, reviews, feature articles, and book reviews on all aspects of pharmacology and related disciplines. Written by acknowledged experts, the purpose of 'TIPS' is to enable researchers, teachers and students to inform themselves of major themes and developments.

The inaugural issue of 'TIPS' was published in April 1979 and has been widely praised for the interest and topicality of its articles and the attractiveness and clarity of its format. Regular monthly publication began in October.

A **special offer** is being made to all subscribers whose orders are received before December 31st. They will receive twelve issues published in 1980 plus the four issues published this year **for the same price as an annual subscription.** See below for details of price and ordering addresses.

'TIPS' is aimed at an international multidisciplinary market of academic, clinical and industrial pharmacologists. It embraces every major aspect of the field including basic and applied pharmacology, therapeutics, and toxicology.

A unique combination of scholarly innovation and imaginative enterprise, 'TIPS' is set to become the focal point for discussion of major themes in pharmacology - *SUBSCRIBE NOW AND SECURE THE BEST IN REVIEWS AND COMMENT UNTIL THE END OF 1980.*

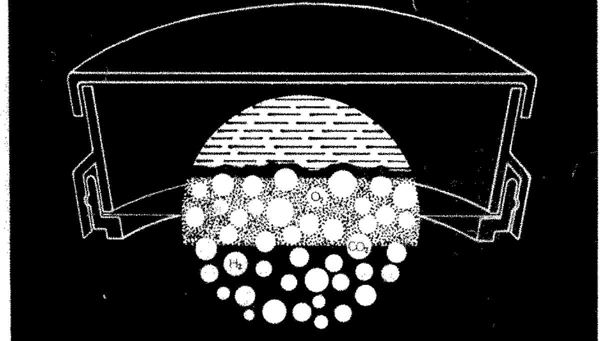
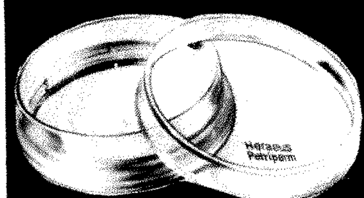
A new approach in tissue culture

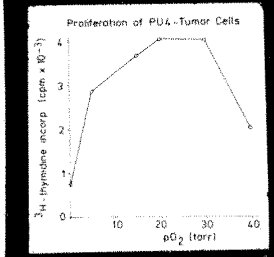




PETRIPERM
a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:
- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy.
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.



In the intact animal, the pH, and the partial pressure of both oxygen and CO_2 of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. PETRIPERM is the prerequisite for the precise control of pO_2, pCO_2 and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 µm thick membrane.

**Heraeus—

Switching of globin genes

Cellular and Molecular Regulation of Hemoglobin Switching. Edited by G. Stamatoyannopoulos and A.W. Nienhuis. Pp. 792. (Grune and Stratton: New York, San Francisco and London, 1979.) $68.50.

THIS multi-authored book contains the proceedings of a conference held in June 1978 which aimed to review the areas of haemoglobin synthesis and red blood cell differentiation pertinent to developmental and physiological 'switching' of globin genes. The sheer volume of information in this book is staggering, and it is difficult in this review to do justice to all 48 articles. The style of presentation was left to individual authors and I found most papers very readable, with many contributors presenting their work in a more general, and generous, way than is usually found in the literature. One disappointing feature of the book is that it lacks a general overview of the type previously published for the meeting (see *Cell,* **15**, 307-315; 1978), and this leaves the reader to judge how far the field had progressed in 1978.

The book is divided into three main sections covering the changes in haemoglobin synthesis during development, haemoglobin switching and erythroid differentiation, and the molecular biology of globin genes. The first article by Weatherall clearly describes what is known about the genetics of human disorders that are characterised by the persistent synthesis of fetal haemoglobins after birth, and subsequent papers examine human fetal globin chain synthesis *in vivo.* Using animal models for studying the 'switching' of haemoglobins, the concept of stress erythropoiesis in baboons (De Simone *et al.*) and in sheep (Wood *et al.*) is introduced, leading to a series of articles describing the controls of haemoglobin synthesis in these model systems.

Attention is next focused on erythroid precursor cells with articles showing the hormone influence on differentiation and the differences between stem cells isolated from bone marrow and peripheral blood. Highlights of this section include a review by Eaves on erythropoietic differentiation. Rapid progress has been made in the culture of haemoglobin-producing cells *in vitro* and Nienhuis shows examples of this in an article on 'switching' in cultured sheep stem cells. Ingram proposes a provocative model to explain the possible effect of various chemical inducers on the metabolic events in Friend cells which leads to differentiation and the subsequent accumulation of globin mRNA species.

The final section of the book deals exclusively with the molecular layout of globin genes and includes an elegant description of mouse β-globin gene arrangement by Leder and an explicit guide to cloning genomic DNA in λ bacteriophage by Lacey *et al.* A series of three papers show how the human globin gene map looked in 1978. Globin mRNA is well reviewed in a series of articles covering such topics as sequence, modification, processing, and developmental changes. In the final part entitled "Control of globin gene expression", Weintraub proposes how classes of nuclear protein may interact with DNA in active genes conferring the conformation required for specific expression; this is the only paper to mention nucleosomes. Young *et al.* show the use of DNase I for probing active globin genes in fetal and anaemic sheep, their results indicating quite different mechanisms for gene activation and deactivation. Finally Deisseroth and Hendrick explain their results with cell fusion and Anderson *et al.* report the progress in trying to use cell microinjection as a potential assay for those elusive regulatory factors.

I feel sure researchers in the haemoglobin field will find this a valuable reference book. It also offers much to the clinician attempting to understand the newer areas of biology.

Graham Cowling

Graham Cowling is in the Department of Biophysics, King's College, University of London, UK.

Rotating stars

Theory of Rotating Stars. By J.-L. Tassoul. Pp. 506. (Princeton University Press: Princeton, New Jersey, and Guildford, UK, 1979.) Hardback £25; paperback £9.40.

ROTATION pervades the domains of astronomy at every level: planetary, stellar, galactic, and beyond. This book is devoted to the stellar level. The study, both observational and theoretical, of rotating stars is a growing speciality among astrophysicists. No other reference work in the subject even attempts the breadth of coverage presented in this book. It will be heavily used, not only by specialists, but also by non-specialists looking for a concise and authoritative picture of the status of one or another branch of the subject. The explantions are sufficiently clear and self-contained that it could serve as a graduate-level text.

The first two chapters summarise the historical development and observational background, emphasising the problems confronting theory, thereby motivating the choices of theoretical questions found in the remainder of the book. These are followed by a chapter on hydrodynamics, specialised to the conditions prevailing in stars. This is an especially important chapter. It underlies the rest of the book in the sense that virtually all questions subsequently addressed are formulated as hydrodynamical problems. It is not an easy matter to develop hydrodynamics in one chapter (in fact, certain special aspects of the subject, stability theory in particular, are developed in chapter six). Tassoul does a very good job in my opinion, both in explaining the subject matter and in guiding the reader to the literature. For example, specialists in stellar hydrodynamics have had an unfortunate tendency to ignore the large and related body of material in geophysical hydrodynamics. Tassoul is careful to make the appropriate references to the geophysical literature.

Chapters four to seven are very much preparatory, theoretical, and hydrodynamical in nature, covering steady-state models of rotating axisymmetric stars, techniques for constructing them, techniques for studying their stability, and some results of a general character regarding their stability. Chapter four, on permanent rotations, collects a number of classical results on the nature of the allowable rotating configurations, many of which appear only in older, relatively inaccessible texts or articles. Some are given in detail, like Hamy's proof that a centrally condensed barotrope cannot be stratified on concentric spheroids. Others are only stated, like Lichtenstein's theorem that a uniformly rotating and uniformly dense self-gravitating mass possesses an equatorial plane of symmetry. In chapter five, a number of approximate methods, perturbation and numerical, for constructing rotating configurations, are described. Chapter six is devoted to an up-to-date description of stability techniques, some of which find applications in chapter seven to obtain limitations on the allowable distributions of angular momentum.

The discussion of specific subspecialties begins with chapter eight (on meridional circulation) and concludes with chapter sixteen (on rotation in close binaries). In between there are chapters on the Sun's differential rotation, on the distinctions between uniformly and differentially rotating models, on the questions of collapse and fission, on a closer examination of the relation of the models to observations, on white-dwarf stars, on oscillation and stability properties, and on magnetic fields in rotating stars.

There exist some books and review articles covering some of these narrow areas in depth, and others covering broader areas superficially. Until the appearance of this book, there existed no reference attempting broad coverage in depth. Tassoul has filled this gap with a high standard of scholarship. In some respects, his book has the appearance of a series of review articles on a variety of subspecialties, but it is much more. It is an account of the field, uniform in style and scholarship, and further unified by a particular viewpoint. The viewpoint is definitely from the theoretical side, and observational astronomers may find it uncongenial, although Tassoul has made consistent efforts to relate theory to observation.

The literature review is impressive. It must have required reading and digesting an enormous number of articles covering widely differing scientific viewpoints. The conclusions of these articles are not simply reported, but are compared, criticised, and, in some cases, synthesised. For example, in chapter eight on meridional circulation, a section of about ten pages is devoted to a critical review of the assumptions underlying the subject. Five principal assumptions are isolated and collected at the beginning of the section, and then examined one by one. This degree of thoroughness does not make light reading, but is certainly useful to anyone wanting to understand the subject in depth. Other examples of this kind of critical examination of assumptions, less formally organised, are found throughout the book.

Another, closely related, function of the book is to summarise the work of others. This is especially helpful when competing theories are summarised side by side. This is done, for example, in the cases of theories of the Sun's differential rotation (chapter 9), of the collapse and fission of protostars (chapter 11), and of the β-cepheid variables (chapter 14). It is inevitable in summarising conclusions from many subspecialties that some erroneous assertions must appear. But in reading with particular care the summaries of those areas I think I understand, I am principally impressed by their accuracy. The errors do not seem damaging. They are insignificant in comparison with the assistance the summaries provide to the otherwise unguided reader.

Nobody is perfect. Tassoul omits some topics that are currently exciting a lot of interest. The scope of a book like this does have to be limited in some way, and Tassoul's stated principle for doing so is to consider only topics of long standing from Newtonian (as opposed to general relativistic) mechanics. He does not discuss the widely accepted picture of pulsars as rotating neutron stars (because the subject is not of sufficiently long standing?) or X-ray binaries and black holes. He has apparently decided to direct attention only to those problems that have settled down to the point that their formulations (if not their solutions) are clear and not likely to change before the book gets into print. One can sympathise with this decision while recognising that it makes the book duller than it would otherwise be. It would not have required a deep excursion into the theory of general relativity to present some of the current work and at least provide references. There is a precedent for this in the book, in the chapter on close binaries: the more questionable points are not discussed in detail, but references are given.

And there are some errors. I noted a succession of minor errors in chapter 6 on oscillations and stability. For example, the definition of stability given on page 116 fails to apply to conservative systems, as it requires departures from the unperturbed state to die away with time, rather than merely remain small. Next, the commutivity of the operators of Lagrangian pertubation and of material derivative is presented only in the linear approximation (page 119), whereas it holds quite generally. Perhaps this omission is excusable, as this is the presentation given in the usual reference, but it has the effect of propagating an erroneous impression. On page 122 it is asserted that the free boundary of a fluid mass is defined by the condition that the pressure vanish there. It is possible to get away with such a definition without making mistakes, at least in a number of special cases, but it is not the right mathematical description of the physical situation. The free boundary is defined as the mathematical (or topological) boundary of the set where the density is positive, and the vanishing of the pressure there is a physical boundary condition, not a definition.

This frequency of errors is not typical. I noted a few more through the book, of the same degree of seriousness as those above: annoying, but not paralysing. Doubtless there are others I missed, but my net impression remains that the number of inaccuracies is remarkably small considering the scope of the book, and their negative contribution is negligible in comparison with the overall, positive contribution.

References are collected at the end of each chapter, related to sections within that chapter, and partially annotated, thus giving some guidance to the reader. There is an index of names, apparently quite complete, and an index of subjects, which I found incomplete.

This book should, and I feel sure will, become the standard reference for the subject matter covered. Anyone involved in the subject of rotating stars will simplify his life by having a copy on his shelf.

Norman R. Lebovitz

Norman R. Lebovitz is Professor of Applied Mathematics at the University of Chicago, Illinois.

Chinese chemistry and chemical engineering

Chemistry and Chemical Engineering in the People's Republic of China. Edited by John D. Baldeschwieler. Pp, 266. (American Chemical Society: Washington, DC, 1979.) Hardback $15; paperback $9.50.

THIS book is the report of a US delegation of chemists and chemical engineers which travelled widely in central and northeastern regions of the People's Republic of China during May–June, 1978. It is perhaps the most informative survey of chemical activities yet available. Chinese science, in modern form, began in the first half of this century and although at a rather preliminary level, seemed to be progressing slowly before 1965. In the following ten years, the influence of the 'gang-of-four' and its Cultural Revolution was serious, halting progress and destroying morale. Premier Chou-En-lai had talked in 1975 of the four modernisations, including science and technology, but only after the removal of the gang-of-four in 1976 could his principles be applied. In 1977–78 plans for re-orientations were announced by Chairman Hua Kuo-feng, and later by Vice-Premier Teng Hsiao p'ing, and Fang Yi, head of the Commission on Science and Technology, then gave full details of a seven-year programme aided at achieving parity with other big nations by the turn of the century.

There are three main sectors, the Chinese Academy of Sciences (CAS), the universities (under the Ministry of Education), and the Ministry of Production, all being coordinated and controlled by the Commission for Science and Technology (CST), whose head Fang Yi is a Vice-Premier, a Vice-President of the CAS, and a member of the Political Bureau. A few centres are run in whole or part by the provincial Government, and special divisions of the CST are dealing with energy, communications and industrial technology.

The CAS in Peking was greatly weakened in the Cultural Revolution, but its status has now been restored, and there are already some 90 research institutes across the country, covering the main fields of science, and branches of the CAS in Shanghai, Czechuan, Sinkiang and elsewhere. There are, at present, 14 Institutes for different aspects of chemistry (300–1000 staff) and scientists themselves are again playing a greater part in formulating policy, rather than the Revolutionary Committees, many old directors having been re-instated. The Chinese Academy of Medical Sciences (CAMS) has 13 Institutes in Peking and Shanghai, and links with hospitals and with the pharmaceutical industry. Research training courses for university graduates now operate in some of the Institutes.

Peak quality in chromatography!

Pharmacia Columns are designed to exploit to the full the separation properties of your bed material.

- High resolution
- Ease of performance and maintenance
- Inertness
- Aqueous or solvent work
- Low or medium pressure
- Fast and easy sample application
- Reversed flow and recycling
- Compatible with a wide range of accessories for systems building
- Reliability

The quality of your work deserves the quality of Pharmacia Columns.

BRITISH COUNCIL COURSE

Monitoring the side effects of Pesticide use

8–19 April 1980 in Ascot

The Director of Studies will be Dr G N J Le Patourel in association with Professor M J Way, both of the Department of Zoology and Applied Entomology at Imperial College, Silwood Park, situated near Ascot, in Berkshire.

The course, which is residential, aims to bring together experts involved in research, development, conservation and administration from relevant research institutes and other organisations, who have a common interest in the safety of new and existing pesticides and with the monitoring of hazards associated with their use.

The course is designed to be of interest to those in industry, government service or academic institutions who are undertaking research or who have responsibility for designing or operating monitoring programmes to assess environmental safety hazards associated with pesticide use.

Information and forms for registration may be obtained from local Representatives of the British Council or Director Courses Department, The British Council, 65 Davies Street, London W1Y 2AA.

Application forms must be received in London by 1 December, 1979.

There are vacancies for 25 members.

Fee including full pension accommodation £370.

THE MACMILLAN DICTIONARY OF ASTRONOMY

Valerie Illingworth

This Macmillan Dictionary reflects the explosive growth of astronomy in the last few years. It contains up-to-date references to the many exciting developments and discoveries that have been made in these years as well as to established theories.
It is a concise and comprehensive work; fully cross-referenced, it contains illustrations and diagrams making it the ideal personal reference book for both the specialist and the interested layman.

M MACMILLAN PRESS

The universities, too, were very disturbed by the gang-of-four. Foremost for chemistry, perhaps, are Peking, Shanghai (Futan), Kirin and Canton, and for engineering Peking (Tsinghua) and Shanghai. Student numbers have increased considerably in the past two years. Entrance examinations have been re-introduced, giving first priority to intellectual ability, and there is to be far less time for political instruction. There is still a serious shortage of textbooks. The student/staff ratio is very low (average about 2.7), very different from that in European or American universities. Chemistry courses have been lengthened to four years, in which some mathematics, physics and applied science is included. Equipment for teaching is fairly good. Unfortunately, the effects of the Cultural Revolution were to create a sort of vacuum in the trained teaching staff, for the older members who had received training in Europe or America are now old or retired, and the middle-aged and younger groups were sent out to the Communes and have become dispersed. In spite of the intrinsic ability of the Chinese people, this shortage of adequate staff may not be corrected for many years. A few universities are trying to start advanced research training, but no degrees are to be given yet. Contractual applied research or actual production previously carried out in some universities has almost entirely ceased.

The pattern of industrial technology and research is complex, and under a combination of central and provincial control, as in the petroleum and chemical industries, and in the extensive research on catalysts. Scientific staff for the Taching oil development are mostly trained at the Peking Petroleum Institute, and the Harbin Petroleum Research Institute is still largely controlled by the provincial Government. Chinese students, after training, are prepared to be sent wherever their country needs them.

As might be expected, much of the current science and technology in China is directed towards practical needs. Impressive work is in progress on pharmaceuticals, especially those extracted from indigenous plants, traditionally used as medicinals; and on the synthesis of natural products and nucleic acids. These include peptides, hormones, prostaglandins, antibiotics and some anti-cancer and anti-bronchitis reagents. Much of this work is done in the Institutes of Organic Chemistry, Biochemistry and Materia Medica in Shanghai, and those of Materia Medica and Chemistry in Peking. The synthesis of insulin in the Institute of Biochemistry, Shanghai, some years ago was a famous achievement. Production of polymers, mostly the best known classes, has made good progress, with extensive research on improved catalysts for polymerisation. The Peking Institute of Chemistry has a large division on polymer research. There and in other Institutes, new fluoropolymers, crown-ether type polymers, and others with functional groups having pharmacological or other useful properities, are being studied.

Excellent work is being done in the Institute for Ceramics and Metallurgy, Shanghai, including the growth of single crystals, ferrites, ceramics for the electronic industry and for high temperature equipment, diamonds, and crystals with special optical and electrical properties. Research in the petroleum and petrochemical fields is concentrated in Institutes at or near refineries or industrial complexes in some of the major cities. There is conventional work on the evaluation of crude oils, catalytic cracking and reforming of fuels, catalysts, lubricating oils and additives, engine testing and adhesives. Close contact between the Institutes and production plants is maintained. The manufacture of petro-protein using yeast is being explored, the products being tested as animal feedstuffs.

Rare earth ores are abundant in China, the elements being separated by ion exchange or through complexing reagents. Their possible use for the coating of fluorescence tubes, as converters of X-rays into visible radiation in medical equipment, and for catalysts is being explored.

By contrast, there is relatively little work on organometallic chemistry, molecular spectroscopy in relation to structure, quantum and theoretical chemistry, or reaction mechanisms and kinetics. Isotopes such as $^{18}0$, ^{15}N, ^{13}C are being produced for labelling and tracer work, high-energy physics has not yet begun. T present computer facilities are limited. With a few exceptions, there is still shortage of newer physical instruments and techniques for structural determination and analysis, such as those for nuclear magnetic resonance, X-ray crystallography, mass spectgromatry, electron or Mossbauer spectroscopy. There is much admirable home-made equipment of a less sophisticated kind, such as chromatographs. Work with lasers is still at an early stage, and studies with molecular beams have not yet started. All this is consistent with the policy of dealing with the more urgently practical applicatrions first, but this situation may change quickly.

This book gives details of all places visited, names of scientific workers, charts of the organisation of science and technology, and the state of scientific information services in China. As regards both factual comments and the opinions expressed, it agrees closely with reports of Fellows of the Royal Society who have visited China in recent years. It is an admirable account for all interested in Chinese chemistry and chemical engineering. **H.W. Thompson**

Sir Harold Thompson was formerly Professor of Chemistry at the University of Oxford and Foreign Secretary of the Royal Society. He has visited China three times: in 1962 and 1974 with delegations from the Royal Society, and earlier this year on behalf of the Great Britain-China Centre, of whose Executive Committee he is Chairman.

Trying to comprehend

The Nature of the Physical Universe: The 1976 Nobel Conference. Edited by D. Huff and O. Prewett. (Wiley-Interscience: New York and Chichester, UK, 1979). £12.75.

THIS volume collects together six lectures given at the twelth conference supported by the Nobel Foundation at Gustavus Adolphus College, Minnesota. They are concerned with our understanding of the nature of the physical Universe, and with man's place in it. The level is intended to benefit an audience of intelligent laymen.

The first four lectures, given by scientists, are breathtaking in their scope. Viki Weisskopf begins at the microscopic level with the question "What is an Elementary Particle?". He quickly traces the history of man's exploration of matter, describing the energy level systems appropriate for atoms, for nuclei, and for nucleons. With such differing depths of exploration before us, a firm reply to this question is obviously difficult, but his final answer is in terms of "*conditional elementarity*", the idea being that we can speak of elementary particles or not, only when we specify the energy resolution of our observations. The question whether quarks themselves may have structure is thus left open, for future research to settle. It is indeed a most pertinent question, now that we recognise 15 varieties of quark (5 flavours, each with 3 'colours'), since the discovery of the upsilon particle in 1978. At present, we have no evidence for any structure, or finite size, for these quarks, but this situation may change when we can experiment at much higher energies and momentum transfers.

This story is then taken on by Murray Gell-Mann, who speaks about the new quantum number of 'colour', and about the gauge theory which has been built on it, known today as quantum chromodynamics (QCD). But there are also the 'leptons', the electron and its heavier counterparts, the μ and τ leptons, and the three neutrinos corresponding to them. Gell-Mann describes the programme of unification, recently successful in uniting electromagnetic and weak interactions to form the "electro-weak interaction"; with its next goal the ronic forces with them, his grand design has been our most cherished dream, seem to be rather close to it". ion would change suddenly, if were found to have substructure.

ve Weinberg asks "Is Nature mple?". His emphasis is on symmetries, not only the symmetries of space-time known from our daily life, but also the so-called internal symmetries, associated with charge, flavours, colour, and so on. For these latter, he introduces the notion of gauge symmetries, which imply the existence of gauge fields, with corresponding quanta; these gauge symmetries then govern the interaction of the gauge quanta with quarks and leptons. In this sense it is the gauge symmetry of colour which requires the existence of a gluon field, the gauge field for colour, which carries colour itself.

Most of the internal symmetries which we have known in elementary particle physics have turned out to be only approximately true, and, as a consequence of gauge theories, Weinberg now believes that "all these approximate symmetries can be, and in fact are being, understood as dynamical accidents". His remark is made specifically for flavour symmetries and it is a remarkable conclusion today, when one recalls what a great step forward the SU(3) unitary symmetry seemed to be in the mid-1960s. This has been a remarkable change in our point of view, which has dawned on most of us only quite recently, long after Weinberg's lecture. His remark applies even to parity conservation, allowing the possibility that particles with left-hand spin may have physical properties different from their right-hand counterparts. Weinberg concludes that "it is probably too early to try to think of drawing any philosophical lesson from discoveries in physics".

Fred Hoyle's lecture is concerned with the development of the Universe, right from the first moments of the 'Big Bang'. His emphasis is on the abundances of elements today, and on the conditions which must have existed to give rise to them. He draws our attention to the observation of simple organic molecules embedded in grains of meteoric dust, seeing in them a possible interstellar origin for life, arising even before our own Solar System formed. He traces out the nature of our chemical environment and leads us to the question "What does this tell us about the long-term future of our species?" These constraints imply a number of unpleasant conclusions concerning our very immediate future, for we cannot expect "to enjoy the great luxury of living in a hydrocarbon era" for many more generations. However, if population limitation were to come soon, and we could reach zero population growth, then "nothing concerning the future of our species would look unfavourable".

The last two lectures are rather philosophical in style. Stanley Jaki of Seton Hall University lectured under the heading "The Chaos of Scientific Cosmology". His remarks about its history interested the reviewer, as we scientists hear rather little concerning older theories about the Universe, refuted by later evidence. It is odd to hear the views once accepted as reasonable by eminent scientists whose names have become law in the areas of their own scientific success. However, it is not clear whether the chaos Professor Jaki is speaking of is the chaos of this history of cosmologies, or whether it is the chaos of matter within the Universe. In his view, "the primeval chaos of fundamental particles" is connected somehow with its unreliable mathematical underpinning, unreliable because Gödel's incompleteness theorem removes any hope of demonstrating the consistency of any such mathematical system within itself. So he advises caution concerning any beliefs about scientific cosmologies or any implications they may suggest for Mankind.

The final lecture was given by Hilary Putnam, who discussed three areas lying outside present-day science: the domains of objective values, of freedom of choice, and of rationality. He rejects the notion that ethics are the result of instinct or conditioning. He considers whether our impression of free will results only from Chance but concludes that we have so little understanding of probability that this line of thought can offer no hope for any enlightment. His opinion is that the selection pressures of evolution cannot account in full for the development of ethics and rationality, an understandable view with which we will all have much sympathy. On the other hand, our ability to develop Science, and to comprehend and control our Universe by discovering physical laws and understanding how to use them for prediction, could well have arisen as a by-product of natural selection, in the reviewer's opinion. The situation does not call for the existence of any selection pressures directed specifically towards scientific activity. Also, our development of Science is not the result of testing random hypotheses, nor is it the end result in a chain of mathematical logic, the possibilities considered by Professor Putnam; it lies somewhere between, guided by the mind's ability to react to needs, to see analogies, and so to relate things apparently rather different, all characteristics which may simply be by-products of the survival value of rationality.

To this reviewer, the contrast between the earlier and the later lectures in this series illustrates well the enormous gulf between scientists and philosophers today, a gulf which is probably as large as it has ever been. Scientists have clarified large areas of human experience, in their analysis of the functioning and the forces of the physical world around us. This has enabled us to plan and to build, and to control great forces, and no doubt these abilities will grow much greater in the future. So it seems to a scientist a strange question, to be asked what fundamental justification there can be for the validity of his work, when he sees its products operating successfully and developing further, day by day. On the other hand, as Weinberg indicates, most physicists today would consider it unwise to seek within Science the proper basis for philosophy. Science is pragmatic, and we have seen enormous changes of viewpoint within the period of our own lives. All that was established before remains valid through these changes, of course, while becoming only a small part of the greater whole which has subsequently emerged and which continues to emerge. The relationships between scientific truths, and the perspective in our view of them, naturally continue to change as the picture becomes both larger and more detailed. As further knowledge is added, the patterns we see develop and come to have different meanings, and we must change our views in accord with them. Perhaps all this says is that we scientists no longer consider ourselves to be natural *philosophers*, seeking an absolute and final understanding, but see ourselves simply as men trying to comprehend, and to use for further discovery and comprehension, the forces acting within our Universe.

R.H. Dalitz

R. H. Dalitz is Royal Society Research Professor in Theoretical Physics in the University of Oxford, UK.

Errata

- In the review of *Ludwig Wittgenstein: Remarks on the Foundations of Mathematics* (see *Nature*, **281**, 242; 1979), point 39 in the series of quotations from the work should have read:

> 39. The proposition '$a = a$', '$p \supset p$' ['If p, then p'], 'The word "Bismarck" has 8 letters', 'There is no such thing as reddish-green', are all obvious and are propositions about essence: what have they in common? They are evidently each of a different kind and differently used. The last but one is the most like an empirical proposition. And it can understandably be called a synthetic *a priori* proposition.
>
> It can be said: unless you put the series of numbers and the series of letters side by side, you cannot know how many letters the word has.

Also, Michael Dummett, the reviewer, is Wykeham Professor of Logic in the University of Oxford, UK.

- In the review of *Handbook of Geochemistry* (see *Nature*, **281**, 242; 1979), line 6 should have read "Part 5 is also by far the largest to appear,".

APPOINTMENTS VACANT

IMPERIAL COLLEGE
(University of London)
DEPARTMENT OF CHEMISTRY

LECTURESHIP IN INORGANIC CHEMISTRY

Applications are invited for the above post. Candidates should have active research experience and will be expected to develop a vigorous research programme in a field of inorganic chemistry which has sound prospects for future development. Salary in the Lecturer scale £5,073 — £9,732 inclusive of London Allowance.

Applications with curriculum vitae, giving research interests and the names of three referees, to Sir Geoffrey Wilkinson, Department of Chemistry, Imperial College, London SW7 2AY, from whom further particulars may be obtained. Closing date for applications January 31st 1980. 3472(A)

THE CAMPDEN FOOD PRESERVATION RESEARCH ASSOCIATION

GRADUATE ENGINEER

to work on a variety of instrumentation and control problems. In the first instance the work would be primarily concerned with microprocessor applications for the Food Industry.

Industrial or research experience would be an advantage, not necessarily in food technology.

Salary in accordance with age and experience on Research Officer scale within the range £3,048 to £5,316 p.a.

Job specification and application form on request to the Secretary-General, The Campden Food Preservation Research Association, Chipping Campden, Glos. GL55 6LD. 3437(A)

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOLOGICAL SCIENCES

LECTURESHIP

Applications are invited from geneticists, microbiologists, molecular biologists and biochemists for the post of Lecturer in the Department of Biological Sciences.

Experience of nucleic acid or microbial genetic techniques would be an advantage though not essential.

Salary scale £4,333 to £8,992 (under review).

Applications (6 copies, or if posted overseas 1 copy) including a Curriculum Vitae and the names and addresses of two referees should be sent by 23 October 1979 to the Secretary, The University, Dundee, DD1 4HN from whom further details of the post can be obtained. Please quote Ref: EST/82/3/79. 3422(A)

Head of Pharmaceutical Development

We wish to appoint a Head of Pharmaceutical Development at our Pharmaceutical Research Laboratories. The person appointed will be a qualified pharmacist with several years' experience in the industry and will take charge of a young and successful department of some 20 staff which is responsible for the development of new drug formulations, the supply of test compounds for human and animal trials and basic pharmaceutical research.

This is a key senior appointment in the Research Group of a major international company and will appeal to a creative pharmacist with a proven record of success in research, who is now seeking a greater challenge. Salary and other benefits – including a company car – will reflect the importance of the position.

The modern and exceptionally well-equipped laboratories are situated in the new city of Milton Keynes in a pleasant part of North Buckinghamshire.

Scientists, male or female, whose experience meets our requirements are invited to send a brief curriculum vitae to:

Dr. J. D. Coombes, Research Director,
Hoechst Pharmaceutical Research Laboratories,
Walton Manor, Walton, Milton Keynes MK7 7AJ.

UNIVERSITY OF WESTERN AUSTRALIA
Perth

LECTURESHIP IN PHYSICAL AND INORGANIC CHEMISTRY

Applications for the above position in th Department of Physical and Inorgani Chemistry are invited from suitabl qualified persons. The appointee will b required to share in the genera undergraduate teaching responsibilities o the Department, to lecture in his fields o specialisation at undergraduate an postgraduate levels and to carry ou research for which time and good facilitie are available.

The School of Chemistry occupies a we equipped building with machine, electroni and glass-blowing workshops. A wid range of equipment for physical measure ments is available, and the University ha good computing facilities. The staff of th Department consists of seventeen member and there are 35 postgraduate an postdoctoral research workers. Furthe details of the Department's curren research interests and publications ar available on request from the Head.

The current salary range for a Lecture is: $A16,291 to $A21,401 per annum Benefits include superannuation similar t FSSU, fares to Perth for appointee an dependent family, removal allowanc study leave and long service leave an housing loan scheme.

Applications in duplicate stating fu personal particulars, qualifications an experience should reach the Actin Staffing Officer, University of Wester Australia, Nedlands, 6009, Wester Australia, by 10th November, 197 Candidates should request three referees t write immediately to the Acting Staffin Officer. 3478(A)

THE UNIVERSITY OF SYDNEY

LECTURESHIP IN BIOLOGY

Applications are sought from persons wi a research interest in any field of vertebra biology. Preference may be given applicants in the fields of development biology, physiology, behaviour, ecology evolution. Appointee will be expected carry out and supervise research in his her special field, to participate in teachi of vertebrate biology and to contribute general teaching programme of the Scho

The position is expected to be filled by probationary appointment of three yea capable of leading to tenure but if all t University's requirements for tenure a deemed to be satisfactorily met tenure m be granted at the time of appointment.

Salary range: $A16,291 to $21,401 p.

Applications including curriculum vita list of publications and names of th referees by 9 November 1979 to Registr University of Sydney, NSW 20 Australia, from whom further informati available. Information also available fr the Association of Commonwea Universities (Appts), 36 Gordon Squa London WC1H 0PF. 3476(A

Editor of Nature

Applications are invited from those wishing their names to be considered for this appointment, which will become vacant at the end of this year.

A brief account of past career, qualifications and experience considered relevant should be sent in writing to:

nature

The Publishing Director,
Macmillan Journals Limited,
4 Little Essex Street,
LONDON WC2R 3LF

3456(A)

JOHN INNES INSTITUTE

Applications are invited for a three year temporary appointment in the

DEPARTMENT OF GENETICS

To collaborate with a group working on the genetics of the nitrogen fixing symbiosis between *Rhizobium* spp. and legumes by complementing their genetical studies with the physical analysis of plasmids which carry genes essential for nodulation and nitrogen fixation. Although the group's work will continue, this appointment is to initiate physical studies on plasmids and this particular aspect is expected to be completed by the end of the three year period. Further particulars obtainable from Professor D.A. Hopwood, Head of the Department of Genetics.

Applicants should have a first or upper second class honours degree in biochemistry, microbiology, molecular biology or genetics, with at least two years' post-qualifying experience, but preferably PhD and relevant postdoctoral experience. Appointment as Higher Scientific Officer, salary w.e.f. 1.1.80 £5,097 to £6,737). Starting salary epending on experience. Non-contributory superannuation.

Applications, quoting reference GEN/33, giving full particulars and the names of two referees, should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich, NR4 7UH, not later than th November, 1979. 3469(A)

ST HELIER HOSPITAL
Carshalton, Surrey
POST DOCTORAL RESEARCH ASSISTANT

Required with experience in Immunology or Enzymes. Small department with 3 other workers.

Reply with Curriculum Vitae and names of three referees to Dr E.L. Rhodes at above hospital by 27th October.

3467(A)

BLOOD GROUP REFERENCE LABORATORY
SENIOR SCIENTIFIC OFFICER

The Blood Group Reference Laboratory is a Central Reference Laboratory for the National Blood Transfusion Service. This laboratory is a substantial producer of blood grouping reagents of human and animal origin. In the near future significant changes in manufacturing procedures are foreseen with changes in processing, the use of hyperimmune donors and *in vitro* cultures of lymphocytes as new sources of material. It is anticipated that this laboratory will be increasingly involved in monitoring quality of grouping reagents from a variety of external sources.

A Senior Scientific Officer is sought to take charge of all aspects of production and quality control of blood grouping reagents and to be responsible for new developments and research in these areas. Salary: £8,182 to £10,097 (increase pending) plus £502 L.W. Further information may be obtained from Dr A.M. Holburn, 01 730 2152.

Application in writing with details of experience and the names of two referees to: Mis K Lomas, Blood Group Reference Laboratory, Gatliff Road, off Ebury Bridge Road, London SW1W 8QJ.

3440(A)

THE CAMPDEN FOOD Preservation Research Association, Chipping Campden, Glos GL55 6LD, requires a food scientist, food technologist or home economist to head the quality appraisal team in its Department of Agriculture and Quality. The successful candidate will be enthusiastic, have qualities of leadership and get on well with people. Salary in the Research Officer (£3,048 to £5,316) or Senior Research Officer grade (£4,884 to £7,260). Further details and application form from the Secretary-General at the above address. 3436(A)

WELSH NATIONAL SCHOOL OF MEDICINE
(University of Wales)
DEPARTMENT OF SURGERY

Applications are invited from post-doctoral scientists with wide experience and proven capability in the field of cellular immunology for the post of Lecturer in the above department at Heath Park, Cardiff. Special expertise in the field of cancer or gastrointestinal immunology would be advantageous. The successful candidate will direct the scientific side of a clinically orientated research laboratory, working in close collaboration with clinicians with similar interests. The appointment will be for 3 years in the first instance with possible renewal thereafter to be discussed with interested candidates.

Salary on the scale for Non-Clinical Lecturers (£4,333 to £8,922 per annum, under review); starting point dependent upon qualifications and experience. U.S.S. available.

Further particulars available from the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff, CF4 4XN, to whom applications should be submitted 3 weeks from the date of the appearance of this advertisement.

3444(A)

KINGSTON POLYTECHNIC
SCHOOL OF GEOLOGY
SLIDE MAKER

To be responsible for all thin section preparation for the School, together with such ancillary techniques and preparation of polished ore specimens, specimen slabbing, and polishing and preparation of grain slides.

Experience essential: Advanced Technician Certificate an advantage. T3/4 £4,470-£5,457 inclusive.

Application forms from Assistant Registrar (Personnel), Kingston Polytechnic, Penrhyn Road, Kingston upon Thames KT1 2EE. Tel: 01-549 1366.

3441(A)

STANFORD UNIVERSITY
GEOCHEMIST —PETROLOGIST

The Department of Geology in the School of Earth Sciences invites applications for a faculty position beginning September, 1980. Areas of interest include (but are not limited to) geochemical processes in the crust and mantle of the earth including isotope geochemistry, thermodynamics, kinetics, element distribution and phase equilibria studies. Teaching responsibilities might include graduate and undergraduate courses in geochemistry and igneous petrology. Level of appointment is open, but we are particularly interested in a creative young person, with a well-established record in research.

Applications should include (1) a resume of education, professional experience, and published research; (2) a brief statement of plans for future research, and (3) the names of 4 referees. Send to: Prof. J.G. Liou, Department of Geology, Stanford University, Stanford, CA 94305, by December 1st, 1979. Stanford University is an equal-opportunity/affirmative-action employer. W329(A)

BLOOD GROUP REFERENCE LABORATORY
SCIENTIFIC OFFICER

This laboratory is a Central Reference Laboratory for the National Blood Transfusion Service. A graduate is sought for research and development of techniques for the detection of antibodies to neutrophil leucocytes. Experience in immunology or immunohaematology desirable.

Application in writing with details of experience and the names of two referees to: Miss K. Lomas, Blood Group Reference Laboratory, Gatliff Road, off Ebury Bridge Road, London SW1W 8QJ.

3439(A)

Murdoch University

PERTH, WESTERN AUSTRALIA

DEANSHIP OF THE SCHOOL OF VETERINARY STUDIES

(Ref: EN0007)

Applications are invited from suitably qualified persons for appointment to the position of Dean of the School of Veterinary Studies which has become vacant owing to the appointment of Professor R H Dunlop to the University of Minnesota, U.S.A. The position is available from 1 February 1980 or as soon thereafter as possible.

The qualifications expected of applicants include a higher degree, substantial experience in veterinary education and eligibility for registration under the Western Australian Veterinary Practitioners Act. The successful applicant will be appointed both as Dean of the School for a period of five years, which may be renewed at the discretion of the governing body and as a permanent full-time professor in the applicant's particular discipline.

Although the School is an integrated unit, it is administered as two divisions. Veterinary Biology is headed by Professor J. Mc. Howell and Applied Veterinary Medicine by Professor M.E. Nairn. R.G. Wales is the Professor of Physiology, R.A. Swan is the Professor of Veterinary Clinical Studies, W.T. Clark is the Professor of Small Animal Medicine and Surgery and the present establishment for academic staff is 39. There is an entry quota of forty-eight students per year. The initial developmental phase of the School is now completed and the first major graduation of Bachelor of Veterinary Medicine and Surgery students will take place early in 1980.

SALARY AND CONDITIONS The salary is at present $A34,119 per annum. Conditions of appointment include superannuation similar to F.S.S.U., long service leave, access to outside studies programme, payment of fares to Perth for appointee and dependent family, removal and settling-in allowances and house purchase scheme.

PROCEDURE FOR APPLICATION There is no prescribed application form, but TWO COMPLETE SETS of detailed applications, quoting the appropriate reference number, including full personal particulars, details of tertiary qualifications career history with description of posts held, area of special competence and interest, research completed or currently being undertaken, membership of professional institutions or societies and positions of responsibility in these, list of relevant material published by the applicant, when available to take up appointment if offered and the names and addresses of three professional referees should reach the Personnel Officer, Murdoch University, Murdoch, Western Australia 6150 by *5 November 1979.*

Applicants resident in the United Kingdom, Europe or Africa at the time of application should also forward ONE further copy to:—

The Secretary General
Association of Commonwealth Universities (Appts)
36 Gordon Square
London WC1H 0PF

Further general information on the University and the Conditions of appointment and facilities is available from the Personnel Officer, Murdoch University or from the Association of Commonwealth Universities. 3455(A)

THE POLYTECHNIC — HUDDERSFIELD

RE-ADVERTISEMENT

(Previous applicants need not re-apply)

DEPARTMENT OF LIFE SCIENCES

PRINCIPAL LECTURER, SENIOR LECTURER OR LECTURER II — HUMAN ECOLOGY

Ref: ACA/343/A/N

Preference will be given to candidates with teaching and/or industrial experience and a proven research record and possessing a first degree in a Biological subject and a higher degree in Agriculture or Biological resource management. Experience of developing countries particularly in tropical resources would be advantageous.

Staff are expected to undertake activities, including research, in addition to teaching duties.

Salary	PL	£7,680 — £8,523 (Bar) — £9,639
	SL	£6,597 — £7,710 (Bar) — £8,253
	LII	£4,770 — £7,149 per annum

Further details and application forms, which should be returned by 26th October, 1979 from the Personnel Office, the Polytechnic, Queensgate, Huddersfield, HD1 3DH (Telephone 0484 22288 Ext 2223). Please quote the relevant reference number. 3463(A)

UNIVERSITY OF RHODESIA

PROFESSOR AND HEAD OF DEPARTMENT OF ZOOLOGY

Candidates should hold a doctorate in Zoology, should have experience in research and teaching at university level, and should have held a senior university appointment in Zoology.

LECTURESHIP/SENIOR LECTURESHIP IN GEOLOGY

Applicants must hold, at least, an honours degree in Geology, with experience in metamorphic and/or sedimentology and coal geology.

Salary scales and conditions of service: Professor £9,162×345 — 10,872 p.a. Senior Lecturer £6,662×259 — 7,439 ×274 — 8,809 p.a. Lecturer Grade I £6,043×227 — 6,951 p.a. Lecturer Grade II £3,731×196 — 4,711×227 — 5,846 p.a. (approximate conversions from Zimbabwe-Rhodesia $ to £ sterling at 7/9/79.)

Permanent Pensionable Terms: Family passages and allowance towards transport of effects on appointment. Installation loan of up to half of one year's salary if required. Unfurnished University accommodation guaranteed for a period of at least three years for persons recruited from outside Zimbabwe-Rhodesia. Sabbatical leave and biennial visits with travel allowances. Superannuation and medical aid schemes.

Short-Term Contracts: Family passages and allowance towards transport of effects. Assistance with accommodation for persons recruited from outside Zimbabwe-Rhodesia.

Applications (6 copies) should give full personal particulars (including full name, place and date of birth, etc.), qualifications, experience, publications, present salary, date of availability, and names and addresses of three referees, and should be sent to the Appointments Officer (Staff), University of Rhodesia, PO Box MP 167, Mount Pleasant, Salisbury, Zimbabwe-Rhodesia. Please state clearly for which post application is being made. Overseas applicants should send an additional copy of their application to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom conditions of appointment can be obtained.

Closing date for applications — *15 November, 1979.*

IMPORTANT British subjects considering applying for posts in Zimbabwe-Rhodesia are urged to consult the Foreign and Commonwealth Office (tel: 01-233 4995) or their nearest British Consular Office. 3426(A)

THE UNIVERSITY OF MANITOBA

invites applications for the position of

PROFESSOR AND HEAD of the DEPARTMENT OF STATISTICS

Currently there are twelve faculty members in the Department which offers undergraduate and graduate programs, and the laboratories and facilities provide a stimulating environment for research and teaching.

Salary will be appropriate to the qualifications of the appointee. The 1979-80 floor for full professors is $29,743.

Canadian citizens, landed immigrants and others eligible for employment in Canada at the time of application are especially encouraged to apply.

Applications should be made as soon as possible, giving curriculum vitae, publication list and names of three referees to Dr C C Bigelow, Dean, Faculty of Science, University of Manitoba, Winnipeg, Manitoba, R3T 2N2.

W417(A)

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified persons seeking appointment to the following positions.

RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

DEPARTMENT OF ENVIRONMENTAL BIOLOGY

FELLOW

The Department wishes to make a tenured appointment in experimental community ecology. Applicants should be experienced in dynamic aspects of community ecology (plant demography or plant populatior biology). Familiarity with theoretica community ecology is desirable but we seek applicants who will devise experiments tc test key concepts in community theory. It is desirable that such a research programme should complement the Department's interests in physiological plant ecology.

Closing date: 16 November, 1979.

DEPARTMENT OF GENETICS

FELLOW IN MOLECULAR GENETICS

The research project for which this post ha been established will require the successfu applicant to collaborate with Dr B. Rolf on work involving the genetic manipulation of nitrogen fixation genes i *Rhizobium*. According applicants shoul have completed at least 5 years relevan postdoctoral research and have experienc of a wide range of recombinant DN techniques.

Closing date: 16 November, 1979.

RESEARCH SCHOOL OF PHYSICAL SCIENCES

DEPARTMENT OF MATHEMATICS

RESEARCH FELLOW

Current departmental research interes include number theory, group theor (computational group theory, Burnsic problems, groups of prime-power orde and varieties), global analysis an harmonic analysis, ordinary differenti equations and control theory, foundatio and set theory, linear algebraic groups, ar combinatorics, but applications will considered in any field of moder mathematics.

Closing date: 10 November, 1979.

Conditions of appointment: Salaries w be in accordance with qualifications ar experience within the range: Fello $A18,990 to $25,441; Research Fello $A16,291 to $21,265 per annum. Prese exchange rate $A1 = UK 50p.

Appointment as Research Fellow Mathematics is for three years with t possibility of extension to five years. Fellow is appointed for five years in the fi instance with the possibility reappointment after review to age 65.

Reasonable appointment expenses a paid. Superannuation benefits a available for applicants who are eligible contribute. Assistance with findi accommodation is provided for appointee from outside Canberra. T University reserves the right not to make appointment or to make an appointme by invitation at any time.

Prospective applicants should fi obtain further particulars from t Association of Commonweal Universities (Appts), 36 Gordon Squa London WC1H 0PF. 3429(A

INSTITUT FÜR PHYSIOLOGISC Chemie der Universität, Hambu Application invited for two positions. Technische/r Angestellte/r and 1 W Angestellte/r). Research in cellu differentiation, cell membranes, pro synthesis. Letter of application to Prof Gebhard Koch, Physiologisch-Chemisc Institut, Abteilung Molekular-biolo Grindelallee 117, 2000 Hamburg Germany. W427(A

Centre for Overseas Pest Research, Kensington, London

Field Entomologist

The Centre for Overseas Pest Research seeks to help developing countries by devising efficient pest control techniques.

The successful candidate will be involved in work overseas on projects concerned with research surveys, control and training activities related to major crop pest problems.

The person appointed can expect to spend a considerable proportion of time on overseas tours, which are likely to be in Eastern Africa for the first few years.

Applicants, usually under 32 years of age, should have a good honours degree in a biological subject, with some training in entomology, and at least 4 years' postgraduate experience, preferably including several years' overseas experience working on major pest problems in developing countries.

Appointment as Senior Scientific Officer £6,655 – £8,640 (to become £7,110 – £9,485 from 1.1.80) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 5 November 1979) write to Mr H Woodman, Centre for Overseas Pest Research, College House, Wrights Lane, London W8 5SJ.

Please quote ref: SA/54/JA.

Ministry of Agriculture, Fisheries and Food,
Radiobiological Laboratory, Lowestoft

Scientists/Engineers

Each licensed nuclear site disposing of liquid radioactive wastes in the environment requires a discharge assessment before MAFF, as authorising department, can decide on the permissible level of discharge. All new sites require such an assessment, and discharges from existing sites require periodic examination.

Assess the effect of radioactive wastes on the environment

The successful candidate will advise senior staff of permissible discharge limits on the basis of information obtained from assessing the relationship between the discharge rate and the extent of radiation affecting individuals or critical groups within the population. This calculation will also involve estimating the collective dose to the population as a whole. In addition, the work will include developing and applying new methods for evaluating waste restrictions, maintaining a close liaison with research staff and participating in national and international working groups.

Candidates, normally aged under 30, should have a good honours degree in physics, chemistry or engineering. At least 2 years' postgraduate experience essential. Some experience in OR environments advantageous.

Appointment as Higher Scientific Officer. Starting salary (according to qualifications and experience) within the range £4,725 – £6,210 (to become £5,095 – £6,735 from 1.1.80). Promotion prospects. Non-contributory pension scheme.

Assist with radiological control programmes

The successful candidate will join a team responsible for the design, development, execution and interpretation of environmental monitoring programmes. In addition to playing a full role in this work, the scientist appointed will assist with the collection, preparation, interpretation and analysis of information, to ensure that existing and future monitoring programmes are run effectively and productively. Field studies, including work on research vessels will be an important aspect of the job.

Candidates, normally aged under 27, should have a good honours degree or equivalent in physics, chemistry or biology. An ability to handle data and apply techniques of numerical analysis essential.

Appointment as Scientific Officer. Starting salary (according to qualifications and experience) within the range £3,285 – £5,085 (to become £3,590 – £5,485 from 1.1.80). Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 2 November 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours).

THE UNIVERSITY OF NEW ENGLAND

Armidale, New South Wales

DEPARTMENT OF AGRONOMY & SOIL SCIENCE

LECTURESHIP IN SOIL SCIENCE

The Division of Soil Science within the Department of Agronomy and Soil Science is responsible for undergraduate teaching of Soil Science in the Faculties of Rural Science, Resource Management, Arts and Economic Studies. Research and postgraduate training within the Division is concerned with various aspects of soil chemistry, biology and physics in relation to soil genesis, fertility and management.

The appointee will lecture and organise practical classes in introductory Soil Science courses. Supervision of advanced student projects will also be required. An appointee is sought in the areas of Soil Biology and/or Soil Management (soil conservation, pollution, reclamation, etc.) and preference will be given to persons in either of these areas having training in Soil Science and experience in teaching and research. The appointee is expected to take up duties in February 1980.

Salary: $A16,291 – $21,402 p.a. Assistance will be given with travel and removals.

Applicants in the UK, Europe and America should forward their applications, and ask their referees to forward their reports, without delay to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom conditions of appointment can be obtained. An additional copy of application only should be sent to the Staff Officer, University of New England, Armidale, NSW 2351, Australia, quoting Position No. 424.

Applications close *31 October, 1979.* 3477(A)

UNIVERSITY OF DUBLIN
Trinity College

RESEARCH ASSISTANT IN GEOLOGY

A Research Assistant is required for the newly established Applied Geology Unit at Trinity College Dublin. The successful candidate will join a joint Trinity College/Geological Survey of Ireland team making an integrated stratigraphical study of offshore Mesozoic basins based upon material obtained from petroleum exploration wells. The post, available in January 1980, will be for a period of 3 to 4 years.

Salary scale: £3,174 to £4,286 p.a. Appointment will be made at a point commensurate with the qualifications and experience to date of the successful candidate.

Applicants, who should have a degree in Geology and interests in Micropalaeontological and palynological techniques, should send a curriculum vitae and the names of two referees to Professor C.H. Holland, Department of Geology, Trinity College, Dublin 2, to arrive by November 12th 1979. 3445(A)

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a post doctoral research post (MRC funded) to study the regulation of the synthesis of anaerobic enzymes in *Escherichia coli*. Ideally the successful candidate will have had some previous experience of the techniques of DNA sequencing and/or *in vitro* protein synthesis.

The appointment is tenable for one year initially, with the possibility of extension for a further two years at a starting salary of up to £5,193 (under review) depending upon experience.

Informal enquiries may be made to Dr. B. A. Haddock, Department of Biochemistry, University of Dundee, Dundee DD1 4HN (telephone 0382 23181 ext. 551).

Applications including curriculum vitae and the names and addresses of two referees should be sent to The Secretary, The University, Dundee DD1 4HN quoting Reference EST/84/79X as soon as possible. 3423(A)

UNIVERSITY OF OXFORD

DEPARTMENT OF AGRICULTURAL SCIENCE

POST DOCTORAL RESEARCH ASSISTANT

Applications are invited for a three year project funded by ARC to work with Dr B C Loughman on the metabolism of phenoxyacetic acid derivatives in higher plants and possible relevance to selective action of these and other herbicides. The isolation of hydroxylating, glycosylating and polymer forming enzyme systems and investigation of possible mechanisms of control by light and other factors will be major aspects of the work.

The starting date will be 1 January, 1980 and the salary in the Grade 1A range (£4,333 to £7,521). Applicants, who should be familiar with enzymological methods and have experience with plant material, should write to the Administrator, Department of Agricultural Science, Parks Road, Oxford OX1 3PF enclosing curriculum vitae and names of two referees by 31 October. 3475(A)

Appointment as ofessor is to retiring age (at present 65), th an option to retire after the age of 60. Salary will be not less than $A34,119 per num. Current exchange rates are 1 = $US1.12 = 50p.

Applications are invited from persons in y field of mathematics. This is a position voted to research and graduate training d there are no obligatory undergraduate ching responsibilities.

The University reserves the right not to ke an appointment or to make an pointment by invitation at any time.

Intending applicants should, in the first tance, obtain the further particulars m the Association of Commonwealth iversities (Appts), 36 Gordon Square, ndon WC1H 0PF. Closing date: 1 April, 80. 3428(A)

OVERSEAS DEVELOPMENT

KNOW-HOW-vital to developing countries

Chief Extension Officer
Senior Research Officer Sudan

The Southern Region Agriculture Development Project is entering a considerably expanded 4 year phase with multi-donor financing and the British Government has undertaken to provide a substantial number of senior and supporting staff for the project.

The Chief Extension Officer will head the Rural Services Division, Juba and be responsible for extension and nutrition services, crop marketing, support media activities and training. Appropriate degree with a minimum of 10 years relevant post-graduate experience required with sound knowledge of extension in small-holder agriculture in Africa and some experience in operation of credit schemes and marketing.

The Senior Research Officer will lead the Crop Research Unit, Yei and be responsible for the planning, execution and supervision of the research programme concentrating on the important food crops of higher rainfall areas; establishment of pest, disease and weed control service; development of improved farming systems. Appropriate degree with minimum of 10 years experience in agricultural research and development in tropical areas required with emphasis on food crop production in rainfall conditions.

Applicants should be citizen of the United Kingdom aged 35 to 50 years and should be prepared for extensive travel within the region.

Salary in senior range above £10,000 pa (UK taxable) plus variable tax free overseas allowances £1,040 to £3,175 pa £425 to £850 pa depending on marital status.

Appointments for 2 years with home leave after 12 months. Further posts of Entomologist, Farm Management Specialist, Senior Extension Officer and Agronomist will arise as housing becomes available over the next year.

These posts are wholly financed by the British Government under Britain's programme of aid to the developing countries. Other benefits normally include paid leave, free family passages, childrens education allowances and holiday visits, free accommodation and medical attention.

For full details and application form please apply, quoting ref (331X) stating post concerned, and giving details of age, qualifications and experience to:—

Appointments Officer,

ASSISTANT PROFESSOR

We have an opening at the assistant professor level in the
DEPARTMENT OF MICROBIOLOGY

at the

UNIVERSITY OF BRITISH COLUMBIA

We are seeking an individual with training in any aspect of molecular biology. Responsibilities would include teaching at the undergraduate level, direction of graduate students and development of a strong research program. There are several active molecular biology groups at U.B.C. with which the individual may interact.

Please send curriculum vitae and the names of three referees to Dr J.J.R. Campbell, Professor and Head, Department of Microbiology, University of BC, 2075 Wesbrook Mall, Vancouver, BC V6T 1W5. W420(A)

ROCHE RESEARCH INSTITUTE OF MARINE PHARMACOLOGY

BIOCHEMIST

POST-DOCTORAL FELLOW

The Roche Research Institute of Marine Pharmacology has been established at Dee Why, N.S.W., to carry out multidisciplinary research into the biology, microbiology, pharmacology and chemistry of a wide range of natural products from marine organisms.

A biochemist is required to investigate biosynthetic pathways in several eukaryotic microorganisms, including algae. A knowledge of molecular genetics, chemistry and biochemistry of isoprenoids and techniques for studying membrane-bound enzyme systems would be helpful. Experience with HPLC separation techniques would be valuable.

This is a post-doctoral position, initially for 1 year with possible extension to 2 years.

Salary will be negotiated according to experience. Assistance with removal expenses is envisaged.

Applications and names and addresses of three referees should be sent to:

The Director, Roche Research Institute of Marine Pharmacology, PO Box 255, DEE WHY. AUSTRALIA. 2099.

Applications close 31st October, 1979.

British Museum (Natural History) London

Head of Palynology Section

The British Museum (Natural History) is an institution for taxonomic research and an educational focal point for the public. The main aim of the research is to produce definitive accounts of the world's animals, plants and minerals as well as the preservation of an extensive collection of fossils. There are comprehensive library, computing and laboratory facilities.

The successful candidate will, as Head of the Palynology Section, be responsible for the curation and development of the research collections. The work will also involve assessing the effect of applying pollen characters to taxonomic problems, answering enquiries relating to palynology and supervising junior staff. There will be opportunities for limited involvement in general taxonomy and the possibility of field-work both in this country and abroad.

Candidates, normally aged under 32, should have a good honours degree or equivalent in Botany or closely related subject. At least 2 years' postgraduate experience in taxonomy is essential and practical experience of taxonomic palynology is highly desirable.

Appointment as Senior Scientific Officer £6,655 – £8,640 or Higher Scientific Officer £5,505 – £6,990 (to become £7,110 – £9,485 and £5,875 – £7,515 respectively from 1.1.80). Level of appointment and starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further information and an application form (to be returned by 9 November 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote ref: SB/65/DK.*

(University of Reading)
CHEMISTRY
DEPARTMENT

A graduate is required to work for thre years on the effect of heat on the protein and enzymes of human milk. The wor involves undertaking a detailed study of th kinetics of their heat denaturation an relating their results to the effect o pasteurisation treatments on human milk

Qualifications: First or Upper Secon Class Honours degree in biochemistry o food science. An opportunity exists for suitable candidate to register for a highe degree.

Appointment, for a limited period o only three years, will be as Scientifi Officer; salary scale £3,289 to £5,08 (£3,591 to £5,486 from 1.1.80). Non contributory superannuation.

Application forms obtainable from th Secretary, NIRD, Shinfield, Reading RG 9AT. Quote reference: 79/32. 3350(A)

UNIVERSITY OF NEWCASTLE UPON TYNE

BIOCHEMISTRY RESEARCH DEMONSTRATORSHIP

Applications are invited for the post of

DEMONSTRATOR

in the Department of Biochemistry from candidates who possess, or have submitted for, a PhD in Biochemistry, for a period of up to three years, tenable from 1st January, 1980. Research projects currently in progress include membrane transport of nucleic acid precursors (Professor K. Burton), acquisition and modification of enzyme conformation, and immunochemistry of monocyte surface (Professor R.H. Paine), DNA repair and genetic recombination (Dr P.T. Emmerson), triglyceride and lipoprotein metabolism (Dr M.P. Rogers), enzymology of resistance to antibiotics (Dr R. Virden), lactose transport and bioenergetics (Dr I.C. West) and hormonal control of enzyme activity (Dr S.J. Yeaman). Duties will also include teaching (approximately 90 hours per year) by lectures, tutorials and practical classes.

Salary will be at an appropriate point on the Grade 1B (Bar) scale £3,775 to £5,488 per annum according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from the Senior Assistant Registrar (F.P.) The University, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU, with whom applications (2 copies), giving the names and addresses of three referees, should be lodged as soon as possible.

PRODUCT REGISTRATION OFFICER

Pfizer Central Research, which this year was granted a Queen's Award for technological achievement, is part of a multinational organisation engaged in the research, development, manufacture and marketing of a wide range of human medicinal and animal health products.

Our Product Registration Department which is responsible for advising on the requirements of regulatory authorities throughout Europe, and for obtaining approval to undertake clinical studies on field trials, and subsequently, marketing of new human and veterinary drugs arising from our research laboratories both in the U.K. and U.S.A. now needs an additional Product Registration Officer.

The person appointed to this post will probably be in his/her late twenties or early thirties, have a degree in a science-based discipline, with ideally a post-graduate qualification and several years experience in registration work of both human and veterinary products. He/she will participate in all stages of the progression of a number of development candidates and compile the documentation necessary for regulatory submissions. In time extensive interaction with regulatory agencies and other Pfizer personnel in Europe will be required thus providing considerable scope for individual responsibility.

The starting salary will reflect qualifications and experience and in addition to excellent career prospects there is good bonus potential. Pension, death benefit and salary continuance schemes are in operation and there is generous assistance with re-location expenses to a pleasant coastal/rural area of East Kent.

Flexible hours are worked and the social/recreational facilities are first class.

3457(A)

Pfizer

Applications giving brief details of age, qualifications and experience should be sent to:

D.W. Sells, Personnel Manager, Pfizer Central Research, Sandwich, Kent.

1979

COMMONWEALTH AGRICULTURAL BUREAUX

Vacancy for

SCIENTIFIC INFORMATION OFFICER

at the

COMMONWEALTH BUREAU OF ANIMAL HEALTH

Central Veterinary Laboratory, New Haw, Weybridge, Surrey.

General information. The work of the Bureau is to collect and make available through its publications *The Veterinary Bulletin* and *Index Veterinarius* and by magnetic tape services, information relating to all aspects of veterinary science.

Main duties. The duties include searching scientific periodicals, indexing articles, preparing English-language abstracts for the monthly journal *The Veterinary Bulletin*, editorial work, dealing with enquiries and preparing reviews and bibliographies.

Qualifications. A qualification in information science or an appropriate biological science is required, plus a knowledge of European and Slavonic languages or a willingness to learn languages.

Salary. In the scale £3,289 to £6,211 per annum plus an Outer London Weighting allowance of £325 per annum, plus a compensatory allowance (taxable but not superannuable) of 3.3% to offset personal contribution to Superannuation Scheme — part-time appointment *pro rata*. Starting salary according to qualifications, experience and age.

Application forms and full particulars from the Executive Director, Commonwealth Agricultural Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN, to whom completed applications (in duplicate) should be sent by 30 November 1979. 3474(A)

MICROBIOLOGY

A regular tenure track position as an Assistant or Associate Professor is available commencing as soon as possible for an M.D. or a PhD with a minimum of two years postdoctoral training in microbial physiology or in infectious disease.

Send curriculum vitae and names of three referees to: Dr David Eidinger, Head, Department of Microbiology, University of Saskatchewan, Saskatoon, Saskatchewan, Canada S7N 0W0. Closing date for receipt of applications is November 30, 1979. W431(A)

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE

(University of London)

DEPARTMENT OF PHARMACOLOGY

A JUNIOR TECHNICIAN

is required to assist with teaching and research work in the Department which is situated in the Clinical Sciences Building at the Royal Free Hospital in Pond Street, Hamstead. Experience in electron microscopy is essential.

Salary according to age and qualifications on Whitley Council Scales.

Application forms are available from the School Secretary, R.F.H.S.M., 8 Hunter Street, London, WC1N 1BP or telephone 01-837 5385 Ext. 10. Closing date: 26 October, 1979. 3464(A)

NEWCASTLE AREA HEALTH AUTHORITY (TEACHING)

NEWCASTLE GENERAL HOSPITAL MEDICAL LABORATORY

SCIENTIFIC OFFICER

required in Muscular Dystrophy Group Laboratories, Regional Neurological Centre. The successful applicant will assist with development of tissue culture techniques for study of muscle and nervous tissues as part of a research programme which involves several scientific disciplines. Experience of tissue culture and sterile techniques and a knowledge of electron microscopy an advantage. Candidates must be registered.

Further information from Mr J. J. Fulthorpe, Senior Chief MLSO, Tel: 0632-738811 extn 573.

Applications, with names and addresses of two professional referees, to Western Sector Administrator, Newcastle General Hospital, Newcastle upon Tyne NE4 6BE, by 19th October, 1979. 3424(A)

The Department of Geology and Geophysics of the State University of Utrecht has a temporary position (2 years) available for a

MINERALOGIST

He/She will work, in collaboration with a team of two other mineralogists, within the section of Petrology/ Mineralogy/Crystallography/Geochemistry/Pedology.

- take part in mineralogical courses (systematic mineralogy, mineralogical analytical methods). He/She will be mainly responsible for the organisation of new course on applied mineralogy.
- set up new research in applied mineralogy (mineralogical problems in industry, as for example the quality control of industrial minerals and processes for improvement of the properties of synthetic minerals).

Applicants must be mineralogists or chemist/chemical engineers with experience in applied mineralogy.

Salary depending on age and experience.

Information can be obtained from Prof. Dr. P. Hartman, Geological Institute, Garenmarkt 1b, Leiden, tel.: 071-148333 ext. 7337.

Candidates are requested to submit their application within three weeks to the Personnel Department, Geological Institute, Oude Gracht 320, Utrecht, The Netherlands. W424(A)

Max-Planck-Institut für Radioastronomie
Sonderforschungsbereich Radioastronomie

RESEARCH SCIENTIST or ENGINEER
MILLIMETER WAVELENGTH TECHNOLOGY

The MPIfR has a strong involvement in instrumental developments for radio astronomy in the millimeter and sub-millimeter wavelength range. It participates heavily in the construction and instrumentation of a 30-m diameter mm-telescope for the new French-German Institute for Radio Astronomy in the Millimeter Range (IRAM). Developments in the sub-millimeter region are underway in the fields of telescope and receiver design.

A physicist/electronics engineer is sought for the development of circuits in the frequency range 100-400 GHz and the integration of these to low-noise radio astronomy receivers. Knowledge and experience in the field of micro- or millimeter waves is required.

Momentarily the position is financed by the Deutsche Forschungsgemeinschaft and is time limited to end 1981. It is expected to continue the position after that date as a staff position at MPIfR. Salary according to the German government employees rules (BAT). Send application with résumé of education, experience and special interests

Director of Biology

G. D. Searle is a leading international pharmaceutical company with its main U.K. headquarters and research facilities at High Wycombe in Buckinghamshire.

Applications are invited for the position of Director of Biology from persons with qualifications and research experience in a Biological Science, preferably Pharmacology. This position reports to the Director of Research.

Responsibilities include directing the efforts of a number of groups of biological scientists working principally in the area of infectious diseases, immunology and tumour biology. In addition to drug testing programmes, studies on the mechanism of action of therapeutic agents and on the basic biology of the diseases are undertaken. The successful applicant must therefore have a broad view of biology and medicine, whilst being able to direct in depth studies in particular areas. The responsibilities also include management of the animal facilities, so direct experience is essential. Experience in supervision and administration of other licencees will be advantageous.

The groups within the Research Department are organised to encourage an interdisciplinary approach to most studies and past experience of this aspect within the Pharmaceutical Industry will be a strong recommendation. In addition evidence of managerial experience will be required.

This is a senior position, carrying a place on the Management Group of the Research Department, and the salary, which is negotiable, will reflect this seniority.

The benefits accompanying this post include: company car, relocation assistance, life insurance, contributory pension fund, private medical scheme, and sports and social club.

Applications should be addressed to Mr G. Jenkins, Personnel Manager, Searle Research & Development, G. D. Searle & Co. Ltd., Lane End Road, High Wycombe, Bucks (Tel. High Wycombe 21124, ext. 3374).

COURSES & CONFERENCES

UNIVERSITY COLLEGE DUBLIN
UNESCO — EEC
POST-GRADUATE COURSE IN TECHNIQUES IN ADVANCED INORGANIC CHEMISTRY

University College, Dublin in collaboration with the Irish National Commission for UNESCO, the Irish Department of Foreign Affairs and the Commission of the European Communities, Directorate-General for Development, Training Division wish to announce a Post-Graduate Course in Techniques in Advanced Inorganic Chemistry specially designed for students from developing countries who are presently employed in tertiary teaching or research institutes.

The Course will run from Tuesday, 5th August, 1980 until October 31st, 1980 and will commence with an intensive formal course of five weeks, involving lectures and laboratory work which will cover a wide range of topics such as advanced valence theory, molecular orbital methods, organometallic chemistry and diverse structural techniques (X-ray diffraction, electron diffraction, N.M.R. spectroscopy including ^{13}C N.M.R., magnetochemistry, E.S.R., IR.). The formal course will be followed by research work on a project in one of the above fields connected with the research interests of the present Inorganic Staff of the Department, which embrace Organometallic Chemistry, Coordination Chemistry and Theoretical Inorganic Chemistry.

Students applying for this course will be expected to have a Master's Degree. The language of instruction will be English.

Fellowships

A number of Irish Government sponsored scholarships are available to cover living costs. UNESCO will provide some fellowships to cover travel costs. The EEC will also provide fellowships to participants from ACP countries.

Applications

Application giving full details of the candidate's academic background, experience and names of referees should be made through the UNESCO National Commission of their respective country. Participants from ACP countries may apply to their own government for an EEC fellowship covering travel expenses to Ireland and course fees, including accommodation.

Completed applications should be sent to the Secretary, Chemistry Department, University College, Dublin, *before 31st December, 1979.*

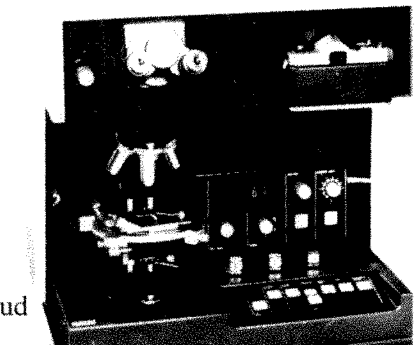
THE BARR & STROUD INTEGRATING MICRODENSITOMETER-DESIGNED TO REDUCE YOUR LABORATORY WORKLOAD



If you have a regular requirement for full quantitative cell information, it's worth checking out the Barr & Stroud GN5 Integrating Microdensitometer. With a scanning duration of only four seconds yet giving a 0.25 micron resolution, it brings speed and precision to cell preparation analysis.

The use of highest quality Leitz optics ensures reliability of results for even the smallest specimens. For histochemical and cytochemical studies, accuracy is better than ±1% over an optical density range from less than 0.1 to greater than 2.5.

Area measurement, electronic masking and narrowband illumination are just some of the other features which make this instrument a most attractive addition to your laboratory.

The GN5 Integrating Microdensitometer yields results with a speed and at a level of accuracy that far outstrips the standards that can be achieved by manual methods of study.

Designed in accordance with ergonomic principles, it's comfortable to work with too.

Start to reduce your laboratory workload by sending for full literature today. Use the journal reply system or, alternatively, contact us direct.

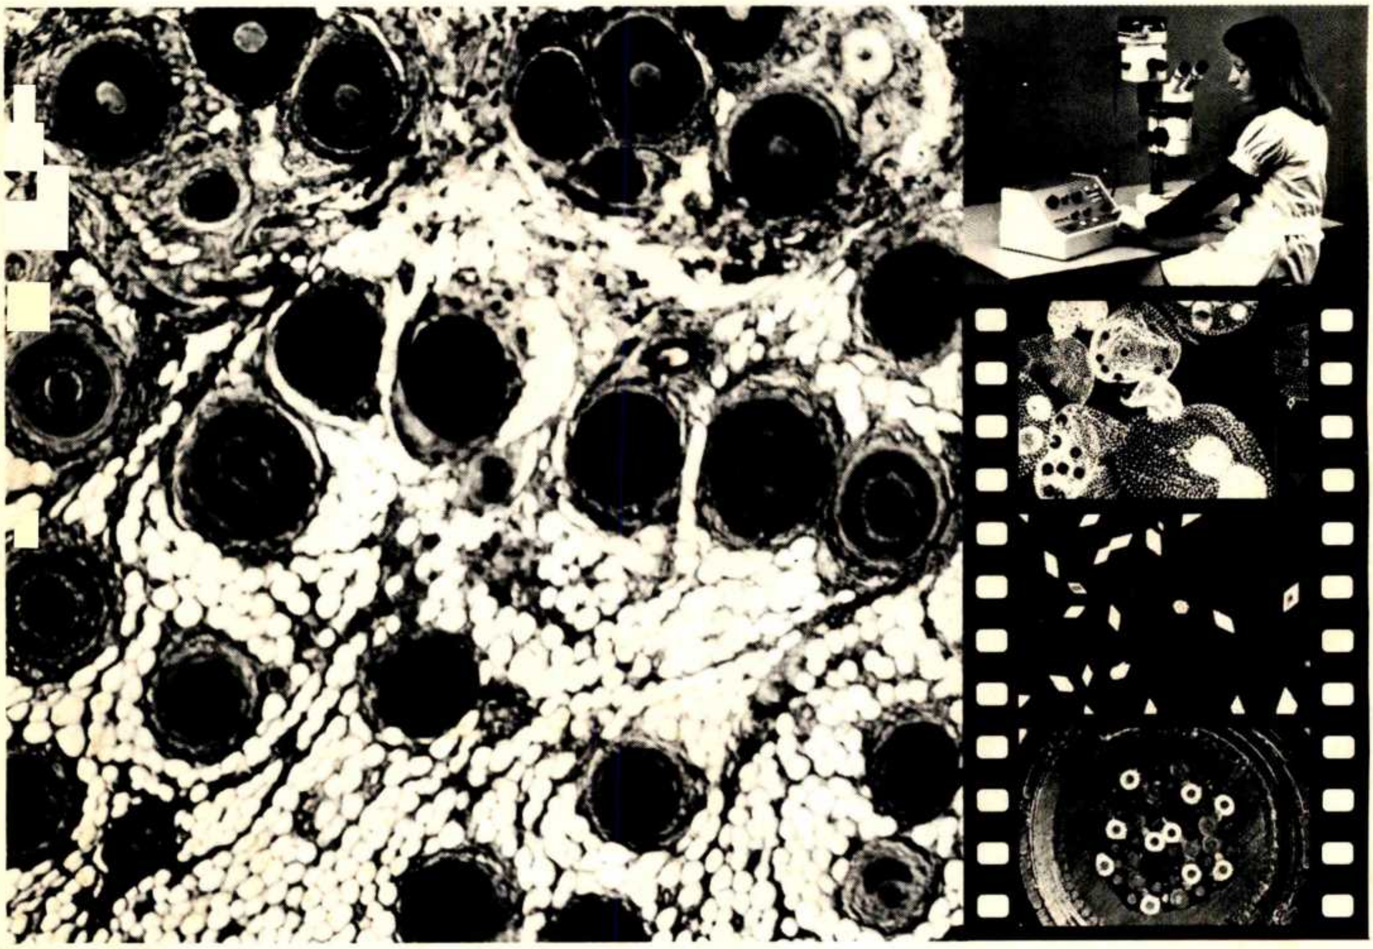
Professional photomicrographs in series.



With the new Wild MPS Microphoto System.

The new Photoautomat from Wild Heerbrugg represents a tremendous stride in the recording of microscopy specimens; an assurance of optimal exposure, superlative imaging and planned work. Everything has been automated: camera factor change between formats from 35 mm to 4 × 5''; super-sensitive exposure measurement for films from 5 to 43 DIN; exposure corresponding to film emulsion, with or without correction for reciprocity failure; film transport. Just concentrate on the specimen and on composing an expressive format. Press the button, and everything is taken care of. This doesn't mean that the Photoautomat jealously guards its secrets! The control unit displays not only the exposure time, but also the percentage of time elapsed, both of which can be influenced individually. That's how photomicrographs are made in series with the Wild MPS. Professional ones.

The various MPS systems for microscopes and stereomicroscopes are described in a colour leaflet. Ask for it.

The Science Dictionaries

Three useful and up-to-date works of reference intended not only for students, teachers and researchers but also for science journalists and the general reader.
Each book is designed for easy use – entries are arranged alphabetically and defined under the most common form of term, with synonyms in brackets. S.I. units are used throughout and all entries are thoroughly cross-referenced.

A Dictionary of Life Sciences

E. A. Martin

The recent trend to treat the biological /life sciences as a whole rather than divided into separate units is reflected in this concise dictionary which brings together in one volume all the main branches of zoology and botany. Selected terms in related fields of biochemistry, endocrinology, animal behaviour and palaeontology are also included. All major plant and animal classes are fully described as well as the more important orders, and common names of animals and plants are cross-referenced to their appropriate taxonomic groups.

1977 £5.95 392pp

A Dictionary of Earth Sciences

Stella E. Stiegeler

The subjects covered here include geophysics, structural geology, geomorphology, oceanography, stratigraphy, palaeontology, sedimentology, climatology, meteorology, soli science, cartography, mineralogy, petrology and surveying. The terms defined reflect the recent modification of traditional concepts and the resulting development of terminology in the earth sciences. In soil science, for example, a new system of classification is now in in use, with a completely new terminology for the soil orders.

1977 £5.95 320pp

A Dictionary of Physical Sciences

John Daintith

This book covers the main branches of physics, chemistry and astromony – from Abbe condenser to zoom lens and zwitterion. A selection of relevant terms from the related fields of electronics, computer science and mathematics is included. Full accounts are given of the properties and uses of the chemical elements and many of their compounds. All the chemical terminology used is that recommended by the International Union of Pure and Applied Chemistry.

1977 £5.95 352pp

To order a copy of any of these books, please send £5.95 plus 50p carriage to Technical Book Services, P.O. Box 79, Maidenhead, Berkshire SL6 2EG.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,** 1 (1975) and **264,** v, 11 Nov. (1976).

Evolutionary nucleotide replacements in DNA	*T.H. Jukes and J.L. King*	605
Localisation of the $^{G}\gamma$-, $^{A}\gamma$-, δ- and β-globin genes on the short arm of human chromosome 11	*A.J. Jeffreys, I.W. Craig and U. Francke*	606

Special Offer - 16 issues for the price of 12 for orders received before December 31st 1979!

Trends in Pharmacological Sciences

Published in association with the International Union of Pharmacology

Trends in Pharmacological Sciences ('TIPS') is the new magazine for pharmacologists. It contains news, reviews, feature articles, and book reviews on all aspects of pharmacology and related disciplines. Written by acknowledged experts, the purpose of 'TIPS' is to enable researchers, teachers and students to inform themselves of major themes and developments.

The inaugural issue of 'TIPS' was published in April 1979 and has been widely praised for the interest and topicality of its articles and the attractiveness and clarity of its format. Regular monthly publication began in October.

A **special offer** is being made to all subscribers whose orders are received before December 31st. They will receive twelve issues published in 1980 plus the four issues published this year **for the same price as an annual subscription.** See below for details of price and ordering addresses.

'TIPS' is aimed at an international multidisciplinary market of academic, clinical and industrial pharmacologists. It embraces every major aspect of the field including basic and applied pharmacology, therapeutics, and toxicology.

A unique combination of scholarly innovation and imaginative enterprise, 'TIPS' is set to become the focal point for discussion of major themes in pharmacology - *SUBSCRIBE NOW AND SECURE THE BEST IN REVIEWS AND COMMENT UNTIL THE END OF 1980.*

INDEXES

Annual Indexes are available for the years 1971-1978. The years' papers are listed by both author and subject.

Prices: UK: £5.00
Rest of World US$10.00

BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage):
UK £3.00 each, three for £8.00
Rest of World: US$6.00,
three for US$16.00.

To order, please send details and correct remittance to:

Nature,
Circulation Department,
Macmillan Journals Limited,
Brunel Road, Basingstoke,
Hampshire RG21 2XS, England

Cheques should be made payable to *Nature*. Payment may be made in any currency at the prevailing exchange rate.

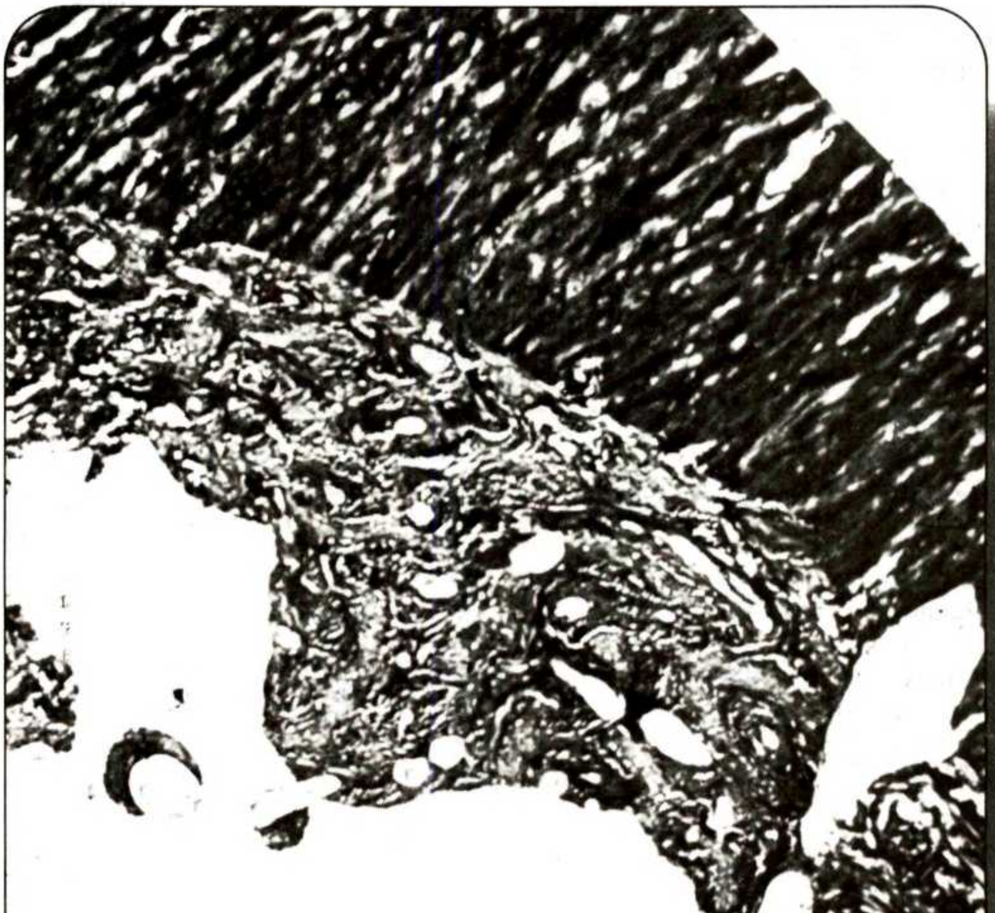
ELECTROPHORESIS AND RADIOIMMUNOASSAY
This month's new products feature focuses on radioimmunoassay and electrophoresis, and is found on p.xxi. Further information about these products can be obtained from the manufacturers, using our reader enquiry card service.

Helping nature to help itself

Internal fixation, or osteosynthesis, of bone by means of metal pins, screws, plates or wires, is often necessary to aid restoration of continuity and stability during healing of a fracture. However, the problems of rejection or encapsulation of such prostheses still remain.

One possible alternative to internal fixation is the use of a new bone structure developed jointly by the Dentistry Sub-Faculty of the Free University of Amsterdam and Philips Research Laboratories.

Tri-calcium phosphate powder, with a particle diameter of 2-3 microns, together with water and an oxygen-producing additive, was sintered at 1100-1400°C to produce a porous bio-degradable ceramic possessing the same compression strength as bony tissue. The procedure of treating the phosphate powder slurry and the subsequent sintering was chosen such that the porosity, or percentage of pores that de-

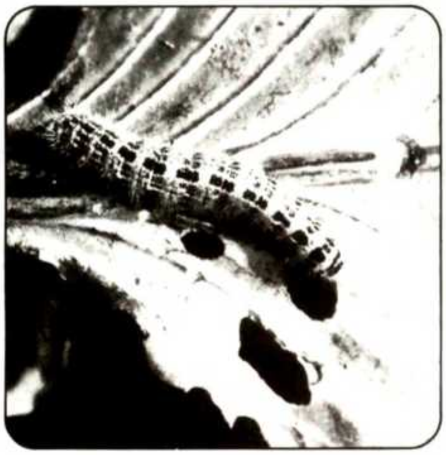


PHILIPS

termine tissue growth rate, can be accurately controlled, this enabling the 'artificial bone' to be gradually replaced by natural bone tissue.

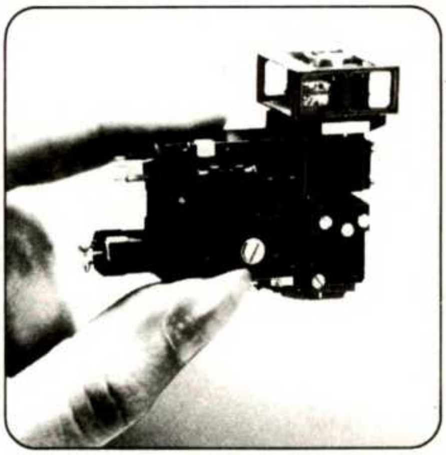
Laboratory studies on a rabbit-bone/artificial-bone join have so far produced very encouraging results. This photomicrograph, taken two months after implant, shows that a great deal of resorbtion has taken place. There is no evidence of any onset of rejection: no fibrous encapsulation tissue is found, and newly formed bone has been deposited directly to the ceramic implant. Osteoclast-like cells can be seen, as well as an osteon-like newly created pore complete with blood vessel.

And research is continuing, for we anticipate that further development will bring about important new possibilities in human bone surgery. Helping nature to help itself is one of our fields of research. Here are some others.



Crop protection. DIMILIN, a very selective insecticide made by Philips-Duphar, has recently been registered by the US Environmental Protection Agency for the control of the cotton boll weevil (Anthonomus grandis), which causes extensive damage to cotton crops. On cotton crops, for example, DIMILIN affects the boll weevil only and does not kill other insects. Unlike many other insecticides, adult insects are not killed. Since DIMILIN does not penetrate plant tissue, sucking insects will also not be affected. These characteristics form the basis of the unique selectivity of this insecticide. A further advantage of DIMILIN is, that only very small quantities are required to protect a crop: in cotton culture about 50 to 100 grams per hectare, applied six times per season.

Continuous subcutaneous infusion. A fully portable, battery-operated syringe driver developed by Pye Dynamics, a Philips company, has brought new hope to sufferers of certain kinds of inherited blood disease. Worn by affected children in a shoulder-harness, they are able to lead a normal life, while the life-supporting drug is continuously injected in the abdominal area.



Optical data storage. Philips' diode laser optical data storage system – the world's first – employs a micro-miniature read/write head, along with extremely high precision radial tracking and error-detection/correction systems, to record and/or retrieve 10^{10} data bits on a double-sided, 12-inch telluvium coated disk. An AlGaAs diode laser, contained in the head, produces sufficient pulsed light output to write, a 'beem', 1-μm data pits in the telluvium film, while an electro-optical system, also in the head, maintains an objective focusing accuracy of 1-μm with a radial tracking accuracy of 0.1-μm.

Wet bead diameter: 40—105 μm

Sephacryl®

the different medium for gel filtration

- **Faster separations: Sephacryl has speed and resolution to spare; separates proteins 5–10 times faster than conventional media.**
- **Faster packing: Sephacryl is pre-swollen, ready-to-use and packs fast.**

Use Sephacryl S-300 Superfine for separations up to an exclusion limit of 1.5 million for globular proteins; ideal for serum proteins. Use Sephacryl S-200 Superfine up to an exclusion limit of 250,000 for globular proteins.

When you use Sephacryl, the difference is clear. Find out more about Sephacryl from your usual supplier of Sephadex®, Sepharose® and other separation media.

Nuclear secrets: no clear frontiers

WHAT is a military secret? And how does it lose its secret status? Until a few years ago, the answers to these questions were thought to be relatively straightforward — a secret was information with the word 'secret' stamped on it; it ceased being a secret when the word 'secret' was removed. But the public, or at least a portion of it, is no longer quite so trusting of military judgement and recently even the holy of holies — details on the construction of nuclear weapons — has been violated in various publications, most notably the article on hydrogen bombs by Howard Morland that has just appeared in *The Progressive*, and the long open leter to US Senator Charles Percy from Charles Hansen, a Californian computer programmer whose pastime is the study of nuclear weapons.

Publication of these documents has been accompanied by some ringing statements about press freedom. For instance, in printing the Hansen letter, the *Chicago Tribune's* Publisher Stanton Cook declared: "We are convinced it contains no secret information that would in any way jeopardise the national security. We are confident that the information was gathered from public records available to any researcher . . . The government's attempt to muzzle a private citizen and the press (is) repugnant to the First Amendment's guarantees of free speech and press . . ."

Now Mr Cook is right (or almost) on two counts. It is indeed possible to accumulate information that is in the public domain and come up with some sound conclusions concerning the design of nuclear weapons. And the revelations of the last month are certainly not going to put the United States at risk — at least in the near future. But to go on to claim freedom of speech and of the press as justification for broadcasting of nuclear weapons data could, just conceivably, be a serious misuse of these fine but not absolute principles.

Consider first the question of the accumulation of public information. There is a serious danger in the view that something is either totally in the public domain or totally secret. There is almost no secret which cannot be deduced if a researcher is prepared to devote enough time, effort and money to the sifting and collating of evidence. The only thing the holder of secrets can do is to make it immensely difficult to extract those secrets. There is thus no great merit in the case that a secret is no longer a secret when it can be deduced from the public domain. It may still be worth keeping the price of learning the secret very high.

But, it may be argued, there is no point in keeping the secret any longer, either because the US government shouldn't be making nuclear weapons (as Mr Morland might argue) or because the US government should go on making weapons, but for other people to know how won't harm the United States (as Mr Cook might argue).

This is to act in ignorance of the Non-Proliferation Treaty. The treaty to which the United States is party, declares that nuclear-weapons states will not in any way assist, encourage or induce any non-nuclear-weapon state to acquire nuclear weapons. It is, of course, debatable whether the two documents in question do 'in any way assist', but simply because there are sincerely held views that they do, there seem powerful reasons why the narrower question of American security should yield to the broader one of global non-proliferation.

None of this should be seen as a blanket endorsement of military secrecy, much of which is preposterous and merely classifies material of low quality to protect it from critical scrutiny by outsiders. Nor should it be seen as in any way a retreat from the view that matters of nuclear policy (as opposed to hardware) are inadequately debated in public, because of the paucity of policy information available, particulary in the United Kingdom. It is simply a statement that in a difficult field where there are no clear frontiers, the case for the recent publications is not as strong as might seem at first sight. □

Overpaid humanitarians

MANY scientists in Britain speak with justifiable resentment about the tax-free salaries that employees of international organisations command. People subjected to no more privation than to live in another country (and sometimes not even to have to learn the language) are frequently paid sums which seem grotesque by continental European and US standards, let alone by those of poverty-stricken Britain.

The latest post to come to our attention is that of Chief of Public Information for an 'International Humanitarian Organisation in Geneva' (which prefers to remain anonymous). The holder of this position will, to be sure, have to be fluent in French and English, and will have to act as spokesman for the organisation running a department of fifteen. The annual salary is round $55,000 to $60,000 — net.

There are highly dedicated information officers in many national humanitarian organisations around the world who count themselves lucky to receive a quarter of this sum — gross. International organisations, particularly those connected with humanitarian aims, have gravely lost their sense of direction when they offer enormous salaries. □

1979 Nobel Prizes for Medicine, Physics, and Chemistry

35th prize for inventor of EMI X-ray scanner

"I'm not the sort of person to build model planes" said Godfrey Hounsfield, co-winner of this year's Nobel prize for medicine, last week. "Ive always searched for original ideas; I am absolutely opposed to doing something someone else has done."

Dr Hounsfield invented the EMI 'brain scanner' for computerised tomography — using X-rays to make two-dimensional images of slices of a patient's brain. "It came to me on a ramble" he said. The device, and its successor, the whole body scanner, brought EMI medical division a ten-fold increase in profits from 1973 to 1977, when the US market collapsed from 40 scanners a month (at £250,000 each) to just eight (see following story).

To date, Dr Hounsfield has received 35 academic awards for his work on the scanner, beginning with the MacRobert Award (the UK's major prize for engineering) in 1972, a Fellowship of the Royal Society, a CBE and many foreign degrees, and ending with the Nobel. He hopes to use his £44,000 prize to buy scientific equipment for his home "so I have something to do when I retire".

Sixty years old and a bachelor, Dr Hounsfield hasn't much time for the arts. "Science has very much a 3rd place in this country; I'd like to do something about that. The sciences are far more exciting than the arts, than fantasy".

Farming educated Hounsfield. "I was brought up in the country; I played around with farm machinery, and to prevent myself being bored I started to reason why things work".

EMI's central research laboratories have provided Hounsfield with "a very relaxed place to do original thinking; and there's just enough pressure to produce a product. It enables one to come to a logical conclusion rather quicker than one would in academic life".

Dr Hounsfield does not know his co-winner, Allan Cormack, and says he first heard of him when he was recommended as a referee for a paper in 1972-3. Cormack had taken a mathematical approach to computerised tomography, whereas, says Hounsfield "I find I've got other tools of thinking than maths — the most important thing is a very broad understanding of the problem, not to be fogged by detail".

"In the last few years I've spent half my time on developments of the scanner, half on other things" says Hounsfield. A new version, the '7000', will cut scan time from 18 to 3s, so reducing the effects of organ movement in the body. "I've always been interested in the heart; we are working on pictures synchronised to the heart to 'arrest' the heartbeat."

Dr Hounsfield has also been working on newer, non-invasive techniques, such as nuclear magnetic resonance. This "looks promising, but isn't diagnostically useful yet. But we've a long way to go before we reach a brick wall." Further developments of the scanner involve a system directly linked to a machine for delivering therapeutic X-rays, so the surgeon can see precisely where he is working. "We're well ahead on that".

Godfrey Hounsfield: started with farm machinery

"The scanner can save money if it's used properly" says Hounsfield. "It's said the head machines can pay for themselves in 2 years" by avoiding the need for exploratory surgery or dangerous techniques like pumping air into the ventricles or heavy metals into the veins of the brain, which are the more traditonal techniques for revealing defects.

Nevertheless the profits of EMI medical electronics have fallen from £14.7m in 1977 to a loss of £12.8m this year, in part because of the spectacular collapse of the US market for the scanner. And meanwhile EMI has been fighting patent rights battles with three US manufacturers of scanners: Ohio Nuclear, which is now to work under an EMI licence, and Pfizer Inc., and GEC.

Robert Walgate

● A six-month tenure at the Groote Schuur hospital in Capetown gave Allan Cormack, a native South African, first-hand knowledge of the limitations of the X-ray techniques being used. "I saw these girls

Dithering on the deadline

PROFESSOR Cormack and Dr Hounsfield became Nobel laureates after a controversy that prolonged the announcement of the prize by more than an hour. Until the last minute, it was unclear whether they or another group would share the award.

The rival nomination was reportedly for a group of three American and French scientists who have made crucial discoveries in immunogenetics. As a result of these discoveries, organ transplant have been made easier.

Exactly who these scientists are is not being revealed. But the Nobel committee, a group of 15 professors from the Karolinska Institute which goes through all the nominations and prepares a short-list, was so sure that the group would be approved that it had prepared its publicity material only on the immunogeneticists, in the usual languages: Swedish, German, French and English.

When the committee presented its proposals to the Nobel Assembly for final decision, however, the Assembly — composed of the 64 full professors at the Karolinska Institute — argued in favour of Cormack and Hounsfield instead. After a prolonged discussion, the committee's secretary, Professor Jan Lindsten, left the deliberations to face the waiting journalists. He made the official announcement in Swedish only: the translations came later. "There was no time to check with the translators" he told *Nature* — and the foreign correspondents had to manage as best they could.

In voting for Cormack and Hounsfield, the Assembly decided to give the prize to applied instead of basic research. The relative merits of these was reportedly one of the subjects of the Assembly's discussion. The information secretary of the Royal Academy of Sciences, Lennart Daleus, wondered afterwards how such a controversy could have arisen at the last minute. By the time the Academy's classes of physicists, chemists and economists present the full Academy with their proposals for the respective prizes, he mused, all the substantive disagreements have usually been ironed out.

Nominations for the medicine prize are invited from many sources. According to Professor Lindsten, invitations to nominate are sent to previous laureates, professors of Scandinavian faculties of medicine, and about 40 faculties of medicine in different parts of the world.

After the drama of the announcement, none of the Assembly's members was willing to talk about the controversy. The remark made by the Assembly's chairman, Professor Georg Klein, was typical of the others' tantalising restraint. "I have a lot of comments", he told *Nature*, "but I can't make them."

Wendy Barnaby

0028-0836/79/420512-02$01.00

preparing all these X-ray treatments, and as a physicist, it struck me as a very rough process," Dr Cormack said. "How can you know how to treat something in the middle of the head if you do not have proper information of the effect on the radiation of the material through which it has to pass?"

The question appealed to him as a scientist. But the task of working out the answer was "mostly a mathematical one", extrapolating what physicists already knew about the attenuation of radiation passing through a homogenous material to similar calculations for inhomogenous materials.

"After publication in 1963 there was virtually no response at all, except for a few physicians, until someone came along in about 1970 to say that similar ideas had been developed by engineers at EMI," says Mr Cormack. He says that he has never met Godfrey Hounsfield, with whom he now shares the Nobel Prize, but adds that "I have heard that the is an inventive person."

Cormack's lack of involvement with the commercial development of computerised comography (CT) scanners means that he has been able to watch from the sidelines the intense debate which has taken place in the US — and which promises to be revived by the Nobel Prize award — over the use of the technology. In particular, this debate has focussed on the extent to which the federal government should support the growth of a technology whose extremely high capital costs have contributed to the rapid increase in hospital care costs in recent years.

Mr Cormack is critical of the US government's decision to place stringent restrictions on the use of CT. This move followed a report from the National Academy of Science's Institute of Medicine pointing out that in many cases, conventional X-ray techniques were much cheaper and might be just as effective (*Nature,* 12 May 1977).

"The arguments against the CT-scanner leave out a lot of things. In doing a cost-benefit analysis, for example, how much to you put in for the pain and suffering of patients for whom exploratory surgery might be avoided by using the scanner?" Mr Cormack says.

"I think the scanner has become a symbol, it is used as a whipping boy as a way of pointing out the expense of medical care; intensive care units probably cost a lot more money, but you do not usually hear about them."

At the same time, however, he admits that the cost of the basic equipment might be brought down if manufacturers were not under great pressure from physicians to improve its performance, for example through faster scans or higher resolution. "A substantial part of the costs must still be in development. If they could standardise the model, the costs would probably go down a lot," Mr Cormack says.

David Dickson

Neutral currents bring rewards

THIS is the prize that many physicists have been waiting for — not least Abdus Salam, of Imperial College, London, and the International Centre for Theoretical Physics, Trieste, and Steven Weinberg of Harvard, whose unified model of the action of the weak and electromagnetic forces has been finding corroboration in an increasing number of experiments.

But one of the severest tests of the theory — the discovery of heavy counterparts to the photon, the 'intermediate vector bosons', is yet to come, and a few will no doubt consider the prize to be premature. Experiments planned at CERN, the European centre for subnuclear physics, for 1982 are expected to provide the first direct evidence of the particles.

However the citation refers to the prediction "*inter alia*" of neutral currents, and here the theory is on firm ground. Sheldon Glashow, of MIT, played a key role in their prediction independently of the machinery of the Salam-Weinberg model, and hence his well deserved share in the prize.

The term 'neutral current' is a somewhat confusing epithet for weak interactions not involving the exchange of electric charge. For example, the familiar weak decay of atomic nuclei involves neutrons changing into protons (or *vice versa*), the excess charge being taken up by the creation of an electron and an antineutrino (or their antiparticles). This is supposed to take place by the emission and reabsorption (exchange) of a *charged* intermediate vector boson between the nucleon and electron systems. Neutral current interactions, on the other hand, involve the exchange of a neutral IVB, and so change protons into protons, electrons into electrons, and so on.

The weak force being extremely weak, the effects of these 'neutral' exchanges are completely masked by the analagous exchange of photons which creates the electromagnetic force between, say, protons and electrons. (It is this analogy, indeed, which allows the two forces to be unified in an all embracing theory.)

The detection of neutral currents has thus proved extremely difficult, and its history has not been without its conflicts of evidence. The first observation was made with neutrinos (where electromagnetic effects are absent) at CERN; others followed, and gradually the neutrino evidence has built up into an impressive body of evidence not only for the existence of the neutral current, but for the exact form of it predicted by Glashow and incorporated by Salam and Weinberg in their (independently generated) 1967 and 1968 unified theory. More recently, a brilliant experiment with polarised electrons at the Stanford Linear Accelerator Center in California measured the interference between the electromagnetic and neutral weak interactions between electrons and protons, and also confirmed predictions.

Robert Walgate

Boron and phosphorus

Herbert C Brown of Purdue University, Indiana, and Georg Wittig of Heidelberg University share the Nobel Prize for chemistry. The citation describes their work on the application of boron and phosphorus compounds respectively to synthetic organic chemistry.

Professor Wittig, who is now over 80 but still academically active, is best known for the development of Wittig reagents, a class of phosphorus-based compounds used to form carbon-carbon double bonds at precisely predetermined places in organic molecules. They have applications in the synthesis of many compounds, including prostaglandins.

Professor Brown, on the other hand, has developed a series of very versatile organoboron compounds which can selectively modify functional groups in organic molecules, and is also renowned for his theoretical contributions to carbo-cation chemistry. His birthplace was in the UK, but he has pursued his career in the US. ☐

Fellowships proposed to help US jobs problem

THE US National Science Foundation should be prepared to spend up to $30 million a year over the next twenty years to reduce the potential impact of demographic changes on the quality of university research, according to a report published last week by the National Research Council, the research arm of the National Academy of Sciences.

Addressing a problem of increasing concern both to research scientists and to science policy makers, the report suggests that the NSF set up a new fellowship scheme to provide support for up to 250 university science faculty members for a period of five years.

In return, the scientist's university would be required to use the money which would have been used to support the scientist to recruit a new faculty member. The report says that the total cost of the programme would be about $381 million (at 1979 prices) over a 20 year period, a sum which would represent about 3% of the NSF's annual budget. After 20 years it predicts that a steady state will have been reached with faculty recruitment balancing retirement and that federal intervention will no longer be necessary.

There are two particular aspects of current demographic changes which threaten — and in some cases are already exerting — a considerable constraint on the ability of US universities to produce high quality research, says the report: declining student enrolment and a low level of faculty retirement in a number of scientific disciplines.

The report points out that whereas in the mid-1960s higher education institutions were expanding at an average rate of 13.2%, the current rate of expansion is only about 3%, and with a rapidly falling number of 18 year olds in the population, "the prospects are very real that such enrolments will actually decline". This has inevitably led to a decline in the rate of faculty growth, it says.

An even greater impact on research, however, is likely to come from the current low retirement rate. This is partly due to the fact that universities expanded rapidly in the 1960s, after a relatively slow build up during the previous decades, and that faculty members recruited at this time are still far from retirement age — and to the impact of new legislation, which will make it illegal after 1 July 1982 for universities and colleges to establish a mandatory retirement age of less than 70.

"It is not known what proportion of faculty who under previous law would have been required to retire at age 65 will instead choose to stay on longer," the report says. It takes some pains to point out that the situation differs between disciplines, the shortage of retirements for example being most severe in fields such as physics and mathematics. "We are concerned that a number of reports in the past have over generalised the problem and are pleased to note that there are some fields, such as the agricultural and earth sciences, where this is not likely to be a problem," Dr Robert M Bock, chairman of the committee which produced the report and dean of the Graduate School at the University of Wisconsin, Madison, told *Nature* last week.

However, the report says that overall, faculty retirement over the next five years will be about 5.5% of the total. A steady state model (which is expected to be reached in the mid 1990s) would imply a retirement rate of 9.2% over this period. "Thus approximately 2900 fewer positions will become available through retirements at PhD granting institutions over the next five years than would in the steady-state with the same total faculty size."

The major effect of these two trends, says the report, will be a reduction in various fields of the number of young faculty research workers. And this is potentially serious for the effectiveness of academic research, not because such research workers have a higher productivity, but because they play a vital role in introducing new ideas and perspectives into the research community.

Furthermore, the report says that "a sharp reduction in the rate of hiring of new PhD faculty might pose a serious threat to the continuation of the progress that has recently been made in expanding the participation of women and minorities in science and engineering faculties." Thus unless ways are found to ensure a continued flow of young scholars into academic positions during the transition to a steady state, "academic research in the United States is likely to suffer serious erosion in the coming decade".

Having argued the case for federal intervention, the report weighs up the arguments for the various forms that this intervention might take. Direct federal support for university faculty positions would, it says, interfere with the normal university process for selecting assistant professors. Similarly effective early retirement and career change programmes can best be implemented and designed at the level of the individual institution.

It also argues against expanded federal postdoctoral fellowship programmes. It states that "post-docs play an enormously valuable role as producers of research, but they cannot be looked to as the principal sources of innovation and renewed vitality in academic departments". Similar reasons are given as arguments against expanding the pool of non-faculty researchers as an adequate response to what is referred to as the "vitality problem".

Setting out the various criteria required for such a response, the report says that these are best met by a programme which provides research awards in support of salary for existing faculty members for a five year period, and requires the university to use the funds thereby released to hire additional faculty.

It therefore proposes that the NSF develop a research excellence award programme, nominees for which must be full-time faculty members on regular appointments. Any nomination made for such an award would have to be accompanied by a staff development plan prepared by the department and endorsed by the university.

"This would be a considerable departure from current NSF practice under which a senior faculty member can win salary support for summer research, and sometimes for a complete academic year, but almost never for a five-year period. Nor is there currently any commitment by the university to use the funds freed in this way to employ new faculty members," says Dr Bock.

No official response has yet been given to the report by the NSF, but it is expected to announce a programme soon.

On top of Mauna Kea: In the foreground is the NASA infrared telescope; on the ridge (left to right) the Canada-France-Hawaii telescope, the 2.2m Hawaii telescope, and the latest arrival, UKIRT

Britain joins Hawaii summit

THE United Kingdom Infrared Telescope (UKIRT) at the summit of Mauna Kea on the island of Hawaii was opened by HRH the Duke of Gloucester on 10 October. Funded by the Science Research Council and operated by the Royal Observatory, Edinburgh, this 3.8-m diameter instrument is the largest telescope in the world designed specifically for infrared observations.

The UKIRT, however, is not the only telescope to have been built recently on Mauna Kea. The NASA 3m Infared Telescope Facility, and the 3.6m Canada-France-Hawaii Telescope have also opened within the past three months, joining three smaller University of Hawaii telescopes already on the summit. In terms of collecting area, Mauna Kea now houses the world's largest observatory for optical and infrared astronomy.

Infrared astronomers will be looking with particular interest at the relative performance of the UKIRT and NASA telescopes, since their design philosophies are significantly different. The British instrument goes for maximum collecting area while in the NASA telescope, which cost about twice as much as the UKIRT, image quality and guiding stability are given the highest priority. The Canada-France-Hawaii telescope and the University of Hawaii 2.2-m telescope are also instrumented for infrared observations.

The UKIRT telescope cost £2.7m and was built by the Sheffield company of Dunford Hadfields, Ltd, using a Cer-Vit primary mirror which was ground and polished by Grubb Parsons, Ltd, of Newcastle. An important feature of the design of the telescope is the thinness of its mirror, which weighs only 40% of that of a conventional telescope of the same aperture. As a result, the whole instrument was built at very substantial saving of weight and cost as compared with, for example, the similar sized Anglo-Australian Telescope. The lightweight structure has the disadvantage of lesser rigidity, but careful design and the use of computer controlled pointing has resulted in an instrument whose performance approaches that of the best optical telescopes.

The instrumentation for the telescope, built in Edinburgh, includes photometers and low resolution spectrometers covering the wavelength range 1 — 40μm. The detectors in use are cryogenically cooled solid state devices such as indium antimonide photovoltaic detectors or gallium-doped germanium bolometers. Stray thermal infrared emission from the sky and from the telescope itself is a major problem in infrared astronomy; the optical system has therefore been designed to minimise the size and effective emissivity of the mechanical and optical components that lie in the telescope beam. In order to separate the signal due to a celestial infrared source from the background emission the secondary mirror itself oscillates at up to 40 Hz, providing the detector with near-simultaneous images of two adjacent areas of sky.

Coast guards probe mystery of missing research ship

WITHIN the next few weeks, the US coast guard hope to have developed a plausible explanation for the mysterious disappearance last December of a research vessel charted by the University of Hawaii with seven scientists on board.

No trace of the vessel, the Holoholo, has been found since it set sail from Honolulu harbour on the afternoon of 9 December. The trip was one of a series planned to gather data on the oceanographic conditions off the Hawaii coast in connection with the siting of a proposed ocean thermal energy conversion (OTEC) project supported by the Department of Energy.

Evidence has been found to indicate that the vessel may have put in to shore to make bench-mark readings for some of the scientific equipment. However, the alarm was raised when it failed to make a planned rendezvous with two scientists two days after its departure from Honolulu, following a period of stormy weather.

On board the Holoholo at the time of its disappearance were three scientists from the University of Hawaii — including the principal investigator for the project, assistant professor of engineering Dr Gary C Niemeyer — two scientists from the University of California's Lawrence Livermore Laboratory, which has responsibility for the OTEC research programme, and two scientists from the National Oceanographic and Atmospheric Agency.

Various theories about the disappearance have been voiced during extensive hearings that have already been held in Honolulu by a board of enquiry established jointly by the coast guard and the National Transportation Safety Board. These range form the hypothesis of an explosion on board to the suggestion by some, quoting the Glomar Explorer's links with the CIA, that the vessel might have been captured by a foreign power.

According to a local newspaper, the Honolulu advertiser, the board that the boat sank after being swamped by heavy seas — and that the swamping may have been partly due to structural alterations made to the vessel to accommodate various species of equipment required for the research.

The safety board has already issued a set of recommendations to the University following the Holoholo's disappearance in which it says that some of the alterations, which included the installation of two large winches, a large spool of cable, and an A-frame cargo boom on the after part of the vessel, "may have adversely affected the

0028-0836/79/420515-02$01.00

seaworthiness of the vessel".

The board points out, for example, that although the chief scientist principal scientist was "a highly regarded investigator with considerable knowledge and experience in ocean research", there was no evidence that he or the other scientists had expertise in vessel seaworthiness, stability, or navigation.

The board also raises questions with regard to the adequacy of procedures adopted by the university for observing guideline safety standards for research vessels laid down in may 1976 by the University National Oceanographic Laboratory System (UNOLS), based at Woods Hole in Massachusetts, an Association of Oceanographic Institutions.

It points out that although these include "an excellent array of standards and procedures which would be applicable to most research vessel operations", and despite the fact the University of Hawaii is member of UNOLS, the guideline standards had not been applied to the Holoholo, which was not owned by the university but had been commissioned through a subcontract with the university's research corporation.

As a result, says the board, the operation of the Holoholo apparently relied on the charter contractor for vessel seaworthiness, on the contract with the boat's master — of whom there is no evidence or expertise in vessel stability — for safe operation, and on the judgement of the chief scientist as to the suitability of the vessel to serve as a platform for the research projects to be conducted.

"There is no evidence that any of the guidelines standards were considered or applied by three individuals involved or by any other officials of the university or research corporation" the board says.

Officials at the university, which may be sued for substantial damages by the relatives of those on board the vessel when it disappeared, have declined so far to make any public statement about the incident, apart from saying that the specific recommendations of the safety board to prevent similar occurences in the future" are now under study by university officials. **David Dickson**

Drought could turn Dead Sea into a desert

Dead Sea: getting deader

CROSSING the Dead Sea on foot is now theoretically possible — if it weren't for the presence of border patrols — according to Shlomo Drori, a leading Israeli expert on the use of Dead Sea resources. Following the worst drought in the history of the State of Israel, the sea has split in two at its narrowest point.

The Dead Sea's sole feeder is the lower Jordan, which is becoming increasingly depleted by water developments, both Israeli and Jordanian. Last November, even before the onset of the drought, Yigal Allon, the former Israeli foreign minister spoke in the Knesset of the "urgent" problem of the Dead Sea. Current Jordanian water projects involve the damming of all eastern tributaries of the Jordan; when these are completed, said Mr Allon, the lower Jordan would totally disappear save as a drainage channel, the Dead Sea level would fall signifacantly, and the southern part of it would become a salt desert. This, as the Energy Minister Yitzak Moda'i admitted in his reply to Mr Allon, could cause "tremendous" and possibly irreversible ecological damage.

It is, however, Israel's water schemes which are the main consumers of sources which would, without human intervention, end up in the Dead Sea. For the lower Jordan flows from the sea of Galilee, which, via the National Aquifer, serves as the water source of the whole country. According to Professor Yoram Avnimelech, a soil chemist seconded from the Technion to the Sea of Galilee Conservancy Board, considerable problems are posed to conservationists by the unique status of the Sea of Galilee, including its religious and historical associations. The normal way of treating a lake scheduled as a drinking water source, he told *Nature,* is to fence it off, minimise development of the watershed, and try to keep the population out. This, however, is not possible in Israel, which has a limited supply of water — indeed, in the summer, every drop of water from the springs of the Upper Galilee is used three times by irrigation and fish-farming schemes before it even reaches the Sea of Galilee.

On occasion, the needs of the Conservancy seem to run counter to Israeli national sentiment. In 1968, workers at the Limnological Laboratory at Tevhag began to observe excessive levels of nitrates in the water, due not only to the use of fertilisers in the Upper Galilee but also to the uncovering of the organic soils of the Huleh valley. Since the reclamation of the Huleh marshes has attained a saga-like status in Israeli history, the obvious alternative of reflooding the Huleh was simply not acceptable, but it took several years of intensive research before a suitable strategy was devised to obviate the danger of eutrophication posed by the excess nitrates. (This is based, incidentally, on short-term sprinkling of the Huleh soil at high summer temperatures to encourage the action of denitrifying bacteria).

Professor Avnimelech, who is very much the scientific trouble-shooter for the Sea of Galilee Conservancy, also indicated another area where Jewish sentiments and the needs of conservation may yet clash. "Planting a tree in Israel" is a tradition with considerable emotional overtones to Israeli and Diaspora Jews alike — yet recent indications, Professor Avnimelech said, suggest that over-zealous tree-planting in the Galilee watershed may be causing environmental deterioration.

Yet, however well the Water Conservancy Board husbands the Galilee resources in times of drought, the Sea of Galilee itself may be at risk. This summer, the water level fell dangerously low, and when the rain finally fell just before Jewish New Year, one official revealed that no water had been taken from the Sea of Galilee for almost four months — the country had been subsisting solely from supplies stored in auxiliary reservoirs along the aquifer.

As far as the depleted — and now divided — Dead Sea is concerned, there does exist one fairly obvious means of replacing the waters lost to human needs. This is the construction of a canal to bring in water from the Mediterranean. Israel, of course, does not have the funds to contemplate such a scheme merely as an ecological rescue operation. However, the Dead Sea lies some 400 m below the level of the Mediterranean, so that, the canal could descend via series of hydroelectrical cascades which could according to current calculations, produce up to 10% of Israel's

0028-0836/79/420516-02$01.00

present generating capacity. Although, according to Energy Minister Moda'i, electricity can still be generated more cheaply using fossil-fuelled power stations, granted the need for such a canal, power-production might make it economic.

One early exponent of such a canal was American pioneer of land conservation, William Clay Lowdermilk. In 1939, Lowdermilk formulated an "eleventh commandment" for the future state of Israel. This reads, in part: "Thou shalt safeguard thy fields from soil erosion, thy living waters from drying up . . . .". This summer's drought has made it imperative that this "commandment" should be extended to include not only the "living" waters of the Jordan and Sea of Galilee but also those of the Dead Sea.

Vera Rich

UK plans nuclear expansion

BRITAIN'S Conservative government is expected to announce details of a £10bn nuclear expansion programme within the next few weeks. The plan will involve building up to 20 nuclear reactors to supply half Britain's electricity needs by the year 2000. The Conservative cabinet is unanimous in its support for nuclear power, the only disagreements being over reactor type.

At present it is believed the American pressurised water reactor of the type involved in the Harrisburg accident is the leading candidate because it can be brought on line in five years, half the time needed by the advanced gas cooled reactor. Two public inquiries will be held before the plan can be enacted. One is a planning inquiry about the siting of the PWR, the other a full public inquiry about the necessity for a fast breeder reactor for Britain's nuclear future. Although strong opposition plan to counter it. "They will wait and see how effective the opposition is before taking counter measures" a Department of Energy spokesperson told *Nature*.

USSR questions nuclear safety: For the first time, the Communist Party has published an article on negative environmental effects of nuclear power. The article, in *Kommunist*, the party's theoretical journal, was co-authored by Nikolai Dolezhal, a prominent nuclear scientist, and Yurii Kroyakim, a relatively unknown economist. It questions the amount of valuable agricultural land that would be used, the effect on water supplies and the difficulties of storing nuclear wastes.

The article stresses that the sheer scale of the programme involving an expansion from the present level of 10 million kW to over 110 million kW by 1990 plus the construction of nuclear power stations in western Soviet cities as sources if district power heating would encroach considerably on agricultural land. Previous Soviet comment has characterised the anti-nuclear movement as being inspired by oil companies anxious to preserve their market position.

French demo blocks fuel: In a militant demonstration against nuclear fuel reprocessing, French trade unionists and environmentalists held up the unloading of 15 tons of spent nuclear fuel from Japan. Nearly 2,000 demonstrators met the ship chartered by British Nuclear Fuels Ltd when it docked at Cherbourg on 9 October with its cargo for reprocessing at nearby La Hague.

Demonstrators blocked a railway siding, severed an electric cable and put a crane out of action in a successful attempt to block the unloading. The Socialist Party and the socialist trade union federation the CFDT are demanding a national debate to prevent France from becoming "the nuclear dustbin of the world".

Waste disposal plan could take a decade: An independent waste disposal plan produced by the state of California has caught the nuclear industry by suprise. The plan calls for simulated waste to be placed in experimental vaults 1000 metre under ground in variety of geological formations. Measurements would be taken on migration rates as a function of rock type, temperature, depth, and pressure and the findings compared to theoretical predictions.

The entire process would take ten years and is recognised to be the only valid way to assess present underground storage plans. The federal government accused the state government of ignoring national energy policy and of failing to keep Washigton informed. The move is widely regarded as a show of strength by the anti-nuclear movement and is expected to give a boost to California governor Jerry Brown's campaign for the presidency.

Protestors march in Bonn: In the largest demonstration since the early 1930s, protestors demanded an immediate end to the development of nuclear power is West Germany. Individual columns stretched more than 2½ miles as 100,000 activists including representatives from the US Austrian, Danish, Dutch, French and Swedish anti-nuclear movements converged on Hofgarten park in central Bonn last Sunday. Demonstrators gave a standing ovation to a speech from Kathy McCaughin of the Harrisburg Citizens Action Group who called for a stop to "the nuclear madness now". Trade union speakers were applauded when they said that more jobs would be created by alternative technology instead of nuclear power.

Syrians blast UNCSTD over power politics

SYRIA'S delegation to UNCSTD returned home unsatisfied and a little angry. "We know that the problems of development cannot be solved with one conference, but at least we could have made a start", says Dr A W Chahid, Director of the Centre for Scientific Studies and Research in Damascus and a leading member of the Syrian delegation.

The future for the developing countries after UNCSTD, says Dr Chahid, is "just as hazy as it was before. We came back from Vienna even more convinced of the inherent biases and injustices of the existing scientific and technological order in the world".

Most of the developing countries were not prepared for the tight, hard-nosed negotiations and power play that was conducted by the developed countries at UNCSTD. Dr Chahid is particularly critical of the petty politics and the infighting of the European Community countries. "The attitude of the Nine to the proposed Development Fund was quite pathetic", he says. (A fund of $2 billion to 1985 proposed by the Group of 77 was cut to $250 million to 1981.) The Nine were also responsible for frustrating the good intentions of "the Nordic Group which was quite forthcoming and ready to make a reasonable contribution to the fund".

Dr Chahid thinks it was unfortunate that the Group of 77 was dominated by countries that are at the top of the development continuum. India, Brazil, Yugoslavia and other members of the 'Group of 27' of the Group of 77 who took part in the negotiations have a reasonably developed scientific and technological infra-structure. "It is these countries which stand to gain most out of the few achievements of UNCSTD".

But what about the really poor countries that suffer from the "small country problems", that do not have even the tiniest form of science and technology infrastructure? "What do they get out of UNCSTD?" asks Dr Chahid. "We must ensure that they get the lion's share of the Development Fund, little though it is".

The power and coordinating ability of the Group of 77 will be tested to the full in the setting up of the UN intergovernmental committee that will administer the Development Fund. Dr Chahid argues that if all members of the Group of 77 took an active interest in the intergovernmental committee and if there was "a very strong Group of 77 representation on the Committee", it may be possible to steer development in the Third World's favour.

However, Dr Chahid points out that many developing countries, including Syria, do not have a representative in New York.

news in brief

Western nations increase proportion of R & D funds spent on military research: The proportion of research and development funds spent by the United States and Western Europe for military purposes increased from 38.5% to 39.2% between 1975 and 1977, according to a report published last week by the US Arms Control Association and the Institute for World Order. The amount of money spent on military research increased from $12.8 billion to $15.4 billion, says the report, which points out that the global expenditure on military purposes exceeded the rate of inflation for the seventh year, reaching a total of $425 billion.

The report says that the R & D component of military spending is significant not only for what it has produced, but also for the continuing momentum that it gives to the arms race generally. "The steady improvement in technology has made the pace of national military spending essentially independent of the existing threat to the nation."

"In the superpower competition, each side considers it essential to develop and produce whatever is technologically possible, on the grounds that the adversary may do so. R & D is the instrument through which 'antagonistic cooperation' between the two leading adversary nations ensures a never-ending escalation of arming."

World Military and Social Expenditures 1979, by Ruth Leger Sivard. Single copies $3,50. Available from Work Priorities, Box 1003, Leesburg Va. 22075, US.

Czechoslovakia considers ecology of uranium mining: Czechoslovakia's Minister of Energy Vlastimil Ehrenberger announced last week that the country's uranium industry had met all its increased production targets. Attention was also being given to the ecological aspects of uranium mining. In a 40-minute speech on the state of the energy industry, he told the Chamber of the People that new uranium ore deposits now ensured a "reliable base" for the country's nuclear energy industry. A large ore-processing plant, built with Soviet assistance was operating in North Bohemia. Exports of uranium to the Soviet Union were well up to target, and a scheme is being worked out for the future of the uranium industry after 1980, when the agreement signed in 1945 for supplies to the Soviet Union, runs out.

Rattled: Pennsylvania rattlesnake steaks are no longer on the menu at Dominique's restaurant in Washington DC. The rattlesnakes have been spared as the result of a letter to the restaurant's owner by C.K. Dodd, an endangered species herpetologist at the US Department of the Interior. But Mr Dodd's intercession on behalf of the Pennsylvania rattlesnakes may have cost him his job. US Secretary of the Interior, Cecil D. Andrus, a patron of the restaurant, apologised to the owner Dominique D'Ermo, for his employee's action assuring D'Ermo that the snake "is not listed as either threatened or endangered under the Endangered Species Act'; and Mr Dodd received a four page latter of dismissal.

The most serious charge against Mr Dodd seems to be that the wrote his letter on Department of the Interior Stationery. He admitted that he might have been at fault, but claimed "Even if it is against the rules most people would get a simple slap on the wrist or a reprimand". He plans to appeal. *Anne Norman*

Vietnamese claimed to use poison gas: US representative Jim Leach released a report last week which claims that a number of Hmong refugees had witnessed or had been victims of seven poison gas attacks in the past year. The Hmong are a hill tribe in a remote area of Laos. They were an ally of the French and then the Americans during the wars in Indochina. According to the report, refugees from the tribe described poison gas attacks in which gas was dropped from planes in bombs or sacks which exploded 200 to 300 metres above the ground. Dozens of villagers were killed or have become ill as a result of them. The Vietnamese Embassy in London told *Nature* that the report was untrue and was an attempt to discredit the Vietnamese government "Only the US has used poison gas against the people of Indochina."

FOE takes action against "Tories cold war": Friends of the Earth in UK are launching a major campaign to force the UK government to supply adequate heating for its citizens this winter. Calling Britain's insulation standards a "national disgrace", FOE is critical of the lack of government incentives to provide insulation for houses and of the failure of the government to live up to its election promises. "It is ironic that in International Energy Conservation Month, the government is actually cutting its energy conservation programme while at the same time it is embarking on a potentially disastous major expansion of nuclear power." On 18 October a FOE team will instal insulation in a London home to make it "the best insulated flat in Britain" as a demonstration project to kick off the campaign.

"Don't worry, market forces will keep you warm!"

US firm cited for causing fertility hazards: The US Department of Labour's Occupational Safety and Health Administration last week cited the American Cyanamid Company for violating health standards by threatening the child-bearing capacity of female workers at a chemical factory in West Virginia. Last year the company admitted that it had refused to let women work in the plant's lead pigment section unless they had been sterilised, since it was concerned that the work might result in harming feotuses or affecting the women's fertility. The company says that it offered the women other jobs, although possibly at lower pay; however four women at the plant disclosed that they had been voluntarily sterilised in order to keep their jobs.

Announcing that a fine of $10,000 was to be levied on the company for violating health and safety standards by creating such working conditions, Dr Eula Bingham, head of OSHA, said that the agency was "breaking new ground" in its actions. "What this citation is saying is that companies are required to make the workplace safe for men and women. Part of making it safe is making it safe for reproductive capacity," Dr Bingham said.

The citation requires American Cyanamid to stop insisting that female workers working with highly toxic lead be sterilised.

Socialist countries discuss joint research: Representatives of the Academies of Science of the Comecon bloc met in Tallin (Estonian SSR) last month to discuss the main directions for joint research for 1981-85. According to the protocol of the meeting, joint research is to be extended in the fields of petrochemistry, quantum chemistry, mechanics, machine-design and technological processes. A longer-term draft cooperation programme in the natural sciences up to 1990 was also discussed. The meeting formally welcomed the Socialist Republic of Vietnam (represented by its National Centre of Scientific Research and Committee of Social Sciences) into the multilateral scientific cooperation agreement of the Academies of Sciences of Socialist Countries of 15 December, 1971.

Holland's science shops for 'made-to-measure' research

Tony Ades reports on unorthodox efforts by radical Dutch scientists to match their work to the needs of society

SCIENCE shops in the Netherlands continue their steady growth and development. The annual report, to be released at the end of October, from the country's most established science shop at the University of Amsterdam, reflects an increasing scale of operations and plans for a deeper integration within the university structure.

Science shops (Wetenschapswinkels) are part of a movement that started in the early 1970s to provide a counterweight to government and industrial domination of science policy. Groups of radical scientists and students were then already organising themselves to distribute expertise and technical assistance to trade unions and other groups to whom it was not otherwise available. Mr F H P Trip, the Minister for Science Policy under the former liberal Labour government, had suggested that efforts of this sort should be supported as part of a broad attempt to democratise science.

A science shop does not undertake research itself. Its role is simply to put its clients, any group with a question, in touch with university staff able to do the research needed to answer it. The research itself is done on an unpaid and voluntary basis: faculty members must integrate it into their existing programmes, or students may undertake it as part of their dissertation. Science shops are therefore very cheap to run. Their costs need only cover advertising, copying, office expenses, and salaries for a small staff. The attraction is that the university can experiment with a novel relationship between the scientist and society, with minimal risk to the quality of education, and at negligible expense.

The movement gained impetus in early 1977 when the University of Amesterdam decided to reserve Dfl. 30,000 (£7,500) to start a science shop. The Secretary of State for Education in the present Conservative government cancelled this allocation, but the widespread protest that followed encouraged the university to take protective action: it established its science shop as an advisory committee to its governing board, a position where it remains virtually immune to political interference. The shop was duly opened in March last year, by the former minister Trip, and now has a budget of Dfl. 70,000, and a staff of four.

This year it fielded 550 enquiries, an increase of 50% on last year. Most came from unions (30%), environmentalist groups (20%) and neighbourhood organisations (15%); but a very broad range of clients was represented, including womens groups, welfare workers and individuals. 180 of these questions have been answered in the form of full research reports or written or oral advice. A further 100 were withdrawn or unsuitable, and the remaining projects are still under way.

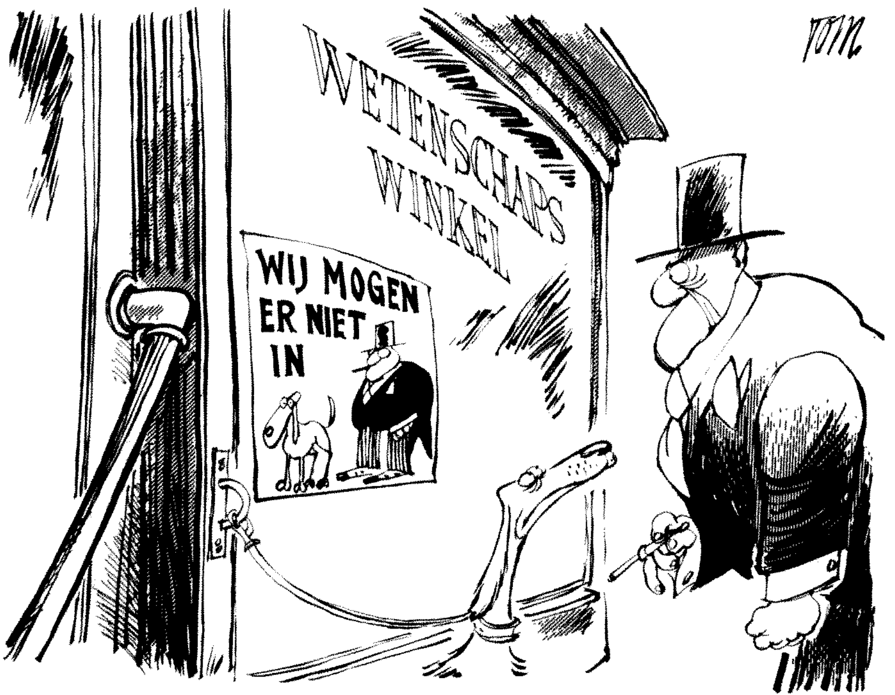
While it is the strongest, Amsterdam's shop was by no means the first. Science shops also operate from universities and technical colleges at Delft, Eindhoven, Groningen, Leiden, Maastricht, Nijmegen, Rotterdam, Tilburg, Utrecht and Wageningen. There is considerable variation in both the mode of affiliation to the parent university, and in the level of financial support. But support is increasing, and new shops are still being opened.

The most controversial aspect of the science shop movement is the criteria by which clients are selected. Any group or person may approach a shop, as long as they are unable to do the research themselves (or have it done elsewhere), have no financial interests in the results, and are in a position to use the results in a positive way. Because these criteria are explicitly intended to select for minority groups and exclude commercial interests, they have attracted the disapproval of the Minister of Education, Mr Arie Pais. In an open exchange with the University of Amsterdam in April this year, he agreed with the democratising role of science shops, but charged that the criteria threatened the "objective and unprejudiced" position of universities in society. Dr Loet Leydesdorff, chairman of the Amsterdam shop, answered that science shops were in fact furthering the university's public function by re-evaluating society's need for science, and orienting research to public ends. He added that there was nothing objective or unprejudiced about the government decisions that brought so many clients to the science shop door.

The matter is expected to remain at this impasse for some time. Science shops receive warm support from unions, students and the press; and while there is certainly ambivalence within some universities, the concept is so widely regarded as rational that strong opposition is seldom voiced in public.

The research questions that clients bring in are extraordinarily diverse, both in scale and in substance. Public and industrial health are perhaps foremost, and a number of universities have set up specialised chemistry shops to analyse potentially hazardous industrial by-products and check pollutant levels. Eindhoven's physics shop has dealt with a number of clients worried about traffic noise. In one project a speed meter was built so that a neighbourhood group could obtain accurate information on how fast cars were travelling down a particular street. In such cases, which are quite common, the science shop can be very effective in redressing imbalances in the availability of science. A local authority may drag its heals over vague protests about traffic or pollution, but it will give a serious hearing to citizens groups with hard data. Without science shops such data would often remain inaccessible.

In different universities there are shops specialising in architecture, agriculture and biology. In the latter field there are numerous enquiries into the effects on



"You can't come in here": money-making industrialists are banned from science shops

0028-0836/79/420519-02$01.00

animals and plants of waste dumping and weed killers, and on the environmental consequences of various farming practices.

Although science shops were originally oriented towards the exact sciences, and gained much of their early support in the health and pollution field, many of the questions now command attention from sociologists, economists and phychologists. In one recent incident, suspicions were aroused by a questionnaire that the Hilton Hotel planned to circulate among its staff. The union took advice from a sociologist and decided to boycott the questionnaire and design their own. There are numerous requests for research into the physical and mental health effects of projected highways, factory and housing developements. Second only to public health issues at Amsterdam are calls from labour unions who need to know about the likely effects of changes in management policy on conditons and employment levels in specific factories. Sometimes, prognoses on a company's balances are required.

Occasionally a science shop is called upon to provided a summary and inventory of research to date. Such requests have been received, for example, from a women's group concerned about 'the pill' and its side-effects. Often the client is simply directed to relevant literature, and the shop arranges for the material to be made available through the university library.

Some clients would exhaust the services of several think-tanks: on the books at Nijmegen are number of questions concerning energy. These include a comparative study of different energy sources, the general health risks of nuclear energy, calls for research into reactor design, how radiation norms are set, and the worldwide proliferation of nuclear facilities. Such issues should clearly be handled on a nationwide level: representatives of the different science shops meet once or twice a year, but their different internal structures and connections with their parent universities tend to inhibit coordination.

At the more light-hearted end of the scale was a question from a neighbourhood group: "Why do people like dogs? What are the psychological effects on the dog of living in a flat?" Another group, living near a milk factory, asked: "Is milk powder damaging to car-paint?" More ethereal but equally practical is the project suggested by a question put in by a political action group: "How can political action groups be most effective?"

While there is at present a mood of optimism and growth, the long term future of science shops is unclear. In Dutch universities research funds are distributed to sub-departments whose faculty plan their research programmes, with varying degrees of democracy, as a group. The group may earmark as much money as it wishes for socially-oriented research. Science shops will therefore survive as long as liberal scientists dominate the faculty groups. Indeed, at Amsterdam there are plans to close the gap between scientists and the public still further. Project centres are to be set up, each one responsible for a cluster of questions. As experience with clients' needs develops, the project centres will be able to formulate research priorities and feed socially oriented science policy back to the faculty groups.

But at some universities support for the science shop concept is much more tenuous. The shops depend on a small core of enthusiastic students and staff, operating in what they regard as a hostile environment. Many of the more radical proponents of science shops feel that this lack of institutionalisation is their best guarantee of a free hand, and are suspicious that the "professionalism" at Amsterdam is a capitulation. This is probably more a reflection of the different attitudes of the parent universities, than a real ideological split in the movement. The stress on working with rather than for the client, and the criteria by which clients are selected are strikingly consistent from one shop to another.

Yet there remain far more projects on the books than scientists willing to undertake them. It is widely agreed that the bottleneck arises from the clash between the career structure of the scientist and the interdisciplinary nature of the projects that clients bring in. The desire to do socially oriented research is quite strong: but so is the desire to have dissertations approved and papers published. the university scientist is under pressure to break new ground and to restrict research to the more tractable issues. Only the daring will tackle the open-ended questions asked on the other side of the science shop counter.□

Dutch minister warns of research cuts

Industry in the Netherlands is slowly cutting the money it spends on research and development, and concentrating on existing work rather than new developments. This warning was given by the new minister for science policy, Dr A. van Trier (above), in announcing his science budget for 1980. The 6.1 billion guilder budget is 417 million guilders up on this year's figure, but the bulk of the increase will be borne by the government. Industry's spending will go up by only 2.5% instead of the expected 9%.

The budget makes special allowance for industrial and technological research. Energy research will give a new importance to coal, which has been largely neglected since the introduction of natural gas led to the closure of Holland's mines in the 1960s. Now, plans to import foreign coal have brought it back into favour.

Dr van Trier proposed a new "minimum" programme for nuclear research, confining it to acquiring the technology necessary for the possible building of power plants and concentrating on safety, waste disposal and general health and environmental aspects. Only when an acceptable solution has been found for the problems of waste disposal, the safety of power plants and the risk of sabotage and terrorist action will three more nuclear power plants be built, Dr van Trier said. A decision in principle to go ahead with these was taken in 1974 but since then the argument about nuclear energy has intensified and the government now plans a broad and structured public debate, beginning next year. A decision about new power plants is not expected for two years. Research on fast breeders is to be reduced.

The science budget coincided with publication of a long-awaited energy memorandum which sets out the government's policy for the forthcoming debate. Conservation and diversification of resources are the two main features. Use of energy is expected to increase by between 52% and 86% by the year 2000 but the aim is to improve efficiency by 30% over the same period. Investment of up to 63 billion guilders will be necessary to reach this conservation goal, the memorandum says, to subsidise more and better insulation in houses and buildings and more efficient heating systems.

Alternatives like solar energy and wind power are expected to play only a minor part by the year 2000. The contribution of natural gas (now half of total use) is also likely to drop to 30% or less and will cost the consumer more. The government plans to be especially economical with the huge Groningen gasfield and switch slowly to other gas sources in the North Sea, Algeria and possibly Nigeria. The use of natural gas for electricity production will be phased out and replaced by oil and coal.

Casper Schuuring

Séveso: the crucial question of reactor safety

A technical report on what caused Italy's dioxin disaster has too many loopholes, writes **Alastair Hay**

ITALIAN chemists and engineers investigating the causes of the trichlorophenol reactor accident in which the toxic chemical 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin (dioxin) was discharged over the town of Séveso on 10 July 1976 have recently completed their report. Results of the investigation, carried out on behalf of the Italian Judiciary, form the first of several reports being prepared for the prosecution case against ICMESA, Givaudan and Roche, the owners of the trichlorophenol reactor. Other reports expected soon will cover the medical, agricultural, environmental and veterinary consequences of the accident.

The dioxin discharged contaminated a large area forcing over 700 people to be evacuated from their homes. Over 100 children in the area developed mild to severe forms of the disfiguring skin disease chloracne following contact with dioxin. And over 100 Séveso women are reputed to have had abortions — either in Italy or in other European countries — fearing the teratogenic properties of the contaminant; official Italian figures only refer to 34.

Many of the medical consequences of the Séveso accident are not subject to dispute. The long term effects, however, are still a matter of controversy owing to the recently confirmed carcinogenic properties of dioxin. But the subject which still generates real heat is the design and operation of the Séveso reactor. The latest Italian report will add more fuel to the controversy. But sadly, the report has some serious faults, chiefly because it makes claims without supporting evidence and accusations which are not borne out by further investigation. If used as the basis of the prosecution case against the reactor proprietors in its present form, much of it will not stand up to a rigid cross-examination.

The process to make 2, 4, 5-trichlorophenol involves the alkaline hydrolysis of tetrachlorobenzene with sodium hydroxide at a temperature of 170 — 180°C, in the presence of ethylene glycol as a solvent. In the course of the reaction, and particularly at elevated temperatures, two molecules of 2, 4, 5-sodium tricholorophenate condense to form 2, 3, 7, 8-tetrachlorodibenzo-p-dioxin.

Dioxing formation is unavoidable during this process, but the quantity produced can be controlled by keeping down the temperature. Should the temperature rise and reach 230°C an exothermic reaction involving some of the reactor contents is initiated, heat is generated, the temperature rises rapidly and a considerable quantity of dioxin is formed. In a closed reaction vessel such as that used for trichlorophenol manufacture, the rising temperature leads to an increase in pressure and the eventual rupture of the reactor. At Séveso, the pressure blew the safety valve, venting the reactor contents over the residential area nearby.

It is the view of the report that the reactor was unsafe and the three companies involved are charged accordingly. The companies are: ICMESA — owners of the trichlorophenol reactor; Givaudan, ICMESA's parent company; and F. Hoffmann La Roche, of which Givaudan is a subsidiary. The report's clear intention is for all three to share the blame for what happened at Séveso, and the trio have never questioned this.

Also unlikely to be challenged is the report's statement that the condition of the reactor when it was closed down at the end of the run on 10 July 1976 was unusual and that it was the first time it had been left in that condition. Givaudan say this is true. But when confronted with this in court, the company is expected to argue that the reactor should never have been left as it was, but that water should have been added to the reactor after the run to cool the contents. The company also considers that it should have been informed by its subsidiary ICMESA, of any changes in operating procedure before they were introduced.

Solvent ratios — a dangerous deviation?

One of the more serious charges which Givaudan claims it can dismiss concerns the operating conditions of the reactor. The report says that the ratio between the solvent ethylene glycol and the starting product tetrachlorobenzene was too low, and this, it insists, was a "deviation from the process originally developed in [Givaudan's] patent USP 2,509,245, where the critical nature of this ratio was expressly mentioned". In the report's judgement the alteration in this ratio increased the risk of accident.

Givaudan admits that the molar ratio of the two solvents used at Séveso was 5.6 whereas the initial patent recommended a ratio of 8. However, the patent taken out in 1950 makes clear that this ratio was important only for the yield and quality of the trichlorophenol product.

The company's claim is surported by a recent review in the Italian journal *La Chimica el'Industria,* **61,** 108 (1979). Dr Giuseppe Ferraiolo of the University of Genova refers to the critical nature of the ratio between these two compounds. Mentioning various patents for the production of trichlorophenol Ferraiolo shows that only if the ratio is less than 5 is there a danger of an uncontrolled exothermic reaction occurring. Even at a ratio of 5 the reaction remains stable up to a temperature of 240°C.

Givaudan have confirmed they will contest one of the report's suggestions — concerning the relationship between the temperature reached by the Séveso reactor and the quantity of dioxin produced. In the conclusions of their report, the Italian chemists say that it is impossible to calculate the quantity of dioxin produced in the incident from the temperature of the reactor contents, and the concentration of dioxin in the residue left after the accident. No experimental evidence is advanced in the report to support this claim. Givaudan, on the other hand, claim that they have their own to refute it.

For the past three years the company has carried out numerous experiments in an attempt to recreate the conditions which precipitated the Séveso accident. So far this research has been unfruitful and the company is still unable to explain what happened at Séveso. However, what Givaudan does claim is that on the basis of its experiment it can predict how much dioxin is produced simply by knowing the temperature of the reactor contents. The company spokesman claimed that dioxin concentration increases with increasing temperature. This he says has already been reported (see *Nature* **273,** 582; 1978). From their evidence Givaudan claim that 530 g of dioxin was produced of which 240 g was ejected from the reactor. Givaudan calculated that the dioxin content of the reactor was 115 ppm; the Italian report says the measure value is 100 ppm.

Givaudan's experiments are to continue; some results, such as those concerning the nature and properties of the chlorinated phenols produced in trichlorophenol reactors, are expected to be published shortly. Asked to put a time limit on the experimental work Givaudan's spokesman was unable to do so. In the company's eyes, he admitted, this research might be considered "unproductive work". He still regretted, however, the fact that the company had not come up with any answers yet to explain the Séveso accident.

Much of the evidence in the medical and other spheres which will be presented in court aginst the reactor owners will be irrefutable. This, however, is unlikely to be the case where the operation and design of the reactor is concerned. Perusal of this first report of the Italian investigators suggests that they have not done enough homework, and that their prosecution case will be anything but convincing.

It is regrettable that the chemists have not focused more attention on inadequate safety devices for example the lack of a dump tank to contain any overspill from the reactor. The chemists would have been on surer ground here, for in spite of Givaudan's claims that the Séveso accident was 'unforeseen' it happened, and the consequences were appalling. ☐

Fast reactors do produce 60 times more energy than thermal reactors

SIR,—Despite Dr Jeffery's reference to "nuclear nonsense" (13 September, page 98), fast reactors do produce about 60 times more energy from the same quantity of uranium than do thermal reactors. The full reduction in uranium demand brought about by the introduction of fast reactors into a power system will not be achieved until all the thermal reactors have been replaced by fast reactors. The rate of replacement depends on many factors, including the particular rate of growth of the electricity demand, the breeding gain of the fast reactor, and the amount of plutonium needed for the initial charge of each reactor. For the particular parameters used in the calculations quoted by Dr Jeffery, uranium ore demand up to the year 2020 was reduced by a factor of 1.7, but he did not point out that some 10-15 years later there would be no need for any further uranium imports: a situation which would continue for centuries.

Dr Jeffery quotes calculations by Grainger and Merrick based on a 5.5% exponential growth rate. Such a high growth rate could not be sustained over a long period: it is about double the average growth rate over the last decade and would result by 2020 in a near 10-fold increase of the present installed generating capacity and a fuel consumption of 10^9 tonnes coal equivalent per year.

If a growth rate of much above 3% were to be maintained for one or two decades, two factors would become important. Firstly, reactor designs (which already exist) with better breeding performance than those currently specified, would be favoured. (Even the current designs have a better breeding performance than that assumed by Grainger and Merrick.) Secondly, the rate of introduction of fast reactors could be increased by fuelling some of the new reactors with U^{235} instead of plutonium. Even for a growth rate as high as 5.5% it would then still be possible to reduce uranium imports to zero within a few decades.

Yours faithfully,

The National Computing Centre is not a quango

SIR,—I support the point made in your leader 'Hunting the Quangos' (2 August); Quasi Autonomous non-Governmental Organisations have undertaken many essential tasks in the public interest more effectively and for less cost than would have been the case if government departments had been used.

However, the inclusion of the National Computing Centre in your list of Quangos is incorrect. We could debate whether, or not, it ever was a Quango, depending on one's choice of definitions, but there is no doubt that today there is nothing 'Quasi' about the NCC's autonomous state.

In March 1978 an Extraordinary General Meeting changed the status of NCC from a grant-aided body to full independence. Monies received from government sources (about a quarter of the budgeted revenue of £4.4 million) are in payment for contracts or projects undertaken on behalf of government departments. A definition of Quangos on this basis would include many independent commercial or industrial organisations which undertake government contracts.

The only formal link with government in the present NCC constitution is the Secretary of State for Industry's power to recommend two directors (out of 19) and approve changes to the constitution. In no way does this influence the independence of NCC in its day to day activities, which, incidentally, include export earnings of nearly £300,000.

Yours faithfully,

D FIRNBERG

The National Computing Centre, Manchester, UK

Farm or laboratory for male chicks?

SIR,—Lord Halsbury considers the problems of animals on farms and in laboratories to be very different (16 August, page 534). There is however, an important case where the two are directly related. I refer to the neonate male chick (*Gallus gallus domesticus*) as an alternative to mammals for large-scale toxicity tests and other laboratory purposes. Farms in the United States alone have more than 275 million laying hens of strains developed to produce eggs at a minimum cost. Since the males of these strains have no commercial value (their meat is tough and stringy) they are destroyed after hatching. Thus, the males (cockerels) are a waste product, available in numbers exceeding 200 million per year in the United States alone. The chick offers advantages of low initial cost (approximately \$0.20 each compared with \$1.50 for mice and \$4.50 for rats) and low maintenance costs. Presumably, converting cockerels from a waste farm product to a source of income could also lead to lower prices for eggs.

There is ample precedent for laboratory uses of the chick, eg, Russell *et al.* (*Toxicol. Appl. Pharmacol.* 2, 558: 1960) compared the mouse and chick in toxicity determinations and Spooner and Winters (*Int. J. Neuropharmacol.* 5; 217; 1966) reported an extensive neuropharmacological profile of the chick. It would appear to be relatively staightforward for laboratories using large numbers of mammals to compare the chick with the mammalian model under their conditions. Similarities and differences will be found; each could prove useful.

A second suggestion for reducing the consumption of laboratory mammals is employment, where feasible, of the Dixon and Massey (*Introduction to Statistical Analysis*, McGraw-Hill, New York, 1957) "up-and-down" technique. This permits a 30-40% reduction in the number of animals required for an LD50 determination and is applicable to other tests, as well. A drawback which constrain applicability is that the effect upon a given animal must be known before the next animal can be tested.

While all living things should be protected from abuse, the Cruelty to Animals Act of 1876 recognised the differential attitudes of the public toward treatment of "cuddlesome pets" and of invertebrates. I suggest that resort to non-mammalian species, and to techniques which reduce the number of animals used in laboratories, might at least mitigate objection by the general public to the use of experimental animals.

Your faithfully,

ARTHUR CHERKIN

Sepulveda, California, US

Falsification of facts

SIR,—I have to disagree strongly with the letter by Lee Lorch (*Nature*, Vol 281, 13 September, page 98) on "Biased reporting of East European Science". My field of work is astronautics. In spite of all their activity, in this field and numerous international meetings, information from so-called Socialist bloc countries is nearly without value — ask any NASA international expert. There are some limited subject areas only (biomedical, and strictly scientific results), where my sweeping statement does not hold.

Any GDR citizen can visit the FRG, as far as the letter is concerned. It is the GDR which does not permit their citizens to travel freely. The accusation as stated by Larch is a gross falsification of the facts as they exist now since the shameful Berlin wall was built. Since this knowledge is widely available, I hold spreading of such disinformation to be irresponsible.

"Frustration and pessimism" is an exact description of the general mood in Soviet occupied Germany. I travel there quite frequently. Possibly Lorch does not speak German or succeeded in scaring his contact persons (easily done: they know the world they are condemnned to live in), so they were afraid of speaking freely.

Since I plan to continue travelling to East European countries, and to keep up the cordial personal relationship I enjoy with several scientists there, I ask that my name and affiliation be withheld.

ANON

Disillusionment with UK industry

SIR,—I wholeheartedly agree with the comments made in the article about Barry Francis and the engineering profession (9 August, page 442).

I became so disillusioned with British industry that I packed my bags and took my wife 4,000 miles west to the USA. Here I find that engineers enjoy a much better standing in society and those I encounter in industry hunger for the latest design and analysis techniques. Their appetite for using current research results contrasts so markedly with the conservative approach and outdated ideas so prevalent among British organisations. This is probably the reason why the UK iis termed Britain, rather than Great Britain. We no longer have the great engineers like Brunel, Watt and Stephenson and I don't see them materialising until many of the ideas indicated towards the end of the article are implemented.

Your faithfully,

BRIAN S THOMPSON

news and views

Direct imaging of atoms

from J. M. Thomas

EVER since Erwin Müller first demonstrated that individual atoms could be imaged (using field-ion microscopy, (FIM)) many scientists have endeavoured to view directly the atomic structure of molecules and crystals. The reasons for wishing to do so are numerous. First, some molecules, especially those involved in biochemical processes, are reluctant to crystallise, so that it becomes necessary to evolve methods for identifying and characterising certain segments, or the entire length, of isolated molecules. Second, crystalline solids are often composed of two or more finely intergrown phases and structures; and X rays and neutrons cannot solve the structure of such solids. Third, grossly defective (for example, highly non-stoichiometric or non-randomly stacked) solids defy structural elucidation by methods based on currently available techniques of X-ray crystallography. There is, therefore, exigent need for a tool that directly reveals the local rather than the averaged structure of solids. We should know more about dislocation cores, sub-grain boundaries and other extended defects, as well as interphase interfaces, if direct imaging of atoms were possible. Moreover, this achievement would have immense repercussions in metallurgy, medical and surface science as well as in solid-state physics and technology. Progress towards some hitherto inaccessible goals was reviewed at a recent symposium.*

Scanning transmission electron microscopy (STEM) is, in many respects, a natural complement to, and a direct descendent of FIM. Scattering of heavy atoms on light (carbon or boron) supports shows up readily when a minute pencil (<5 Å diameter) of electrons is scanned across a thin specimen; and there is no doubt from the work of A.V. Crewe (Enrico Fermi Institute, Chicago) and others that atomic resolution of isolated heavy atoms is readily possible. Unfortunately for biologically significant molecules the electron dose required to observe single heavy atoms (such as iodine, mercury or platinum which may be used to tag certain specific parts of a macromolecule) is at least an order of magnitude more than the dose which damages the macromolecule itself. Extensive beam damage to unstained molecules such as myokinase, valinomycin and vasopressin in STEM (F.P. Ottensmeyer, Ontario Cancer Institute) prompted A. Klug (MRC Laboratory of Molecular Biology, Cambridge) to ask whether the ashes of 'cremated' molecules are reminiscent of the original. As this question is still unresolved Klug argued cogently that biologists' time could be better spent trying to induce hitherto non-crystallisable macromolecules to form ordered two or three-dimensional aggregates so that they could be investigated by other methods.

For crystalline and defective solids STEM has two serious inadequacies: it is not easy, as pointed out by J.M. Cowley (Arizona State University), to orient specimens precisely, nor, at least on commercially available instruments, to record the diffraction pattern. These are essential prerequisites for high resolution structural imaging. It was, therefore, not surprising that most of the symposium was devoted to high resolution electron microscopy (HREM) by conventional (that is transmission) instruments.

V.E. Cosslett (University of Cambridge) described the performance of the high voltage (600 kV) high resolution microscope built as a collaborative venture between the Cavendish Laboratory and the Cambridge University Department of Engineering (W.C. Nixon). The minimum resolvable distance in a conventional electron microscope is proportional to $C_s^{1/4} \lambda^{3/4}$ so that improvements arise when the coefficient of spherical aberration (C_s) of the objective lens and the electron wave length, λ, are decreased (that is, accelerating voltage is increased). The strenuous attempts made to construct high-stability microscopes operating at 200, 600, 1,000 and 3,000 kV — all at present functioning in a few centres throughout the world — are therefore understandable. But how trustworthy is the projected image (assuming that the specimen suffers no appreciable beam damage or gives rise to minimal inelastic scattering)? When specimens are ultrathin, so that the weak phase object approximation holds true, interpretation is relatively straightforward, provided due regard is paid to the contrast transfer function of the objective lens. With thicker specimens multiple electron scattering is extensive and the observed image may bear no resemblance to the projected structural features of the object. Fortunately, a powerful procedure devised by Moodie (CSIRO, Melbourne) and Cowley and known as the 'multislice' method, enables the electron microscopic image — and its dependence on specimen thickness and the extent of lens defocus — to be calculated with considerable confidence. This method constitutes a means of matching computed with observed images. If the agreement is satisfactory, credence is given to the assumed structure that was fed into the calculation. The overall procedure of structure determination by electron microscopy is, therefore, akin to the trial and error method extensively adopted by X-ray crystallographers before the advent of direct methods. This restrictive state of affairs does not engender complacency, and is one of the reasons why theorists such as Moodie have developed a way, which he outlined, of achieving, under specific experimental conditions, direct inversion from the back focal plane.

L.A. Bursill (University of Melbourne) described how, by judicious use of 100-kV microscopes, structural resolution of less than 3.0 Å can be achieved. He demonstrated how novel features in certain naturally-occurring tunnel structures and incipient ferroelectrics are revealed by microscopic investigations. He also examined the question of 'model sensitiveness' of the image match in relation to the structure of the rather

*Nobel Symposium 47 on 'Direct Imaging of Atoms in Crystals and Molecules', was organised by P. Kierkegaard, A. Magneli, L. Kihlborg and M. Lundberg, and held at the IBM Nordic Education Centre, Lidingö, Sweden in August, 1979. The proceedings are to appear in a forthcoming issue of *Chemica Scripta* and also in a special publication edited by L. Kihlborg.

J.M. Thomas is Head of the Department of Physical Chemistry, University of Cambridge.

0028-0836/79/420523-02$01.00

enigmatic platelets known to occur (on {100} planes) in diamonds.

The trial and error method for determining crystal structures by HREM was strikingly illustrated by N. Uyeda (Institute for Chemical Research, Kyoto University) for a new phase of V_2O_5; by M. Sundberg (Arrhenius Laboratory, Stockholm) for a new tetragonal tungsten bronze consisting of pentagonal columns in a composition $W_{24}O_{68}$; by L. Kihlborg (Arrhenius Laboratory) for a fascinating range of intergrowth tungsten bronzes ($M_x WO_3$ with M = K, Rb, Cs and so on, and $X \leqslant 0.10$) consisting of hexagonal tunnels; and by S. Horiuchi (National Institute for Research in Inorganic Materials, Japan) on a new derivative of silicon nitride ($Si_3N_4.Y_2O_3$). None of these structures could have been solved by X-ray methods.

The image matching method was shown by J.M. Thomas (University of Cambridge) to be capable of distinguishing which of two possible new chain structures in silicate minerals exists as an extended, two- or three-dimensional defect inside nephrite jade, work which illustrates the power of the multislice method. A. Bourret (Centre d'etudes Nucléaires de Grenoble) likewise showed how structural details of one-dimensional faults in elemental semiconductors (Si and Ge) could be clarified by image matching; and S. Ijima (Arizona State University) has put the image matching approach to good use in his studies of the layer by layer build-up of graphitic carbon sheets. Even when no multislice calculations are carried out, structural insight may sometimes be gained by careful comparison of observed and 'expected' images, a fact vindicated by the work of O. Krivanek (University of California, Berkeley) and J.L. Hutchison (University of Oxford). The former, working with the Kyoto 500-kV microscope, showed that, as had been surmised, sub-grain boundaries in the Ge are made up of 5-and 7-fold rings: the latter has succeeded in clarifying the structure of both polytypic variants in certain perovskites and of Aurivillius phases. Horiuchi presented convincing proof that 1,000-kV high resolution images of $Nb_{12}O_{29}$ (a block structure) surpassed those taken with the best commercially available 100-kV microscopes. He also demonstrated that, by imaging ferroelectric crystals of $Bi_7Ti_4NbO_{21}$ along two or more high symmetry directions, the point group and hence the real space structure, may be determined directly. Resolution is sufficient to indicate, on the microscopic image, that the heavy atoms in the Aurivillius phase $Bi_2W_2O_9$ are not arranged on undistorted cubic lattice.

Two other studies illustrated the importance of high voltage HREM. N. Uyeda (Kyoto University) showed superb micrographs of hexadecachlorocopperphthalocyanine, which by adroit sample preparation (Uyeda *et al. J. appl. Phys.* **43**, 5181; 1972) will form pillars of overlapping molecules running essentially in the direction of projection. Apart from the central Cu and the peripheral Cl atoms, the outlines of the porphyrin rings, in this exceptionally beam-stable organometallic material, may be satisfactorily imaged. Thomas, with the aid of micrographs taken on the Cambridge 500-kV instrument (Jefferson *et al. Nature* **281**, 51; 1979) demonstrated how a point-to-point resolution of about 2.7 Å may now be comfortably achieved, thus making it possible to identify corner-sharing SiO_4 tetrahedra, and hence the backbone repeat patterns of the pyroxenoid minerals wollastonite and rhodonite.

It is most unlikely that solid state reactions, other than the kind described by R.J.D. Tilley (University of Bradford) who discussed the way in which electron irradiation generates so-called crystallographic shear (CS) planes in WO_3 when the latter, through oxygen loss, becomes progressively non-stoichiometric, will prove generally amenable to direct, *in situ*, investigation by HREM. In the words of J.S. Anderson (University College of Wales, Aberystwyth) the absence of 'eye-witness' procedures compels us to rely on the coroner's report in reconstructing the scene of the crime. With the aid of micrographs taken by his collaborator Sian Crawford Davies he gave a fascinating account of the quasi-homogenous oxidation reactions that take place within solids derived from the archetypal block structure Nb_2O_5, allegedly "the most flexible material in the whole of inorganic chemistry". Electron diffraction patterns of reactant and products in these systems are sometimes indistinguishable; but high resolution images enable one to chart (post event) the series of subtle, unit cooperative jumps (of the kind strikingly illustrated in other systems in a time-lapse movie film shown by H. Hashimoto, Osaka University) that may occur along a favoured line of atoms within these remarkably compliant materials. HREM studies clearly permit a 'projected' radial distribution pattern surrounding the locus of chemical reaction to be constructed in real space, from 'samples' consisting merely of a few tens of atoms. Post event rationalisation by J.V. Sanders (CSIRO, Melbourne) guided by HREM studies of hydrodesulphurisation catalyst particles has brought to light several unexpected facts, including the occurrence of encapsulating layers (a few atoms thick) of MoS_2. Comparable approaches have been adopted by Krivanek on silicon-silica interface. A. Howie (Cavendish Laboratory, Cambridge) dealt with amorphous materials, the radial distribution functions of which (extracted from X-ray data) do not adequately elucidate the local structure. Howie pointed out that HREM also runs into serious difficulty here, largely because of the problems stemming from the inherent unreliability of the projection procedure. Nevertheless, valuable progress has been made and Howie concentrated on how various experimental and processing (phase randomisation) approaches have been of value in the study of 'amorphous' metals, silicon and carbon.

Intermetallic systems were discussed from two viewpoints. S. Amelinckx (SCK/CEN, Mol), in an extensive series of unusual examples (dealing with alloys such as Au_4Mn, Au_5Mn, $Au_{11}Mn_4$) demonstrated how HREM, supplemented by selected area diffraction has greatly enlarged our knowledge of imperfectly ordered alloys. He emphasised how, under certain circumstances, there can be advantages in utilising superlattice spots to form relatively low power images rather than to push resolution to its limit (by taking the 'fundamental' diffraction spots). L. Stenberg's discussion (based on his work with S. Anderson) of some tetrahedrally close-packed alloys (such as Mo_3CoSi, Zr_4Al_3 and $MgCu_2$) strongly suggested that, as a result of advances in HREM, the structural inorganic chemist and the metallurgist will soon be brought closer. The concepts of CS, anti-phase boundaries and chemical twinning, which have proved valuable in interrelating structures among binary and ternary oxides seem to be equally useful in discussing these close-packed alloys. □

From ligands to legumes

from A. W. B. Johnston

THE interaction of atmospheric nitrogen with synthetic catalysts, and the interaction of *Rhizobium* with clover are two distantly related areas of research united by the phenomenon of biological nitrogen fixation. These two topics have been studied in depth by two eminent workers, Professor J. Chatt (Director of the Unit of Nitrogen Fixation, Sussex) and Dr P. S. Nutman (Head of the Soil Microbiology Department, Rothamsted) respectively, and to mark their impending retirements the Phytochemical Society of Europe organised a symposium* which included contributions on the whole spectrum of current nitrogen fixation research.

At the heart of the nitrogen fixation process lies the enzyme nitrogenase. W. H. Orme-Johnson (University of Wisconsin, Madison) considered the arrangement of the two metals, Fe and Mo, which are present in the protein subunit that is responsible for the binding and reduction of nitrogen. The Mo is present in a metal cluster that also contains Fe (MoFe

---

*An International Symposium on Nitrogen Fixation was held at the University of Sussex on 17-19 September, 1979, sponsored by the Phytochemical Society of Europe.

0028-0836/79/420524-02$01.00

cofactor); the majority of the Fe is present in Fe—S clusters that are in a highly reduced state and which are in a less exposed position than is the MoFe cofactor.

A point made by both J. Chatt and R. H. Burris (University of Wisconsin, Madison) was that nitrogenase has different affinities for the substrates N_2, H_2 and C_2H_2 depending on its oxidation state. Since the reduction of C_2H_2 to C_2H_4 is often used to assay nitrogenase activity it follows that it is not straightforward to extrapolate the values obtained from this assay to calculate absolute amounts of nitrogen that are being fixed.

Burris also referred to the fact that in *Rhodospirillum* and in *Azospirillum* the success in isolating the Fe-containing nitrogenase component is variable in different laboratories. It seems that there is an inactive form of the protein which can be activated by enzymatic removal of moieties (possibly adenine) and that the occurrence of the active or inactive forms depends upon the growth medium.

Nitrogenase needs a source of energy and electrons for reducing power. H. Haaker (Agricultural University, Wageningen) proposed that in *Azotobacter vinelandii* and in the bacteroids of *Rhizobium leguminosarum* the transport of electrons to nitrogenase depends upon the electrical component ($\Delta\psi$) of the proton motive force since there was a correlation between the value of $\Delta\psi$ and nitrogenase activity. In free-living nitrogen fixing bacteria, NH_4^+ is a potent repressor of nitrogenase but in the case of *Rhizobium* bacteroids, nitrogenase is relatively immune to NH_4^+ repression. Interestingly, the addition of NH_4^+ to *A. vinelandii* caused a drop in $\Delta\psi$ but the $\Delta\psi$ of *Rhizobium* bacteroids was immune to the addition of NH_4^+.

There are some bacteria that are doubly blessed in that they can fix nitrogen and can obtain the energy for fixation by photosynthesis. J. R. Gallon (University College of Swansea) considered whether in the case of blue green algae, photosynthesis could directly provide ATP and reductant to nitrogenase. Some evidence to support this came from the finding that inhibition of photosystem II rapidly inhibited nitrogenase activity in *Gloeocapsa*. However nitrogenase activity was quickly restored and it was suggested that this recovery was due to the switch on by another, non-photosynthetic, source of energy.

Bacteria that are fixing nitrogen liberate gaseous H_2 due to the reduction of protons by nitrogenase. Many species possess a hydrogenase that can be used to recoup some of the energy that would otherwise be lost. H. J. Evans (Oregon State University) discussed the hydrogenase system in *Rhizobium japonicum* in which the enzyme is sufficiently active to allow autotrophic growth on hydrogen as sole energy source. The fact that when hydrogenase-deficient mutants were used to inoculate soybeans the yields were about 30% less than when wild-type strains were used shows that the hydrogenase system is of real agronomic importance.

The developments in the genetics of nitrogen fixation were discussed by a number of speakers. The most detailed analyses have been on the *nif* gene cluster of *Klebsiella pneumoniae* and these were

Squirrels kill kids but are nice to relatives

from John Krebs

BELDING's Ground Squirrel (*Spermophilus beldingi*) conceals a vicious habit beneath its charming, furry coat. P. W. Sherman has studied a population of 250-300 of these little beasts high up in the Sierra Mountains of California since 1974, and he reported on some of his results at the XVI Ethological Congress.* The squirrels hibernate underground beneath the snow for about 8 months of the year and have a brief reproductive season during the months of May-August. Their life is a tough one as might be expected from such an extreme environment: 54-93% of juveniles and 23-68% of adults die during winter hibernation, and the survivors have to face the dangers of numerous nocturnal (coyotes, and bears) and diurnal (raptorial birds, weasels and coyotes) predators, as well as the risk of being run over by a passing car. These kinds of natural hazards are well known as causes of death in natural populations of many species, but more unusual is the fact that a considerable number of young squirrels die as a result of infanticide. About 8% of all young are dragged from their burrows by adult squirrels and killed before their mothers can come to the rescue. Sherman's detailed analyses of the causes and consequences of infanticide lead him to the following conclusions.

Adult females and yearling males are the commonest killers. Adult females kill when their own young have been destroyed by predators: the bereaved mother moves to a new place (choosing carefully to go to a place less susceptible to predator attack) and tries to kill the young of a mother in the area. If she is successful in killing young the female settles near the burrow of her victims. It seems, therefore, that infanticide by adult females is a form of competition: the female removes potential future competitors by disposing of her new neighbour's young. The young male killers, unlike the adult females, eat their victims, and Sherman suggests that the benefit derived is simply that baby ground squirrel is a good source of protein for a growing lad. A young male's future survival and reproductive success in this highly polygynous species depends heavily on fighting ability and hence body size (Sherman in *Natural selection and social behaviour: recent research and new theory.* (Alexander & Tinkle eds.) Chiron Press 1979).

Thus infanticide is far from being a pathological behaviour shown by a few squirrels under abnormal conditions; it is a normal part of the day-to-day business of competition and survival. Female squirrels with young are highly territorial during the period in which their infants are helpless to defend themselves, and mothers with large territories have the lowest risk of infanticide, which suggests that territory defence might be an anti-infanticide device.

Belding's Ground Squirrels are not, however, universally nasty: close relatives are nice to each other. The squirrel society is matrilineal. Females pass on bits of their defended home area to daughters while males disperse well away from home soon after weaning. Sherman's accurate data on kinship enabled him to show that close female relatives cooperate with each other in a number of ways. They share parts of their territories, do not attack each other very often, and help each other in guarding their burrows against infanticidal intruders. Mothers also put themselves at a demonstrable risk when a predator approaches by giving alarm calls to warn close relatives of the danger (Sherman *Science* **197**, 1246; 1977). Squirrels without close relatives in the vicinity (males and transient females) do not give alarm calls, which is consistent with the fact that they do not stand to make a genetic profit by self-sacrifice.

Sherman's unique and impressive data show that altruism (or nepotism as he prefers to call it) occurs between close relatives. This is to be expected since an altruist's genes are propagated not just through children but also through other relatives, and some would argue that Sherman's data are a good test of the theory of kin selection. In a sense, however, the theory is not testable. It is a logical generalisation of the theory of Natural Selection and is not one of a number of alternative, refutable hypotheses. However, an example of the kind of interesting question which arises from kin selection theory is Sherman's observation (*Nat. Hist.* **88**, 80; 1979) that while mothers, daughters and sisters show nepotism towards one another, more distant relatives such as aunts and nieces or grandmothers and granddaughters do not. As Sherman puts it, the reasons for this limit to nepotism remain an enigma.

John Krebs is a Lecturer in Zoology in the Edward Grey Institute of Field Ornithology, University of Oxford.

*The XVI International Ethological Congress was held in Vancouver, BC, Canada, 18-27 August, 1979.

0028-0836/79/420525-01$01.00

considered by M. J. Merrick (Unit of Nitrogen Fixation, Sussex). Fourteen genes have been identified and these are organised into eight transcriptional units. A useful tool in the study of gene control in this system involves the insertion into the different *nif* operons of a derivative of bacteriophage Mu carrying the structural genes but not the promoter of the *Escherichia coli lac* operon. Thus expression of any *nif* transcriptional unit can be determined by assaying β-galactosidase production. By such means it was shown that when *K. pneumoniae* was derepressed for *nif* expression different *nif* genes were turned on at different times. The allocation of particular proteins (seen on two-dimensional gels) to particular *nif* genes was demonstrated in posters by J. Houmard (Institut Pasteur) and by W. Klipp (University of Erlangen). Klipp also showed that the DNA corresponding to the *K. pneumoniae nif* region was significantly more dense than the typical value for the chromosome of this species and is also flanked by two sets of inverted repeats. It was suggested that the *nif* genes may have been acquired relatively recently by recombination with some other bacteria.

The close relationship of *nif* DNA from different nitrogen fixing species in widely separated taxonomic groups was in fact demonstrated by F. Ausubel (Harvard University). A segment of the *nif* operon containing *K. pneumoniae* structural genes for nitrogenase has been cloned and been found to hybridise with DNA from 8 different nitrogen fixing species but not to 12 other, non-fixing species. In the case of *R. meliloti,* hybridisation was specifically with plasmid DNA, a conclusion also supported by data presented by A. Kondorosi (Hungarian Academy of Sciences, Szeged). J. E. Beringer (John Innes Institute, Norwich) reported that in *R. leguminosarum,* some of the genes that are required for nodulation and for fixation within the nodules have been located on the same resident plasmid found in a strain of this species.

The past 10 years have seen a great rise in interest in biological nitrogen fixation, stemming largely from the awareness that the production of commercial nitrogenous fertiliser makes significant demands on fossil fuel energy. This interest has been reflected in the real developments that have been made in many areas of research in this field and these were amply demonstrated in many of the contributions that were given at the symposium. ☐

A. W. B. Johnston is at the John Innes Institute, Norwich.

How do toxins penetrate cells?

from R. C. Hughes

THE death of the Bulgarian broadcaster, Georgi Markov, apparently by a ricin bullet, received considerable press coverage recently. In less sombre vein the cytopathological effects of ricin and other toxins are of wide interest since they hold out some hope for site-directed killing of tumours and may also throw some light on the mechanism of action and entry into cells of molecules such as hormones and growth factors.

At a recent workshop meeting*, F. Stirpe (Instituto di Patologia Generale, Bologna, Italy) described the effects of injection of ricin into rats as severe necrosis of sinusoidal (Kupffer) cells of the liver and of the red pulp of the spleen. Abrin and modeccin are related toxins, binding to similar glycoprotein receptors as ricin. While modeccin affects the liver, abrin specifically brings about severe necrosis of acinar pancreatic cells. Like many toxins, ricin, abrin and modeccin bind to cell surface recptors, enter the cell and exert a cytoplasmic effect, in these particular cases by inhibition of protein synthesis. All three toxins apparently block protein synthesis at an identical site on 60 S ribosomes and are structurally very similar, consisting of two polypeptide subunits. One subunit (B chain) binds to cell surface galactose residues following which the toxic A subunit is taken up into the cell and transported to the ribosomes (see Olsnes in *Transport of Molecules in Cellular Systems* (ed. Silverstein) Dahlem Conference, Berlin, 103;1978). Since the A subunits of ricin, abrin and modeccin are biologically indistinguishable the interesting target specificity described by Stirpe must be due either to small differences in the preferred surface receptors for each toxin expressed on different cell types or to differences in the steps subsequent to binding. Stirpe suggested that these steps may include processing or degradation of the toxins, and such processing may be essential in mediating cytotoxicity or if carried to excess, may destroy biological activity.

The mechanisms by which bifunctional molecules such as ricin traverse the cell surface membrane and transport the toxin portion of the molecule to the cytoplasmic site of action are poorly understood. A. M. Pappenheimer (Harvard University) presented compelling evidence for the direct transfer of the toxic principle of diphtheria toxin. Diphtheria toxin (a 62K protein) contains hydrophobic peptide sequences in the B region (40K), located at the C-terminal of the whole toxin molecule (P. Falmagne, Université d'Etat à Mons, Belgium). Presumably diphtheria toxin first binds to surface receptors (as yet unidentified) and then inserts into the phospholipid bilayer by more stable transverse associations mediated through the hydrophobic peptide sequences (see Boquet *et al. Proc. natn Acad. Sci. U.S.A.* **73,** 4449; 1974). Pappenheimer believes that such an association requires the cleavage of a C-terminal sequence of the B fragment which possibly is facilitated by the unusually high incidence of basic residues in this region. Additional features of diphtheria toxin action on sensitive cells comes from study of mutant proteins (Pappenheimer). Toxin (CRM 45) of abnormally low molecular weight (45K) isolated from a chain-terminating mutant contains an enzymically active A fragment (22K) but lacks much of the B region sequence required for interaction with surface receptors. CRM 45 toxin contains the hydrophobic sequence, however, and is about 1-2% as toxic as normal toxin when injected into chickens and is equally toxic when injected into the brain of mice where the cells chiefly affected are Schwann cells. Fragment A itself, lacking the hydrophobic sequence of CRM 45, is at least 100-fold less toxic in this system emphasising the importance of the hydrophobic sequence in mediating toxicity. Pappenheimer suggests that the intact diphtheria toxin, the CRM 45 protein and fragment A are taken up into cells by different mechanisms of steeply decreasing efficiency. Evidently even the latter inefficient uptake is sufficient to kill a cell because it had been calculated that one or two toxin molecules in the cytoplasm are sufficient.

This high sensitivity probably also explains the recent success in synthesis of hybrid toxic molecules. Despite one negative result of Chang *et al.* (*J. biol. Chem.* **252,** 1515; 1977) who found no killing of mammary cells by a diphtheria A subunit — human placental lactogen complex, more recent reports have shown that diphtheria A subunit coupled with concanavalin A (Gilliland *et al. Proc. natn Acad. Sci. U.S.A.* **75,** 5319; 1978), *Wisteria floribunda* lectin (Uchida *et al. J. biol. Chem.* **253,** 6307; 1978), and antilymphocyte globulin (Thorpe *et al. Nature* **271,** 752; 1978) or ricin A subunit coupled with human gonadotropin (Oltmann & Heath *J. biol. Chem.* **254,** 1022; 1979) or concanavalin A (Yamaguchi *et al. J. natn Cancer Inst.* **63,** 1387; 1979) are cytotoxic, although at high doses and over rather long periods. Presumably, the processing of the conjugates is mediated after binding of the surface binding ligands and leads to penetration of the toxic A subunits. It is not clear whether this uptake

*The Workshop 'Toxins with intracellular targets' was organised by S. Olsnes (Norsk Hydro's Institute for Cancer Research, Oslo) and P. Boquet (Pasteur Institute, Paris) as part of the 6th International Symposium on Animal, Plant and Microbial Toxins held on 19-24 August, in Uppsala, Sweden.

0028-0836/79/420526-02$01.00

is similar to that described for the intact diphtheria toxin or is more closely analogous to the less efficient mechanisms by which CRM 45 or diphtheria fragment A penetrate the cell.

The uptake of ricin into cells may proceed in a way analogous to the Pappenheimer model for diphtheria toxin. Ricin undergoes a conformational change after binding to oligosaccharide receptors that may facilitate direct transfer, for example by exposure of hydrophobic segments. S. Olsnes (Norsk-Hydro's Institute for Cancer Research, Oslo) and R. C. Hughes (National Institute for Medical Research, Mill Hill) showed that ricin action is inhibited at low temperatures. Mosquito cells and baby hamster kidney cells are protected significantly from ricin toxicity at 28°C although binding to cells and inhibition of protein synthesis in cell free systems are as effective at 28 as at 37°C (T. Butters & Hughes). Since mosquito cells grow optimally at 28°C the temperature effect is likely to be attributed to the ricin molecule itself, possibly in the conformational change mentioned above. One cold sensitive structure could be eliminated as contributing to the temperature effect. Colchicine, which disrupts cytoplasmic microtubules in hamster fibroblasts, has no significant 28°C effect on ricin toxicity. Cytochalasin B does protect cells after prolonged treatment before the challenge with ricin suggesting a possible involvement of microfilaments in ricin penetration into cells.

Bundles of microfilaments directly under the surface membrane are believed to have a role in receptor-mediated pinocytosis by contraction of the plasma membrane containing the surface absorbed ligand. However, the role of endocytosis in mediating entry of toxins is still controversial. Receptor-mediated endocytosis of toxins has been observed directly in several systems but such experiments use very high levels of toxins for visualisation, usually much higher than the cytotoxic dose. It is then not clear whether the toxin molecules seen enclosed in endocytotic vesicles within the cytoplasm are those responsible for the toxic effect by leakage of toxin from just one vesicle. Endocytosis is clearly involved in uptake of lipoproteins into cells at the specialised surface sites, enriched in the specific receptors, known as 'coated pits' (Goldstein *et al. Nature* **279**, 679; 1979). However, lipoprotein uptake is geared to the lysosomal degradation of proteins and release of cholesterol and it would be premature to assume similar mechanisms operating in toxin action.

Nonetheless, J. L. Middlebrook (US Army Medical Research Institute of Infectious Diseases, Fort Detrick) showed that both diphtheria toxin and *Pseudomonas* exotoxin A may enter some cells by receptor-mediated endocytosis. Local anaesthetics and lysosomotropic agents such as choloroquine protect cells from toxicity. Similarly, G. T. Keusch (Tufts University, Boston) showed that lysosomal stabilisers or drugs affecting microfilament or microtubule function inhibited the effect of *Shigella* exotoxin on sensitive cells while DEAE-dextran, a stimulator of endocytosis, significantly increased the cytotoxic response of the cells to the toxin. Keusch proposed that a limited degradation of *Shigella* exotoxin in the lysosomes is a necessary step in cytotoxic action, which is reminiscent of the proposals for ricin by Stirpe and for diphtheria toxin by Pappenheimer. Such processing seems to be a common feature of many models of toxin action. Clearly, lysosomes are specialised for such protein degradation but specific limited proteolysis at cell surfaces is still an attractive alternative.

The evidence at present suggests strongly that toxin action mimics the normal mechanisms of action of hormones and growth factors. In some cases similar or identical surface receptors are involved and it is quite likely that the subsequent steps in mediating these diverse biological effects may turn out to be similar. ☐

Meteoritics — life begins at seventy

from A.E. Fallick and C.T. Pillinger

IT is now known that nearly 20% of the naturally occurring elements have isotopic variations which are not the result of nuclear reactions within the Solar System, and therefore it was something of a novelty for the recent meeting of the Meteoritical Society in Heidelberg* to close without a report of a new isotope anomaly. However, interest in the subject is not declining. In fact the opposite is true, and accordingly two reviews were devoted to this exciting area, G.W. Lugmair (San Diego) dealing with the state of the art and W. Hillebrandt (Munich) considering the challenge presented to theories of nucleosynthesis.

The group led by Peter Eberhardt (Physikalisches Institut, Berne) has perhaps best demonstrated the painstaking approach now needed to track down the location of anomalies. Since 1974 various members of this department have been investigating the occurrence of a component of the rare gas neon (called neon-E) in a number of meteorites. After an extremely detailed study starting from 6 g of the Orgueil carbonaceous chondrite, M.H.A. Jungck and Eberhardt have isolated a few hundred micrograms of an unidentified, but probably carbonaceous, component which on stepwise heating releases neon having an isotopic composition $^{20}Ne/^{22}Ne = 0.008$ and $^{21}Ne/^{22}Ne = 0.0006$, which means that it is practically pure ^{22}Ne. One possibility is that neon-E is the daughter product of ^{22}Na, an isotope with a 2.6 year half-life.

Much interest is still focused on the Allende meteorite. For example, E.K. Jessberger and E. Dominik (*Nature* **277**, 554; 1979) recently reported a potassium-argon age of 5.08×10^9 year for an Allende inclusion. Isotopic measurements on potassium by W. Stegmann and F. Begemann (Mainz) have shown a composition within ½% of the terrestrial value, which discounts the possibility that the extraordinarily high age is an artefact explicable in terms of an enhancement in ^{40}K.

Isotopic anomalies are certainly no longer confined to meteorites. Various workers, including J.F. Kerridge (Los Angeles) and R.N. Clayton (Chicago), have for some time been advocating a secular change in the nitrogen isotopic composition of the solar wind. M.H. Thiemens and Clayton now report a new low δ value of −110‰ (relative to atmospheric gas) for nitrogen in an Apollo 17 lunar soil. Whilst astrophysicists are presumably aghast at having to explain nitrogen isotopic fluctuations of 30% in the source region of the Sun, Clayton admits that the onus is on the experimenter to verify conclusively the data.

Also on the Moon, an examination of the siderophile trace element pattern of Apollo 17 black glass spheres by J.W. Morgan (Reston) suggests that these glasses are not purely of volcanic origin, as has been proposed. The relative abundance of seven out of eight elements points to the possibility that a particular type of iron meteorite splashing into a lava lake could have been partly responsible. Speaking from the floor, Ed Anders (Chicago) recalled that when such an origin was proposed a number of years ago there was a degree of incredulity amongst the audience, but he felt the evidence now presented had reopened the debate.

Inevitably a number of 'old faithfuls' reared their heads. Although first recognised in 1802 and named in 1863, chondrules remain an enigma. Klaus Keil (Albuquerque) eloquently dismissed as many origins for these as there are students of the subject minus one — and in as many seconds — during his review of the field. On the basis of textural and chemical evidence, and laser-induced melting simulations, he favours a secondary impact origin rather than some primary process. New food for thought for chondrule students, however, came from Kurt Fredriksson (Smithsonian Institute) who, because of improved techniques in manufacturing ultrathin polished sections, was able to observe a carbonate inclusion in the centre of a chondrule from the Allegan meteorite.

In the new areas of endeavour it was good to see a number of papers devoted to

recently discovered Antarctic meteorites. One interesting point made by L. Schultz (Mainz-Paris consortium) was that a sample collected in the Allan Hills must have had a preatmospheric radius of only 1-2 cm. It was previously thought that such small samples did not survive passage to Earth. At the other extreme several investigators, including members of a Chinese delegation, described work on the Kirin meteorite, a four-tonne chondrite which fell recently in the People's Republic. A survey of the ancient literature of China by Tu Guangzhi (Institute of Geochemistry, Guiyang) reveals many credible records of phenomena attributable to falling meteorites, the earliest being in 2133 BC. We hope that China's future participation in meteoritics will be as prolific as its past.

Another hope for the future is the planned chemical investigation of cometary dust particles during possible fly-by of Halley's comet and rendezvous with Temple 2. B.-K. Dalmann (Max Planck Institut für Kernphysik, Heidelberg) described various experiments for the secondary ion mass spectrometer on the rendezvous mission, including an attempt to measure stable carbon isotope ratios. Another possible source of cometary debris for analysis, suggested by Dave Brownlee (University of Washington, Seattle), is the collection of micron-sized particles from the stratosphere by U2 aircraft. Perhaps study of these grains could reveal the carbon isotopic ratio of comets if a sufficiently sensitive technique were available.

Finally as an encouragement to those of us who have yet to make a significant contribution to science, the Meteoritical Society chose to honour Paul Ramdohr (Max-Planck-Institut für Kernphysik, Heidelberg) with its Leonard Medal. Although Professor Ramdohr claims an interest in meteoritics from his first months as an undergraduate in 1909, he did not commence the work for which the medal was awarded until after his 'retirement' in 1960 at the age of seventy! □

Is there anyone out there?

from J. Tarter and B. Zuckerman

"WHERE are they?" This question attributed to Enrico Fermi held centre stage during a full day symposium on 'Strategies for the Search For Life in the Universe' at the XVII General Assembly of the International Astronomical Union.

The first topic under discussion was 'N' the number of communicative civilisations that currently exist in our Milky Way Galaxy. I. Shklovsky (Sternberg Astronomical Institute) suggested that the choice of a value for N may be a very large number ($\geqslant 10^9$). Considerably less optimistic was M. Hart of Trinity University who argued that N is likely to be very small (~ 1). Hart pointed out that a calculation of N by means of the so-called Drake equation is essentially impossible owing to the orders of magnitude uncertainty in many of the terms. A better way to estimate N, according to Hart, is to assume some value for N and enquire about its effect on observables. In particular, he asked, if N is very large then, "where are they?". That is, if there are a million civilisations in the Milky Way then at least one of them would have colonised our Solar System by now since the time to colonise the entire Galaxy, with nuclear rockets for example, is far less than the age of the Galaxy. Kuiper referred to Fermi's question as the "big gun in a small arsenal" of arguments in support of $N \sim 1$.

F. Drake of Cornell University occupied the middle ground. The negative results of searches for radio beacons, and radio astronomy in general, imply that N is not very large. But he also argued against $N \sim 1$ and the interstellar colonisation idea on the grounds that colonisation is not cost effective. A better way to improve the quality of life per dollar spent is to remake your own planet and/or solar system. This idea was countered by Kuiper who argued that colonisation would increase the raw material base and by S. von Hoerner of the US National Radio Astronomy Observatory who remarked that luxury makes life nice but "luxury is never cost effective".

P. Morrison of MIT summarised the discussion of N, noting that little new has appeared on the scene since he and Cocconi published the first SETI paper in *Nature* 20 years ago. We have only four 'facts' to go on: Hart's 'fact A' (they are not now here on the Earth), the negative results of radio searches, the presence of life on the Earth, and its absence on Mars. We are still not in quantitative control of the problem, Morrison observed, since calculations of N give 2 σ limits between 10^2 and 10^9. As he did so long ago, Morrison argued for modest experiments with existing radio telescopes to bound the problem observationally.

The second session was devoted to radio searches for extraterrestrial intelligence (SETI). V. Troitsky of the Scientific Radiophysical Institute in Gorky outlined Soviet plans for a fully automated and continuous SETI programme using widely separated antennas on the ground linked with a 10-m dish in space. Troitsky and Shklovsky were two members of a sizeable Soviet delegation at the General Assembly which convened in August in Montreal, Canada. B. Zuckerman (University of Maryland) described recent and ongoing SETI programmes in the USA and Canada and S. Gulkis (Jet Propulsion Laboratory) summarised a SETI programme proposed for inclusion in the NASA FY'82 budget. This 6-year programme, a joint endeavour between NASA's Ames Research Center and JPL, would attempt to optimise the probability of detection using existing radio telescopes in conjunction with new low noise receivers and extremely large digital spectrum analysers.

Jesse Greenstein chaired a discussion on the prospects for detection of simple forms of life elsewhere in the Solar System and the discovery of extrasolar planets. He seemed to respond to Morrison's lament over the lack of progress, noting that SETI as a science was in the awkward position of being "respectable but not yet funded". At least in the case of planetary detection, it was clear that funding would produce definitive answers to a limited set of interesting questions in the near future. G. Soffen from NASA-HQ reviewed the biological ramifications of "life as we know it" and the possibility of recognising "life as we don't know it". T. Owen from the State University of New York pointed

Change of Colour in Frogs

It is certainly a common opinion in this part of the country that when frogs become of a bright yellow colour fine weather may be expected. The brightness of colour can scarcely be due to the presence of sunlight, for frogs of a bright yellow may frequently be found in cellars, wells, and other dark places. Throughout the past summer and up to the present time, I have noticed that the frogs in this neighbourhood have been of an extraordinarily brilliant yellow tint. Again and again have I heard the country people, working in the hay or corn fields, under the unbroken canopy of cloud, remark — "We must be going to have fine weather now, for look at the colour of the frogs." These forecasts proved the reverse of successful.

At the commencement of "the rains" (say, beginning of June), in the island of Bombay, after the first showers, when a little water lodges in the depressions of the old-quarry tanks, the frogs issue from the crevices of the trap-rock to spawn, when the *males* (some of which are 18 inches in length from tip of toe to end of digit) assume a bright mustard-yellow colour, while the females remain brown as usual; and this change of colour takes place so rapidly, and the frogs are so numerous, that, with the falling of the showers, the bottom of the quarry becomes suddenly yellow.

From *Nature* **20**, Oct 16, 580; 1879.

out the spectroscopic potential for detecting abundant quantities of O_2 or other disequilibrium atmospheric constituents, indicative of the presence of some form of life.

As for finding extrasolar planets, indirect schemes based on state-of-the-art astrometry, interferometry, radial velocity measurements and the wide field CCD cameras on the Space Telescope were described in turn by G. Gatewood (Allegheny Observatory), D. Currie (University of Maryland), I. McLean (University of Arizona) and W. Baum (Lowell Observatory). Comparing these techniques D. Black of Ames noted their complementarity due to the intrinsically different dependences on stellar mass and planetary size and orbit sampled by the various methods. He concluded that the milli-arcsecond spatial resolution and the 10 m s^{-1} velocity precision needed to detect a Jupiter-Sun system in the local solar neighbourhood are at hand. However direct detection schemes in the visible or infrared and the micro-arcsecond/10 cm s^{-1} precisions required to detect an Earth-Sun system must await the next generation of instrumentation. While this entire field looks extremely hopeful it was suggested by the participants that it may require a 'dialectic unification' to get two different groups of astrometrists to agree on the question of the existence of a planet orbiting around Barnard's star. ☐

The answer lies in the blood

by Mary Lindley

Tiny, dried up bloodstains of indeterminate age may not be the biochemical geneticist's dream, but for those who work in the forensic world they are routine specimens. The continual challenge of obtaining more information from less and less material was in the minds of delegates at a recent international gathering of forensic haemogeneticists*. With the elucidation of the kinetics of the reaction between antigen and antibody, it has become possible to identify blood group antigens immunologially with greatly improved efficiency. P.J. Lincoln (London Hospital Medical College) explained that by careful manipulation of *p*H, ionic strength and the amount of antiserum used, it is possible to identify an antigen on a single bloodstained thread, so that even a minute bloodstain can provide sufficient material to examine for several antigens. Sixteen red cell antigens, including those of the A,B,O and Rhesus systems, can be identified by an elution technique. The thread is incubated with a specific antibody, which is subsequently eluted and examined by a sensitive agglutination test. Antibodies corresponding to the antigens in the bloodstain bind to the dried blood, are recovered by elution and detected in the eluate. The serum markers of the Gm and Km system, determining differences in immunoglobulin constant regions, can be detected by inhibition tests. Antiserum is incubated with the bloodstained thread and if antigen is present, the antibodies are absorbed and the activity of the antiserum inhibited.

Some antigens remain detectable by these methods for only a short time, while others such as ABO can be detected after many months, or even years. The age as well as the amount of material available thus determines the antigens used to establish the origin of a bloodstain. A combination of a few of these antigens, Lincoln said, can distinguish between the bloods of two individuals in nearly every case.

Inhibition tests also form the basis for detecting HLA antigens in bloodstained thread, described by D. Hodge (London Hospital Medical College). This work is very preliminary and so far only the HLA-A antigen has been tried, largely because it is well represented in European and Caucasian populations and because good antisera were available. Best results have been obtained when several antisera have been used in parallel to type a stain. Even assuming success, Lincoln said, HLA typing of bloodstains is unlikely to become routine in casework in the near future but it could provide a valuable specialised proceedure.

More than 20 systems of enzyme polymorphisms can be identified in bloodstains as a result of recent improvements in electrophoresis and the introduction of isoelectric focusing, described by B.J. Culliford (Metropolitan Police Forensic Science Laboratory, London). Using 18 such systems, he and his colleagues know that when they identify a bloodstain according to its profile of enzyme polymorphisms it has come from no more than one in 1,800 people. When a specimen is very meagre, it can be tested sequentially for two or more systems. G.B. Divall (Metropolitan Police Forensic Science Laboratory) said that one piece of bloodstained thread can be used first to identify Gm, Km and enzyme polymorphisms by electrophoresis, and then A,B, and O by an absorption-elution technique.

Early results reported by B. Brinkmann (Institüt für Rechtsmedizin, Universität Hamburg) suggest that measurement of enzyme activities could be a guide to the age of a bloodstain. In test bloodstains the activities of acid phosphatase, phosphoglucomutase, adenylate kinase, adenosine deaminase, and phosphogluconate dehydrogenase declined, rapidly at first and then more slowly, at rates correlated with the enzyme phenotype and the time and temperature of previous storage. Much more has to be learnt about the effects of environmental conditions, however, before any routine application for assessing the age of bloodstains would be possible.

J.L. Thomsen (University Institute of Forensic Medicine, Copenhagen) reported his success in identifying the Y chromosome of leukocytes extracted from bloodstains. He has managed to obtain sufficient leukocyes to treat them with the fluorescent stain that reveals the Y, the only chromosome identifiable in dead cells. In spite of the difficulty of the procedure, Thomsen suggested that it could offer a reliable means of sex determination in blood. His claim to have obtained no false positives was greeted with some scepticism however.

The nucleolus at Weimar

from E. G. Jordan

THE workshop* opened with an outline of our present understanding of nucleolar structure given by M. Bouteille (University of Paris) in which he emphasised the importance of the identification of the discrete pale-staining islands of the nucleolus as the nucleolus-organising regions. These areas which have been given many different names in the past, are clearly distinguishable from the two major parts of nucleoli, the fibrillar and the granular components. P. Hernandez-Verdun (University of Paris) showed that in micronuclei induced with colchicine treatment no organisation of nucleolar material into nucleoli occurred in the absence of such a pale-staining 'fibrillar centre', hereby shown to be functionally related to the nucleolus organisers. C. Mirre (Faculty of Medicine, Marseille) reported that the number of fibrillar centres contributing to the generation of a new nucleolus in meiotic cells was the same as the number of organising chromosomes involved. Many workers agreed that the use of the silver staining procedure identifies these 'fibrillar centres' and hence the nucleolus organisers. However, the specificity of the silver stain is known to depend critically on the conditions used and some workers reported silver staining of structures other than nucleolus

---

*The Sixth European Nucleolar Workshop was held in Weimar on 1-6 July, 1979 under the auspices of the European Cell Biology Organisation (ECBO) and was organised by Dr. S. Rosenthal of the Central Institute of Molecular Biology, Academy of Sciences GDR, Berlin.

0028-0836/79/420529-02$01.00

organisers, while Y. Daskal (Baylor College of Medicine, Texas) reported that the group of H. Busch had now identified a nucleolar acidic protein with especially high affinity for silver.

The question of the function of the nucleolus-organising regions was raised by G. Goessens (University of Liege, Belgium) who has shown by autoradiography that these regions, or at least those parts which can be identified as pale-staining islands within the nucleolus, are not themselves the sites of RNA transcription. This was further emphasised by W. Franke (German Cancer Research Centre, Heidelberg) who described a specific fibrillar nucleolar skeleton which constitutes a large proportion of the nucleolar material and may be a component of the structures identified as organisers.

The general importance of skeletal structures in understanding the organisation of chromatin and transcriptional processes in the nucleus was emphasised by R. Hancock (Swiss Cancer Institute, Lausanne) who presented evidence to show that the chromatin of the nucleus is arranged in loops which are anchored by regions of repetitive DNA sequences into a peripheral nuclear skeleton consisting of protein distributed in a broad zone around the nuclear envelope. The proteins, which include some prominent polypeptides with molecular weights in the 65,000-75,000 region, are responsible for maintaining a condensed network of chromatin fibrils after the removal of histones, nuclear membranes and pore complexes. The chromatin loops extending from this peripheral skeletal layer ranged from 20-150 kb with an average of about 53 kb, and were displayed using the Kleinschmidt spreading technique. The region of transcription could be identified by the presence of nascent transcripts and was usually found a good distance from the region containing the anchorage sites. The possible relationship of this peripheral skeletal structure with matrix components of the nuclear interior was discussed by I. Zbarsky (Academy of Sciences, Moscow). The possibility that a large part of the nucleolus is constituted by a proteinaceous matrix provides a cautionary note against oversimplified interpretations of nucleolar organisation. While it is clear that in active nucleoli the densely stained fibrillar component surrounding the fibrillar centres of the organiser is the site of transcription, the arrangement of structures involved in maturation and processing stages and their possible association with a nucleolar skeleton are still questions for the future.

Structure of rRNA genes

Intervening sequences (introns) in rRNA genes have been well-characterised over the past few years. At this meeting R. Renkawitz-Pohl (University of Dusseldorf) demonstrated two types of intervening sequences in the rDNA of *Sciara coprophila*, suggesting that the three adjacent groups of ribosomal genes in this organism may differ with respect to these sequences. Heterogeneity between different nucleolar organisers in *Drosophila hydei* was reported by W. Kunz (Dusseldorf). Here the two organisers in the Y chromosome lack a 5.5 kb insert which is found in the rRNA genes of the X chromosome.

The complete 407 bp sequence of the 25S rRNA intervening sequence from *Tetrahymena pigmentosa* was reported by M. A. Wild (Yale University). The intron-exon junctions have been identified and are completely different from those reported for mRNA inserts, which strongly suggests a different splicing enzyme for rRNA. In addition, the position of the splice point is unequivocal as there are no directly repeated sequences at the junctions as there are in mRNAs.

Direct evidence that such a ribosomal RNA gene insert (in this case from the related species *T. thermophila*) is transcribed and processed was provided by W. A. Eckert (University of Heidelberg). The intervening sequence seemed to be removed rapidly as the first step in processing, since the insert was only found in about 20-30% of the largest precursor rRNA fraction. This also suggests that the excising activity resides in the nucleolus.

Homologies between the rDNA of widely different organisms were shown by R. Gourse (Brown University, Providence). By hybridising labelled cloned restriction fragments he found that the rDNA immediately adjacent to the *Tetrahymena* intron was homologous to fragments at similar positions in the rDNA of yeast and *Dictyostelium*. In addition, homologies between the latter two organisms were present at the 3′ end of the region coding for 18S rRNA.

R. Bach (University of Geneva) also reported that several strongly conserved regions had been found in cloned rDNA fragments from three species of *Xenopus*. These conserved regions include the 3′ end of the 40S rRNA precursor and, interestingly, a 30 bp region about 100 bp away from this end. The region immediately preceding the beginning of the precursor was also highly conserved, but, aside from the first few bases, the 5′ end of the precursor itself was not. These findings indicate that the search for 'promoter' sequences may soon be successful.

Interest in the regulation of transcription has led to studies such as those reported by I. Financsek (Institute of Radiobiology, Budapest), who has cloned rDNA fragments from Novikiff hepatoma cells. One clone bound *E. coli* polymerases *in vitro*, and is thought to contain the promoter. Along similar lines, M. Muramatsu (Cancer Institute, Tokyo) has cloned a long mouse rDNA fragment which extends from the middle of the 18S rRNA gene region through the transcribed leader of the pre-rRNA, and probably also contains the promoter.

Such studies are being complemented by functional assays of rDNA in eukaryotic cells, such as its microinjection into amphibian oocyte nuclei.

Pre-mRNA and informosomes

The fate of the primary RNA transcript was discussed in relation to the concepts of pre-message, informosomes and the ubiquitous perichromatin granules. Some equivalence in secondary structure of adjacent RNP fibrils in spread *Drosophila* germ cell chromatin was reported by K. Glatzer (University of Dusseldorf) who calculated a DNP/RNP length ratio of 4.6 showing a similar foreshortening previously described in nucleolar genes. The addition of protein to the early transcripts is thought to result in the formation of granules or particles of RNP. There were two extensive reports on the 'perichromatin granules', PCGs. E. Puvion (Cancer Research Institute, Villejuif) showed how the numbers of these 40 nm granules with their characteristic clear zone or 'halo' could be increased dramatically by reducing the RNA processing activity of cells using cadmium chloride. The PCGs were found all around the blocks of dense chromatin, that is, the site where RNA could also be shown to accumulate by autoradiography at the electron microscopic level. Under these conditions the normal migration of label to the interchromatin spaces was arrested. These granules could also be shown to be connected to chromatin fibrils by slender stalks, using either spread preparations or thin section procedures, which may further indicate that they are modified products of transcription.

Y. Daskal (Baylor College of Medicine, Houston) has isolated one major polypeptide of 40,000 molecular weight and two minor ones (31,000 and 38,000 molecular weight) from PCGs. Interestingly, PCGs also contain a characteristic 4.7S RNA. While these findings are all compatible with the concept that PCGs are a sub-population of mRNP particles more direct evidence of their possible mRNA components is still lacking.

This year's workshop was the first since the death of the founder, Wilhelm Bernard. His unforgettable qualities were recalled by Francoise Hagenau (University of Paris) who reminded us of his deep interest in the humanities and philosophy and his particular admiration of Goethe, who had lived at Weimar. At the workshops he sought always to unite different scientific specialities and different people and nations to make every worthwhile contribution part of an amicable synthesis. □

A deep-sea hydrothermal site on a strike-slip fault

Peter Lonsdale

University of California, San Diego, Marine Physical Laboratory of the Scripps Institution of Oceanography, La Jolla, California 92093

Submersible exploration of a young scarp in the San Clemente fault zone, at 1,800 m in the California Borderland, discovered tall piles of hydrothermal barite and dense colonies of large benthic animals. Phenomena along this active strike-slip fault zone resemble those at hot springs along the axes of mid-ocean ridges.

DIVE 355 of the US Navy submersible DSV-4 Seacliff, a half-sister of DSRV Alvin[1], landed at 1,805 m on the sandy suprafan of the Navy deep-sea fan[2], 70 km south-west of San Diego, California, in the South San Clemente Basin. The original intent of the dive was the geological examination of large-scale scour marks that have been cut by turbidity currents and mapped by a deep tow instrument[3]. Navigation was by echo-ranging to the Loran C-positioned mother ship, and by piloting on the deep tow chart. After travelling east across the hummocky fan surface for 1 km, the submersible obliquely ascended the 50–75 m scarp of a south-east trending fault (Fig. 1). The scarp has a clearly defined foot lapped by fan turbidites, and an abrupt crest at the top of a 60° slope. Although acoustic profiles (Fig. 2) indicate that the scarp truncates back-tilted beds of layered sediment, no semi-lithified outcrops were visible; the scarp surface is covered by silty mud, with signs of local mass-movement of unconsolidated sediment down its steepest segments. Both on the fan surface and on this part of the scarp the type and abundance of animal life seemed normal for basins in the California Borderland, with mobile holothurians, ophiuroids and quill worms the most obvious megafauna.

After climbing to the crest of the narrow fault ridge, Seacliff turned south and recrossed the scarp. At a position of 32°13.6′ N, 117°43.5′ W, about 500 m south-west of the first crossing, the foot of the scarp is marked by an uneven line of cones, columns and irregular piles of mineral deposits (Fig. 3*a*, *b*). They generally rise 2–3 m above the sediment surface, but one large mass has an estimated height of 10 m. Some of the deposits are white, and have a very uneven surface with many fingers and protuberances, but many of the larger masses have a smoother dark brown surface and a patchy dusting of sediment. The dark crust was easily broken by the submersible's manipulators, to reveal friable white interiors. Higher up the scarp, extending about half-way to the crest, are smaller white deposits, commonly seen as irregular fingers less than 1 m long projecting through the mud (Fig. 3*c*, *d*). Around some of these deposits the buff-coloured sediment bears thin patches of dark-brown soot-like material, the water within a few centimetres of white surfaces has a milky appearance, and there are dense colonies of large tube worms and other animals.

The mineral masses proved to be made of barite crystals. Although we lack direct evidence of anomalous bottom water, having had no water sensors or samplers on Seacliff, the phenomena at this site are interpreted as effects of mineralised thermal springs discharging along the fault line.

After almost an hour of photography (with hand-held 35 mm cameras through the observer's port) and sampling, the dive was curtailed because of mechanical difficulties. How far the baritic sinter and tube-worm clusters extend along the fault line was not determined, but it is at least 100 m.

Regional setting

The scarp at Navy Fan has been created by a component of dip-slip motion along the predominantly strike-slip San Clemente fault zone. Local vertical displacements are common along California strike-slip faults, with the uplift alternating from one side to the other along the fault trace; 100 km north-west of our study area tilted San Clemente Island has been formed by relative uplift of the opposite side of the fault. The fault ridge we examined preceded and steered the post-22,000 yr BP growth of Navy Fan[2], but continued motion on the fault line may be indicated by low scarps and lineations mapped by side-scan sonar on the fan surface north-west of the ridge[3]. We lack seismic profiles across the dive site, but the basement comes within 100 m of the sea floor at a crossing of the fault 5 km to the south-east[4]. The nearest sampled basement outcrop is at Navy Bank, where andesites have been dredged[5]; the basaltic andesites of San Clemente Island have been dated at 15–16 × 10^6 yr BP[6].

The San Clemente fault zone is but one of the several simultaneously active shear zones that make up southern California's broad strike-slip 'boundary' between the Pacific and American plates. It was once thought to connect with the Agua Blanca fault zone[3], but recent seismic reflection surveys[7] indicate that the principal fault trace is well offshore at Punta Banda, and continues south-south-west along the margin of Baja California (Fig. 1). The Miocene lavas of San Clemente Island are manifestations of widespread basaltic volcanism that was associated with plate-boundary tectonism in mid-Miocene to Pliocene times. The tholeiites, alkali basalts and basaltic andesites throughout this province are notable for their unusually high contents of barium[8,9]: for example, tholeiitic and transitional basalts from the Jacumba volcanics have up to 0.3% barium, more than 200 times the average for mid-ocean ridge tholeiites[8].

Quaternary igneous activity has probably been restricted to the Salton Trough, where incipient seafloor spreading may be taking place[10], but the geothermal gradient remains above average in much of the region[11]. There are many subaerial thermal springs with temperatures of 30–60 °C, concentrated

0028–0836/79/420531—04$01.00

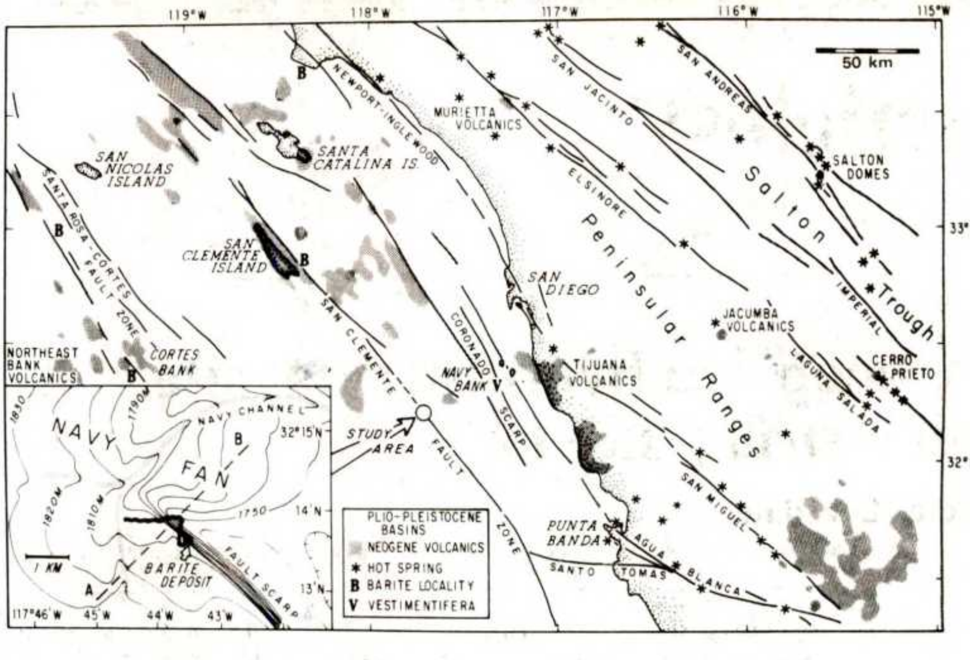

Fig. 1 Location map, showing principal Quaternary faults (after refs 5, 7, 33 and 34), offshore barite occurrences and the Vestimentifera type-locality[18]. Inset, with bathymetry from a deep tow survey[3] shows submersible track (solid line) and the position (A–B) of the 3.5-kHz profile of Fig. 2.

along the strike-slip shear zones (Fig. 1) where shattered bedrock and faulted alluvial cover are more permeable and frictional shear heating might be a significant local heat source[12]. Many of these springs deposit travertine. Where the Agua Blanca fault zone crosses the coast at Punta Banda, chemically-modified seawater flows from littoral thermal springs at temperatures of over 100 °C, and precipitates pyrite and gypsum[13]. Along the east coast of the Baja California peninsula some littoral springs deposit barium sulphate as well as calcium sulphate, most notably at Puertecitos (30°20′ N, 114°38′ W) where barite and pyrite forms extensive deposits around a thermal discharge from faulted Miocene and Pliocene volcanic rocks[14].

There have been no reports of active thermal springs in the Borderland, comparable to those in the same structural setting on land, but, of course, the problems of locating them in the deep sea are much greater. For many years it has been known that barite nodules occur within the mud at some of the Borderland's fault zones, and Revelle and Emery[15] interpreted samples from the San Clemente Island fault scarp as hydrothermal precipitates, formed when hot mineralised chloride solutions encountered sulphate-rich interstitial brines. Other suggestions for their genesis have included precipitation in evaporite basins[16,17]. More recently, porous masses of barite crystals, similar to those recovered by Seacliff Dive 355, have been dredged beside Cortes Bank in the Santa Rosa–Cortes fault zone[5] and on the Patton Escarpment (J. W. Hawkins, personal communication). We interpret these fragile crystalline masses as primary baritic sinters precipitated around thermal springs (hydrothermal vents) on the seabed. The nodules probably contain recemented barite reworked from older deposits of similar origin; the locality dredged by Revelle and Emery was reexamined and resampled in July 1979 on Alvin Dive 944, but no signs of recent hydrothermal activity were seen.

Sample description

Seacliff recovered 5 kg of barite from two separate piles. They are porous, open meshworks of small (10–100 μm) tabular crystals, and have a low saturated bulk density (1.6–1.8 g cm^{-3}) despite barite's high specific gravity (4.5). The barite crystals have a pearly lustre, and are grouped in a variety of dendritic and fan-shaped arrangements (Fig. 4). The crystal masses are contaminated by mud-filled burrows where worms have penetrated the friable material, but are otherwise very pure. No other mineral phases could be identified by X-ray diffraction. Chemical scanning for elements other than barium and sulphur, using an X-ray energy dispersive attachment to a scanning electron microscope, discovered significant amounts (>1% in some patches) of only iron and aluminum. Energy-dispersive X-ray spectrometry revealed only 0.2% strontium. Iron is probably present as fine-grained hydroxides, as some parts of the crystal masses have a light orange stain. One sample has a dark chocolate crust 1 mm thick. It is made of manganese oxide, contaminated with detrital silicate minerals but with a low iron

content. Despite its thinness, this crust helps hold the loose mass of barite crystals together, and must increase the resistance and persistence of the tall barite cones.

Benthic fauna

The most prominent animal life on the barite deposits and the intervening sediment slopes are dense tangles of tube worms. Many of the colonies near the large, brown-crusted deposits at the foot of the scarp may be dead: their crooked tubes are dusted with sediment and thickly festooned with epizoa, and no bodies were seen protruding from the tubes (though they could have been retracted inside). Near the fresher white deposits higher on the slope (for example, Fig. 3*b*, *c*) the tubes (many of them more than 1 m long and averaging 1 cm in diameter) tend to be straighter and less encumbered with epizoa, and several had dark red 'plumes' protruding from their tips. The animals were sampled, but their soft parts were not preserved; from their tubes and growth habit they are identified as the vestimentiferan *Lamellibrachia barhami*. Descriptions of this gutless annelid (?)[18,19] rely on specimens observed and collected by submersible at 1,125 m on the foot of Coronado Scarp, a fault scarp on the east side of San Diego Trough about 40 km from the Navy Fan site. Its only known close relatives are the Vestimentifera clustered around some thermal springs on mid-ocean ridges[20].

Unidentified bluish-grey organisms form apparently gelatinous masses draped over some barite surfaces and many of the chitinous tubes of the Vestimentiferae we photographed. Some of the sampled tubes had Bryozoa colonies. Large stalkless crinoids were attached to the tops of several barite cones (see Fig. 3*b*). Carpeting the sediment surface near some irregular white projections of barite were clusters of gastropods 4–5 cm long (Fig. 3*c*) and the valves of bivalve molluscs up to 10 cm long (Fig. 3*d*). Other animals seen around the barite deposits, but with an abundance not noticeably greater than elsewhere on the fan, include ophiuroids, holothurians, several types of fish and a large blue octopod (nestling in a barite concretion).

Interpretation and implications

The sinter-like deposits of barite on the floor of a Borderland basin are precipitates from mineralised springs along an offshore part of California's strike-slip fault system. Their evident capacity for carrying large amounts of barium in solution indicates that the springs were discharges of reduced hydrothermal fluid. Recent precipitation is attested by the fragility of the deposits and the absence on many surfaces of any coating of manganese oxide or sediment. The best signs of continuing active hydrothermal discharge, in the absence of direct temperature measurements, are the abundance of animals whose feeding habits attract them to thermal springs, and the milky appearance of bottom water in contact with some barite piles, reminiscent of the hydrothermal plumes at mid-ocean spreading centres[20]. By extrapolation, other places in the Borderland with nodular or massive barite are inferred to be sites of past or present thermal springs, as is the type-locality for *Lamellibrachia barhami* on the Coronado Scarp.

Several features of the continental margin site explored by Seacliff are comparable to the more spectacular deposits of oxides, silicates and sulphides and the dense clusters of large organisms found around thermal springs at axial fissures and strike-slip faults on mid-ocean ridges[20-24]. Seawater-based hydrothermal fluids that have reacted with young oceanic tholeiites at the Galapagos spreading centre[20] have the high barium enrichments predicted from laboratory studies[25], but no local accumulations of barite have been described. Barite precipitation has been reported from an actively spreading marginal basin[26], while dispersed barite crystals of probable hydrothermal origin are found over a large area of the East Pacific Rise[27], and in the Red Sea's metalliferous muds[28], where calcium sulphate is much more abundant.

The environment of thermal springs along the San Clemente fault one is different from those at accreting plate boundaries in that the geothermal gradient is much lower and the deep convective circulation must be much weaker. However, an active hydrothermal system has already been inferred for the San Clemente fault zone[29] from the pattern of conductive heat flow, which includes measured fluxes as high as 3.2 μcal cm^{-2}. The rocks and sediment available for reacting with hot, reduced seawater are also different from the sediment-free oceanic tholeiite of most mid-ocean ridges. Dominance of barite precipitation is attributable to the high concentration of barium in the local Neogene volcanic rocks.

In the convective circulation proposed for the San Clemente fault zone, seawater that penetrates shattered bedrock would have its sulphate reduced by reaction with volcanic rock, from which barium would be stripped by the chloride solution. A

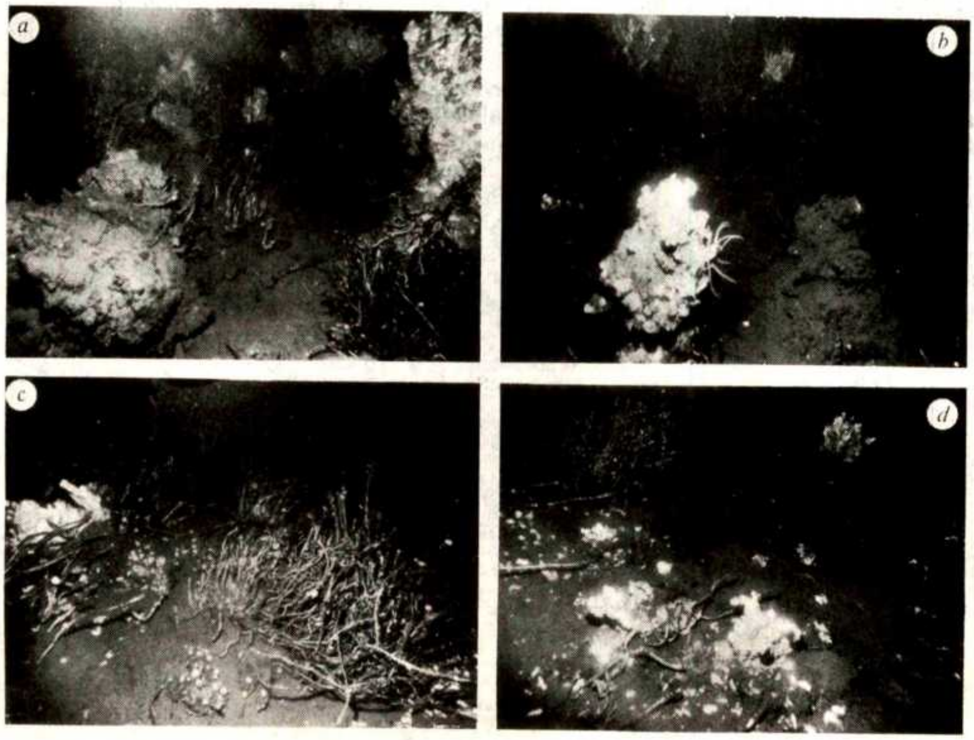

Fig. 3 Reproductions of colour photographs of the barite deposit, taken with a hand-held 35 mm camera through Seacliff's observation port. Field of view is about 3 m wide in mid-field. *a*, Irregular barite mounds 1–2 m high at the foot of the fault scarp, with tangled tubes of probably dead Vestimentiferae. *b*, Contrasting appearance of two barite mounds, one white and irregular (with a large stalkless crinoid), and one darker, smoother and veneered with sediment. *c*, the 30° lower slope of the fault scarp, with protruding 50 cm high 'fingers' of white barite, abundant tube worms (some definitely alive, with protruding red bodies), and clusters of white gastropods (on the sediment, barite, and some Vestimentifera tubes). *d*, Irregular clumps of barite, surrounded by milky water (poorly seen in this black and white reproduction), clusters of empty clam shells, and living Vestimentiferae. Irregular patches of dark, sooty sediment visible on the slope.

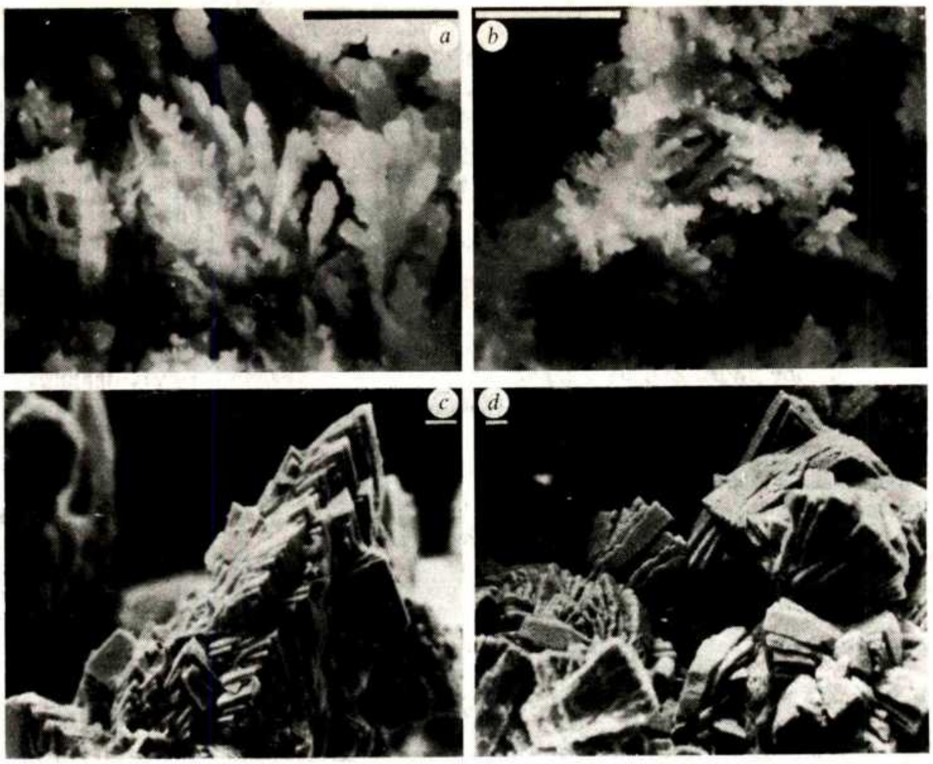

Fig. 4 Internal structure of barite crystal masses, as seen by a reflected light microscope (*a*, *b*; scale bar, 1 mm) and scanning electron microscope (*c*, *d*; scale bar 10 μm); platy crystals form spires and frondose structures projecting into internal cavities.

conduit for discharge through the relatively impermeable sediments is provided by the fault, which probably resembles strike-slip faults on land in being a belt of shearing 100–200 m wide, overlying a similar width of crushed bedrock. Precipitation of barite, which is undersaturated in normal seawater, would occur where barium-rich hydrothermal fluids mix with sulphate-rich bottom water. The large number of separate mounds of barite indicates a more diffuse discharge than occurs at ridge–crest hot springs, where there is no sediment cover to fractured bedrock. Because the crystal masses are so porous the precipitated mounds do not impede the discharge and seal the system. Those mounds with fresh white exteriors are believed to be slowly leaking barium-rich water, and growing barite crystals on their surfaces; their dynamics may be similar to the slow discharge through the porous deposits of manganese, iron and silica at the Galapagos Mounds Hydrothermal Field[20,30]. Manganese oxide precipitation on the mounds apparently occurs after outflow of barite-precipitating fluid has ceased, and does effectively decrease surface permeability and seal the discharge.

Iron and aluminum in the barite deposits has probably also been leached from underlying igneous rocks[15], which are also the most likely source of encrusting manganese. The dark sooty sediment nearby may be a loose precipitate of manganese oxide. Elsewhere, baritic sinters are often associated with sulphide ores of more valuable metals. In northeastern Honshu, barite occurs as onshore hot spring deposits, offshore nodules, and as the capping of Kuroko ore bodies–stratiform deposits of copper–lead–zinc sulphides formed at bathyal depths by Miocene hydrothermal precipitation in offshore basins overlying rhyolite and andesite[31,32]. Just as hydrothermal vents on the East Pacific Rise may now be producing mineral deposits similar to the Troodos-type massive sulphides[22], so thermal springs in the basins of the California Borderland may be modern ore-depositing counterparts of the Kuroko hot springs. The subaerial hot springs of Baja California have previously been suggested as the loci for active accumulation, at depth, of sulphide ores[33]; the prospective value of seawater-based hydrothermal systems like those in the Borderland is greater because of their enhanced ability to transport metals in chloride complexes. Establishing the abundance of mineralised thermal springs in the Borderland will require high-resolution observations along the fault zones there; in the submarine environment they are unlikely to be as far apart as the 10–50 km that separates fault-zone thermal springs on the adjacent semi-arid land (Fig. 1).

I thank all involved at US Navy Submarine Development Group One, operators of DSV Seacliff, especially P. Elliott, G. Goodwin, and B. Long. The profile of Fig. 2 was collected by H. Craig and F. Dixon. Partial semi-quantitative chemical analyses were provided by J. Bischoff. The work was partially funded by the Office of Naval Research, contract N00014-75-C-0704.

Modification of the oxygen-isotope record in deep-sea cores by Pleistocene dissolution cycles

Jonathan Erez*
Woods Hole Oceanographic Institution, Woods Hole, Massachusetts 02543

The glacial–interglacial amplitude (GIA) of oxygen-isotope curves in sediment cores from the Atlantic Ocean is much higher than the amplitude in the Pacific. This difference is explained by nonsynchronous $CaCO_3$ dissolution cycles during the Upper Pleistocene that amplify the GIA in the Atlantic and reduce the GIA in the Pacific. Efforts to assess palaeotemperatures in the Pleistocene using the stable isotope technique must consider the effects of dissolution.

MUCH of our knowledge on the Pleistocene epoch and its glaciations comes from oxygen isotope studies of foraminiferal skeletons from deep-sea cores. In addition to being a powerful stratigraphic tool[1–4], the oxygen isotope record provides information on the timing of glacials, sea-level fluctuations, palaeotemperatures, palaeosalinities and ice accumulation and melting during glacials and interglacials[1–9]. Deep-sea cores also display cyclic variation in $CaCO_3$ content. These $CaCO_3$ cycles have a periodicity similar to that of the Upper Pleistocene glacial–interglacial fluctuations and are probably caused by $CaCO_3$ dissolution[10–13]. The purpose of this article is to show how $CaCO_3$ dissolution cycles have modified the oxygen isotope record in deep-sea cores.

$CaCO_3$ dissolution cycles during the Pleistocene

The mechanism that causes $CaCO_3$ cycles in deep-sea cores is the subject of much debate and one reason for this is the lack of synchroneity between the Atlantic and the Pacific with respect to the timing of these cycles. In the Atlantic $CaCO_3$ content is high during interglacials and low during glacials, while in the Pacific the opposite is observed[10–16]. Variation in the $CaCO_3$ content of oceanic sediments can be caused by changes in $CaCO_3$ productivity, $CaCO_3$ dissolution and dilution by non-carbonate material. All these mechanisms and some of their combinations have been suggested to explain the $CaCO_3$ cycles and to account for the difference in timing between the Atlantic and the Pacific[10–16].

Broecker[14] and Berger[11] have convincingly shown that in the Pacific $CaCO_3$ cycles are caused mainly by dissolution. Their conclusions are based on $CaCO_3$ mass balance and on micropalaeontological criteria. Luz and Shackleton[12] provided additional evidence for $CaCO_3$ cycles in the Pacific being caused by dissolution, and also showed that these cycles lag a few thousand years behind the onset of glacials and interglacials. However, several authors suggested that $CaCO_3$ cycles in the Atlantic are not caused by dissolution, but rather by changes in $CaCO_3$ productivity or dilution with non-carbonate material[12,14,17,18]. More recent work in the Atlantic, especially by CLIMAP[19], has shown clearly that $CaCO_3$ cycles in the Atlantic are caused mainly by dissolution. The evidence for this is summarised briefly below.

Gardner[13] showed that in the eastern equatorial Atlantic, cores from relatively shallow water (~3,000 m) have high $CaCO_3$ content (~80%) and that glacial–interglacial carbonate variations are small. However, with increasing water depth average $CaCO_3$ content decreases and glacial–interglacial amplitudes increase (Figs 3 and 4 in ref. 13). This systematic variation with depth cannot be attributed to changes in productivity because these cores are located close to each other. Carbonate dissolution is strongly controlled by depth (mostly because of pressure increase) and thus can better explain this variation. Gardner[13] has also shown by material balance considerations that dilution alone cannot be responsible for the variation in $CaCO_3$ observed in this region. Following Gardner's calculation[13], it has been shown that at least 60% of the $CaCO_3$ deposited during glacials in the eastern equatorial Atlantic must have dissolved[20]. In addition, Gardner[13] found that benthonic/planktonic foraminifera ratio and shell fragmentation indicate increased dissolution during the low carbonate glacial stages. Bé *et al.*[21] showed a similar pattern in the western equatorial Atlantic. Glacial stages have low carbonate content, decreased coarse fraction, excessive fragmentation of planktonic foraminifera, absence of pteropods and increased benthonic/planktonic foraminifera ratio. Johnson *et al.*[16], Prell and Hays[22] and Thunell[23] found similar dissolution cycles in the southwestern Atlantic, Columbia Basin and the Gulf of Mexico, respectively. Therefore, although productivity changes and

Table 1 Comparison between the oxygen isotope composition of planktonic foraminifera from the uppermost sediment of two box cores in the North Atlantic Ocean, collected at 4,950 m and 4,500 m

Species	OC28-396 $\delta^{18}O$ (4,950 m)	OC28-395 $\delta^{18}O$ (4,500 m)	$\Delta\delta^{18}O$ (4,950–4,500 m)
G. ruber	−0.43	−0.71	+0.28
G. truncatulinoides	+0.98	+0.55	+0.43
G. inflata	+1.01	+0.74	+0.27
G. hirsuta	+1.23	+0.89	+0.34
G. conglobatus	+0.13	−0.20	+0.33
G. sacculifer	−0.55	−0.78	+0.23
G. siphonifera	+0.15	−0.06	+0.21
O. universa	−0.15	−0.20	+0.05
P. obliquiloculata	−0.12	+0.06	−0.18

Note that for all species except *P. obliquiloculata* $\delta^{18}O$ is higher in the deeper box core than in the shallow one. The difference in the isotopic composition is attributed to preferential dissolution of foraminifera that are isotopically lighter.

0028–0836/79/420535—04$01.00

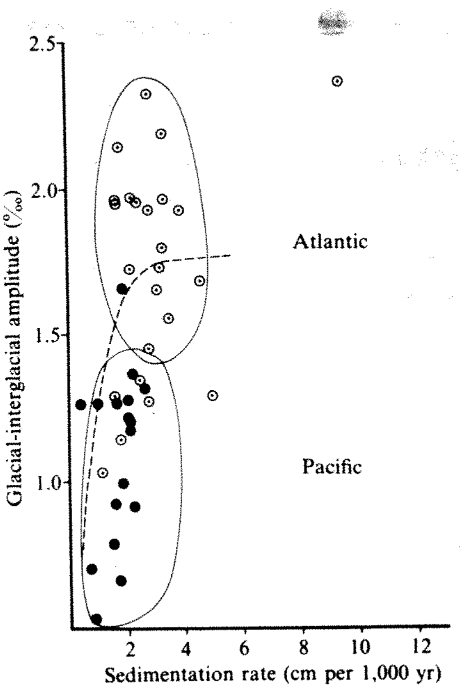

Fig. 1 The glacial–interglacial amplitude (GIA) of oxygen isotope curves in tests of planktonic foraminifera from sediment cores in the Atlantic (⊙) and Pacific (●) Oceans plotted against sedimentation rates in these cores. The isotopic composition is expressed in delta notation,

$$\delta^{18}O = \frac{(^{18}O/^{16}O)\ \text{sample}}{(^{18}O/^{16}O)\ \text{standard}} - 1 \times 1{,}000$$

Sources for the data and calculation of the amplitudes are discussed in Table 2. Note that the amplitudes in the Atlantic are significantly higher than amplitudes in the Pacific. The dashed line is the predicted GIA of a model suggested by Peng *et al.*[57] which accounts for bioturbation at different sedimentation rates. Most Atlantic amplitudes are higher, and Pacific amplitudes lower than the model predicts. The difference in the GIA between the two oceans is attributed to the effects of $CaCO_3$ dissolution cycles on the isotopic record.

dilution with non-carbonate material influenced carbonate content in certain areas, it seems that $CaCO_3$ cycles in both oceans are caused mainly by dissolution; they have similar frequencies as the glacials and interglacials; and the Atlantic and the Pacific are out of phase with respect to the timing of dissolution.

Today's oceans seem to be in agreement with the scheme suggested above. In the present interglacial the Atlantic is in a preservation mode, the CCD is roughly at 5–6 km and the saturation level ($\Omega = 1$) is at 4 km (ref. 24). The Pacific, on the other hand, is in a dissolution mode, its CCD is at 3–4 km and the saturation level ($\Omega = 1$) is at 1–2 km (ref. 24).

Effects of dissolution on the isotopic composition of planktonic foraminifera

Several authors have reported that Recent planktonic foraminifera recovered from the deep-ocean floor are isotopically heavier than their counterparts, recovered from shallower depths[25-27]. It was suggested that this enrichment in ^{18}O is caused by selective dissolution[25-28]. I have compared the isotopic composition of planktonic foraminifera recovered from the uppermost sediment of two box-cores from the north Atlantic (core OC28, 396 from 34°18′ N, 57°12′ W, in 4950 m water depth and core OC28, 395 from 33°43′ N, 57°27′ W in 4,500 m water depth). The results, shown in Table 1, are in good agreement with earlier studies mentioned above[25-27]. All species from the deeper box core with the exception of *Pulleniatina obliquiloculata* showed small but significant increase in $\delta^{18}O$ compared with the shallower box core. Visual observation of the foraminifera in these box cores indeed indicates that the specimens from 4,500 m are better preserved than those from 4,950 m, suggesting that dissolution is the prime cause for the difference in the isotopic composition between these two samples[20].

Planktonic foraminiferal tests collected in plankton tows are thin and fragile[28]. Their oxygen isotope composition is light (that is enriched in ^{16}O) and often in slight negative deviation from equilibrium[29-31], possibly caused by incorporation of isotopically light metabolic CO_2 which is enhanced by their symbiotic algae[20,32]. As foraminifera sink through the water column, part of the population continues to calcify, more chambers are added and the tests become thicker[20,33-37]. The isotopic composition of this part of the population is heavier because its skeleton is deposited in colder water and the activity of symbiotic algae ceases below the photic zone[20,30,38]. Dissolution of the overall population tends to first remove the light-weight fragile individuals which are isotopically lighter[28]. Consequently, the surviving population is isotopically heavier. This scheme which has recently been confirmed by comparison of planktonic foraminifera from plankton tows, sediment traps and sediments[20], explains how dissolution makes the isotopic composition of a species population heavier. It is now possible to examine the effect of $CaCO_3$ dissolution cycles on the isotopic record of the Pleistocene.

Effects of dissolution cycles on the isotopic record of the Pleistocene

When considering this problem, absolute values of $\delta^{18}O$ are of little interest because large variability exists between and within species due to their depth and geographic distribution. It should also be remembered that intercalibration between laboratories is not complete, especially because different treatments are used to remove the organic contaminants before isotopic analysis. For these reasons, I will consider here only the effects of dissolution on the isotopic glacial interglacial amplitude (GIA) which is comparable between species and between laboratories.

Most authors agree that the major factor controlling the GIA is ice volume in the Northern Hemisphere and its isotopic composition[1-3,39-41]. Temperature, assumed to be the main factor by Emiliani[5,6], seems to be of secondary importance (see more recent reviews by Hecht[42], Van Donk[43], and Shackleton[4]). Remarkable similarity exists in the shape and frequency content of $\delta^{18}O$ curves in the Atlantic and the Pacific Oceans. However, there is a large difference in the GIA between the two oceans[1,5,6,41]. Figure 1 and Table 2 summarise most of the pertinent data on the GIA exhibited by planktonic foraminifera. Most Atlantic cores show an amplitude of ~1.9‰, whereas most Pacific cores show an amplitude of ~1.1‰. Emiliani[5,6,44], Imbrie *et al.*[40], Shackleton and Opdyke[2,3], and Berger and Gardner[41], who tried to explain this difference, assumed that the Pacific responded only to the ice volume effect whereas in the Atlantic additional effects of temperature and evaporation/precipitation are superimposed on the ice-volume effect.

I suggest that most of the difference observed in the GIA between the Atlantic and the Pacific is caused by $CaCO_3$ dissolution cycles. Dissolution effects on the isotopic composition of a species population are quite small, perhaps in the range 0.2–0.4‰ (Table 1 and refs 25, 27). However, the timing of dissolution–preservation cycles within and between the two oceans can amplify the effects of dissolution on the GIA. Foraminifera in a well preserved core (even above the foraminiferal lysocline) are already partially dissolved[45], so the isotopic composition of such foraminifera is somewhat heavier than the original composition. Additional dissolution will make the isotopic composition even heavier, while better preservation will make the isotopic composition lighter and closer to the original.

In the Atlantic relatively heavy isotopic composition during glacials will become even heavier due to increased dissolution, and light isotopic composition during interglacials will become lighter because of preservation. Thus the total effect is an

Data were selected from refs 2–6 and 40. Cores that did not have adequate sampling density or did not show the regular glacial–interglacial pattern were omitted. The amplitude was calculated by the difference between the highest and lowest $\delta^{18}O$ value in the uppermost section of each core, which represents the last glacial and the present interglacial. Sedimentation rate was calculated for the same core section assuming an age of 18,000 ys ago to the peak of the last glacial. Note that the GIA in the Atlantic is almost doubled compared to the Pacific.

* EA, Equatorial Atlantic; EP, Equatorial Pacific; NA, North Atlantic; NP, North Pacific; SA, South Atlantic; SP, South Pacific; CR, Caribbean.

increase in GIA (Fig. 2). In the Pacific the light isotopic composition during interglacials will become slightly heavier due to dissolution while the heavy isotopic composition during glacials will become lighter due to preservation. This will reduce the GIA in the Pacific (Fig. 2). If we assume that dissolution or preservation shifts the isotopic composition only by 0.2‰, the GIA in the Pacific may be reduced by 0.4‰, and amplified in the Atlantic by 0.4‰, thus the difference in the GIA between the two oceans may reach 0.8‰ which is quite close to the observed values (Table 2, Fig. 1).

The following studies by other investigators support my interpretation. Berger and Gardner[41] have suggested that dissolution caused the extremely low GIA in the Pacific (0.2–0.8‰) reported by Emiliani[5]. Shackleton and Opdyke[3] have also shown that within the Pacific, core V28-238 from 3,120 m recorded a larger GIA than core V28-239 from 3,450 m. The average difference in GIA between the two cores was 0.29‰. Shackleton and Opdyke[2] showed that the GIA recorded by benthonic foraminifera in core V28-238 is higher by 0.2‰ than that recorded by *Globigerinoides sacculifer*. They suggested that *G. sacculifer* migrated downwards during the interglacial to account for this observation. While this is not impossible, it is easier to explain this difference by dissolution that reduced the GIA recorded by *G. sacculifer*, but did not change the GIA recorded by benthonic foraminifera which are more dissolution resistant.

Berger and Killingley[27] have recently compared the isotopic record of the past 19,000 yr in two western equatorial Pacific box cores from 1,597 m and 3,732 m. They showed that the isotopic composition of *P. obliquiloculata* (a dissolution-resistant species) was unaffected by dissolution, while the isotopic composition of *G. sacculifer* (which is dissolution susceptible) was significantly heavier in the deeper box core due to dissolution during the past 10,000 yr. Thus the GIA recorded by *G. sacculifer* in the deeper core is lower by 0.3‰ than the GIA recorded by *P. obliquiloculata*.

In the Atlantic, it is expected that dissolution resistant species will show a smaller GIA than dissolution susceptible species. Indeed, in the Caribbean core A-179-4 (from 2,965 m), Emiliani[5] showed that while the dissolution susceptible species *G. ruber* and *G. sacculifer* had high GIA values of 2.05‰ and 1.94‰ respectively, the dissolution resistant species *G. dubia* (*dutertrei*) and *G. menardii* had GIA values of 1.37‰ and 0.75‰ respectively. This trend has been shown to persist through time by Lidz *et al.*[46] who found that *G. tumida*, *G. truncatulinoides* and *G. crassaformis* showed lower GIA values compared with dissolution susceptible species (*G. sacculifer*, *H. pelagica*, *O. universa* and *G. conglobatus*).

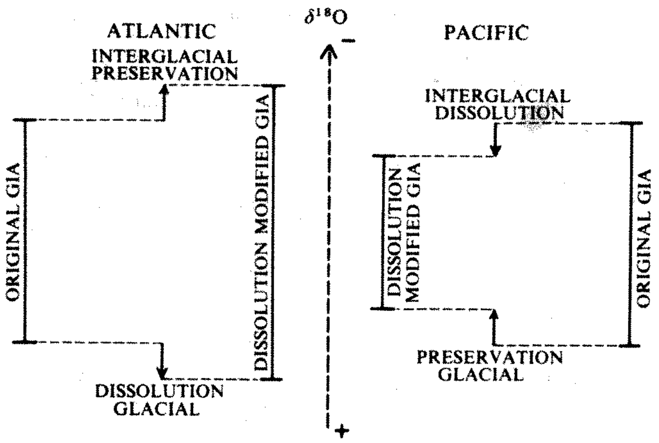

Fig. 2 Schematic presentation of modifications in the glacial–interglacial amplitude (GIA) of $\delta^{18}O$ curves caused by dissolution cycles in the Atlantic and the Pacific Oceans. The original GIA is that which would have been recorded in a well preserved core (above the lysocline) if dissolution–preservation cycles would not have existed. Note that $CaCO_3$ dissolution cycles amplify the GIA in the Atlantic while they reduce the GIA in the Pacific.

Discussion

The observations discussed above can be interpreted to show that processes other than dissolution were in operation. Emiliani[5,6,44], Shackleton and Opdyke[2], Lidz *et al.*[46], and Berger and Gardner[41], suggested that the higher GIA in the Atlantic is a result of significant temperature fluctuations between the glacials and interglacials. Vertical migration of planktonic foraminifera combined with temperature changes between glacials and interglacials can potentially account for the differences between benthonic and planktonic foraminifera as well as the differences between shallow and deep dwelling planktonics. Quantitative estimates of palaeotemperatures derived from microfossil distribution in deep sea cores support the idea that small glacial–interglacial temperature fluctuations indeed occurred in the Atlantic[44,47,48]. However, using the same quantitative techniques, other studies have shown that similar or even larger temperature fluctuations occurred in the Pacific[49]. Therefore, micropalaeontologically derived palaeotemperatures cannot explain the difference in the GIA between the two oceans.

Recently Shackleton[4] has shown that the GIA recorded by benthonic foraminifera is at least 1.65‰, and this value is believed to represent the change in $\delta^{18}O$ of ocean water due to ice accumulation and melting. In comparison, *G. sacculifer* in the Pacific shows an average GIA of 1.13‰ (based on 13 cores in Table 2). If this difference is interpreted in terms of temperature changes, it implies that *G. sacculifer* in the Pacific lived in warmer water during the glacial and colder water during the interglacial. While this is not impossible, it is more likely that the reduced GIA of *G. sacculifer* is caused by dissolution. If dissolution does reduce the GIA of planktonic foraminifera in the Pacific, it must also increase the GIA in the Atlantic. Indeed, *G. sacculifer* in the Atlantic shows an average GIA of 1.82‰ (based on 14 cores, Table 2). Therefore, there is no need to evoke cooling and warming of Atlantic surface water to explain the differences in the GIA between the two oceans.

Finally, effects of bioturbation on the isotopic record must be considered. It has been recognised since the pioneer work of Emiliani[5,6] that bioturbation can blur the isotopic record and thus reduce the GIA[4–6,50]. Because biogenic mixing affects only the upper few centimetres, cores with low accumulation rates are expected to show a lower GIA than those with high accumulation rates. Shackleton[4] showed that this is indeed the case in a few selected cores from the Atlantic and the Pacific. However, in these studies no differentiation was made between planktonic and benthonic foraminifera. Peng *et al.*[51] suggested a model to account for the effects of bioturbation on the GIA. Their model matches their data for benthonic foraminifera much better than it does for planktonic foraminifera (see Fig. 4 in ref. 51). Most of their data points for planktonic foraminifera are from the Pacific and they display a lower GIA than expected if bioturbation was the main factor in operation. Figure 1 shows the GIA versus sedimentation rate for all the data recently available for planktonic foraminifera (see also Table 2). In addition, the predicted GIA has been reproduced using the Peng *et al.*[51] model. It is clear that most Pacific data points fall below the predicted GIA and most Atlantic data points fall above the predicted GIA. Thus, although the effects of bioturbation are certainly important, dissolution certainly adds a significant modification to the isotopic record that cannot be ignored. Perhaps when techniques to 'unmix' the past record[51,52] are improved, better assessment of dissolution effects will be possible.

This study was supported by NSF grant 77-07732. I thank S. Honjo, N. Shackleton, J. Milliman and R. Thunell for their help and criticism.

Aminostratigraphy of UK Pleistocene deposits

Gifford H. Miller*, John T. Hollin & John T. Andrews*

Institute of Arctic and Alpine Research, University of Colorado, Boulder, Colorado 80309
* Department of Geological Sciences, University of Colorado, Boulder, Colorado 80309

Ratios of D-*alloisoleucine to* L-*isoleucine have been determined on freshwater molluscs from 13 interglacial sites in South East England and on marine molluscs and foraminifera from 10 Pleistocene and Upper Pliocene Crag sites in East Anglia. We can distinguish the Ipswichian, then either one or two interglacials that may be younger than the classical Hoxnian, then the Pleistocene Crags, then the Pliocene Coralline Crag.*

AMINO ACID reactions derived from protein degradation in molluscan fossils have received considerable attention as a means of correlating and dating Pleistocene deposits[1-5]. Although several reactions are potential chronological indices, in this study we have concentrated on the isoleucine epimerisation reaction. Over geological time, isoleucine, initially present in shell protein exclusively in the L configuration, epimerises to its non-protein diastereomer D-alloisoleucine. The proportion of the two acids, expressed as the allo/iso ratio, increases to an equilibrium value of 1.30±0.05. The rate of the epimerisation reaction is most sensitive to temperature; other potentially influential environmental parameters such as pH and leaching are effectively excluded by the integrity and natural buffering effects of the carbonate matrix. The activation energy for the isoleucine epimerisation reaction in carbonate fossils is ~ 29.0 kcal mol^{-1} (ref. 6). This corresponds to an approximate doubling of the apparent age for every 4 °C temperature rise in the range between 0 and 20 °C. Consequently, absolute age assessment requires a precise estimate of the integrated thermal history since shell deposition for each site and an accurate kinetic model. It is, however, possible to circumvent the thermal term by analysing samples from a limited geographic region over which the temperature fluctuations, while unknown, can be assumed to have affected the region uniformly. In such a region, amino acid ratios may be used directly as correlation and relative age indices (aminostratigraphy[7]). We favour this approach as it requires a minimum of assumptions and yields the least ambiguous results. Another potential source of error results from the non-linear relationship between reaction rate and temperature. Samples lying close to the surface for a substantial portion of their burial history may yield anomalously high ratios due to their greater seasonal and diurnal temperature ranges. We prefer to analyse samples collected from at least 1 m depth.

Interglacial sites and amino acid analyses

For our work on interglacial deposits from the Thames estuary and adjacent sites we chose the freshwater mollusc *Corbicula fluminalis*. This shell is abundant in many English interglacial sites[8]. It does not occur in England today, but the genus is widely distributed in the Old World and is currently invading the US[9]. Most of our sites were largely worked out in the last century, and most of our samples came from the collections in the British Museum (Natural History). We stress that the precise provenance of these samples is unknown. Without more historical research, the BMNH localities should be preceded by the words 'somewhere at'. However, this study was exploratory and for this purpose our samples have served very well.

From each site we have analysed three or more valves of *C. fluminalis* (when possible we select right values to avoid analysing the same individual twice). Amino acid residues in both the free and total (free plus peptide-bound) fractions are determined on an automated ion-exchange amino acid analyser[7]. Monospecific samples were chosen to avoid problems with the species dependency of racemisation rates.

Table 1 shows the isoleucine epimerisation ratios in the total amino acid fraction for all *Corbicula* analysed. A certain amount of scatter in the amino acid ratios is expected; Miller and Hare[9] suggest this should amount to less than 10–15% of the mean. The mean value is considered representative of the deposit for

Epimerisation was determined as the ratio of D-alloisoleucine to L-isoleucine in the total amino acid assemblage after conventional acid hydrolysis.

* We have noted a correlation between the ratio of aspartic acid to glutamic acid (Asp/Glu) and the isoleucine epimerisation ratio within shells of Group 2. *Corbicula* with low Asp/Glu values have high allo/iso ratios. In the Stutton collection analyses 708 D-H were made on different portions of a single valve. 708 D, the hinge area, yielded an allo/iso ratio substantially above the other portions (centre, central, anterior and posterior growing edges; E–H respectively). Similarly, the Asp/Glu ratio in 708 D is less than half the value of the other portions. The cause of such differences within a single valve is not readily apparent, but may be related to the calicification process. Weiner[37] has recently demonstrated a link between aspartic acid and calcium in mollusc shells. We have refrained from analysing the hinge area in other specimens to minimise the intravalve variation.

† *Corbicula* sp. from Russellville, Arkansas, provided by Dr L. R. Kraemer.

‡ Sample C from Aveley collected by Mr G. R. Ward of the Passmore Edwards Museum, from Hollin's (ref. 12) Unit 3. Samples A and B, from BMNH collections, are probably from the same unit.

§ Samples from BMNH collections, via Mr J. Cooper. The Stutton, Ilford, Shoeburyness, Grays, and probably the Clacton samples are from the Kennard collection, Selsey from the Davis collection, Hackney from the Evans collection and Stoke Newington from the Smith collection. The origin of the Clapton shells is uncertain.

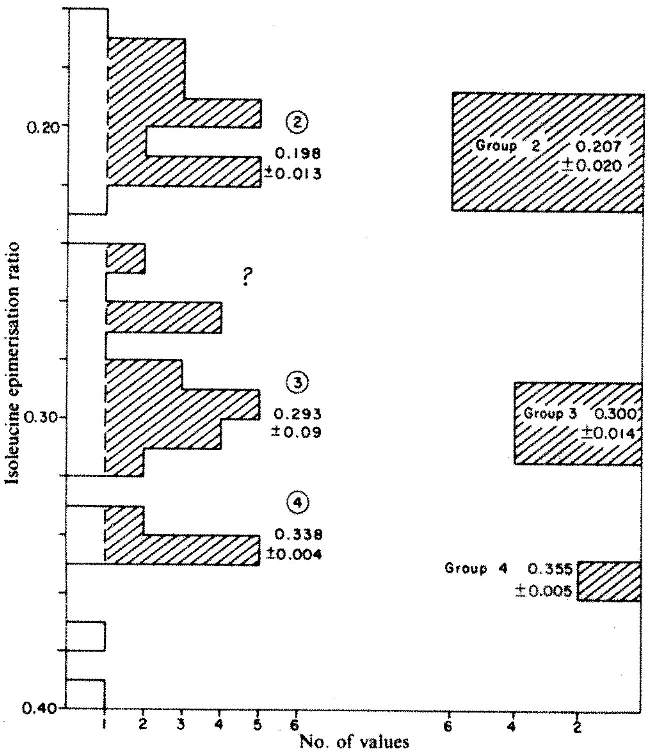

Fig. 2 Frequency distribution of individual isoleucine epimerisation (allo/iso) ratios in *Corbicula* from interglacial sites in SE England. Only ratios with more than one individual determination were considered significant in defining the three clusters on the left. Means and standard deviations from Groups 2–4 in Table 1 are on right for comparison.

collections with a standard deviation of 15% or less. Greater deviations mean that one or more determinations are suspect. As in most Quaternary fluvial and shallow marine deposits, some samples may be reworked[10]. Hence, it may be more realistic to consider only the lowest ratio when comparing sites (Table 1). However, whether we consider the mean, or the lowest allo/iso ratios, five distinct groups are apparent in Table 1, with the only overlap being at Selsey and Hackney.

There is another, independent technique of evaluating the amino acid data. We can start with the assumption that the stratigraphy of most sites is not sufficiently documented to demonstrate the contemporaneity of each valve with a specific stratum. Consequently we may simply have a collection of *Corbicula* from an unknown array of interglacial ages. In Fig. 2 we have plotted the distribution of individual allo/iso determinations between 0.15 and 0.40 (Groups 2, 3 and 4). The distribution is clearly non-random and three prominent clusters are apparent, with a possible additional cluster between allo/iso 0.24 and 0.26. The means and deviations for these clusters compare favourably with the means of Groups 2, 3 and 4 in Table 1 (see Fig. 2). Whether the allo/iso ratios are plotted by minimum or mean values for each collection, or simply as a composite of all values, five groups are clearly defined, with few ambiguous samples.

Amino acid groups and British Standard Stages

Group 1, a modern sample from Arkansas, is separated by a considerable interval from Group 2. Most of the Group 2 sites have been assigned by most workers to the last, Ipswichian, interglacial in the British Standard Stages[11]. Comprehensive references to the sites at Aveley, Sutton, Crayford and Ilford are given in ref. 12. The location of the *Corbicula* site at Shoeburyness is uncertain[13–15]. The pollen at Selsey is typically Ipswichian[16], and perhaps the higher ratios there represent a temperature effect on the shells, from either their southerly position or their shallow burial on the foreshore. However, note that Baden-Powell[17] assigned some marine shells in this area to his 'Tyrrhenian', last-but-one interglacial. The only anomalous result in Group 2 is from Clacton, which is generally assigned to the Hoxnian interglacial in the Standard Stages. Only a few *Corbicula* have been reported from Clacton[18]. The BMNH Kennard collection contains only a few valves, and we agreed to analyse one juvenile. Our result is so precisely Ipswichian that it is unlikely to represent a failure of our method. Either the collection is mixed, or perhaps the 3 km extent of the Clacton deposits[18,19] includes a patch of Ipswichian material. In another attempt to relate the amino acid ratios to a Hoxnian pollen site, Cooper was able to supply one *Macoma* sp. marine shell from Selsea Bill and two *Macoma* from Clacton. In this case the Clacton shells were clearly older. Note from the Selsey ratios in Tables 1 and 2 that *Macoma* racemises more rapidly than *Corbicula*.

Most of our Group 3 sites have been assigned at some time to a last-but-one interglacial. However, none of them has yielded a diagnostic pollen diagram, and their assignment to the Hoxnian Stage is far from certain. The Hackney, Clapton and Stoke Newington samples are presumably all from the Hackney

Table 2 Isoleucine epimerisation in molluscs from Crag deposits

Table 3 Isoleucine epimerisation in the foraminifera *Elphidiella hannai* from the Ludham Pilot Bore (Fig. 1)

Sample ID	Depth (m, O.D.)	Pollen zone	Foram. zone	Stage	Ratios
LP9	−11.7 to −13.1	L_p4b/4c	L_f6	Bav./Pre-Past.	0.79 0.81
LP17	−25.1 to −26.5	L_p1b/2	L_f3	Thur.-Lud. (early Norw. Crag)	0.81 0.83
LP20	−28.8 to −31.9	L_p1b	L_f2	Upper Lud. (earliest Norw. Crag)	0.90 1.06

Samples provided by B. M. Funnell, University of East Anglia, and prepared by A. R. Nelson, Dalhousie University. Each determination included several foraminifera tests. For a discussion of the stages here, see ref. 38.

London Borough sites exposed in the last century and reviewed by Wymer (ref. 20, p. 297–306). Hackney L. B. covers an area more than 3 km across, with elevations from 3 to above 30 m O.D., and it probably includes deposits of more than one age (ref. 20, pp. 317–319; ref. 27). The relatively low ratios from Hackney suggest the possibility of an interglacial stage or substage intermediate between Groups 2 and 3 in age, represented perhaps by the cluster of ratios between 0.24 and 0.26 in Fig. 2. The Grays shells are separated in the BMNH collections from those from West Thurrock, so are almost certainly from Little Thurrock[12]. Traditionally[18,20,21–23], the mammals at Little Thurrock have been assigned to a last-but-one interglacial, although West[24] and Hollin[12] thought that the polleniferous brickearth there was more likely to be Ipswichian than Hoxnian. The *Corbicula* from Little Thurrock must come from below 15 m O.D. (ref. 12). The *Corbicula* from our site at Dierden's Pit, just across the river at Swanscombe, are correlated by Kerney[25] with those reported from the Middle Gravels of the nearby Barnfield Pit, at about 27 m O.D. (ref. 20, pp. 332–354; ref. 26). *Corbicula* is notably absent from the underlying Lower Loam and Lower Gravel at Barnfield Pit[25], at an elevation intermediate between the Middle Gravels and Little Thurrock. This absence reinforces Hubbard's suggestion[27], that the Middle Gravels may be from a separate, younger interglacial than the Lower Loam and Lower Gravel. And the molluscs in the Lower Loam[25] and the archaeology from the Lower Gravel[20] resemble those at Clacton, where the pollen resembles that in the type site of the Hoxnian interglacial at Hoxne (Turner, in ref. 25).

Our Group 4 ratios come from the large interglacial site at Purfleet. Allen's[28] samples were collected 40 cm above the base of the laminated beds (Hollin's[12] Unit 2) in Greenlands north face. The ratios from the shelly channel (Unit 3) suggest that this is from the same interglacial. Hollin thought that the laminated beds were most probably Ipswichian, but very possibly older; and Allen thought that they might be from an interglacial between the Ipswichian and Hoxnian. The amino acid ratios suggest that they are at least as old as Dierden's Pit and the Middle Gravels at Swanscombe. This now fits in well with the conclusions of Palmer[29], that the archaeology from the overlying gravel and sand (Unit 4) at Purfleet resembles that in the Middle Gravels. Like that at Little Thurrock, the pollen in the laminated beds at Purfleet appears to be from the first half of an interglacial[12]. There is some overlap in the ratios at these two sites, so perhaps this is the Group 3 interglacial; it is unlikely to be the Hoxnian, since *Corbicula* is not recorded in the first half of the interglacial at Clacton[25]. And following the Clacton disappointment above, we have failed to locate any more *Corbicula* from a Hoxnian pollen site; the time relationship between our Groups 3 and 4 and the Hoxnian will have to be determined in some future campaign with some other species.

The Group 5 ratios come from the old pit at Hill Farm Wangford, in the Crag deposits, and provide a link with the marine, *Mya* sp. ratios below. Funnell and West (ref. 30, p. 253–254) discuss whether the 'Chillesford pollen assemblage' at Wangford is Pastonian (the interglacial before the Cromerian) or much older. Our results favour the latter.

Crag deposits of East Anglia

We report here on our efforts to stratify and correlate Crag deposits on the basis of the isoleucine epimerisation reaction in shells of the marine genera *Mya* and *Macoma* (Table 2). Our stratigraphic terminology follows Funnell and West[30]. We are able to link the Crag deposits to the interglacial units by comparing allo/iso ratios in *Corbicula* and *Mya* from Wangford (Tables 1 and 2; 0.76 and 0.89 respectively). The *Mya* values are somewhat above those in *Corbicula*, suggesting a more rapid epimerisation in the former. We have little faith in the *Macoma* results from the Crags, first because in this case we have no link with *Corbicula*, and second because most *Macoma* yielded anomalously low total amino acid concentrations.

Individual allo/iso ratios in *Mya* from the Crag deposits range from 0.89 to 1.25. This result indicates that epimerisation has not reached equilibrium for most sites, in spite of their age. The *Mya* ratios from the Crag units define only two broad groups; a younger one that includes the Red Crag Formation, Norwich Crag Formation and Weybourne Crag, and a second, older one

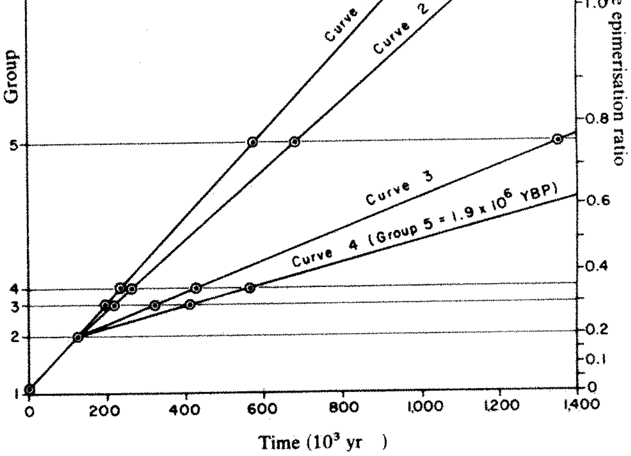

Fig. 3 Possible ages of Groups 3–5, assuming Group 2 is from 124,000 BP. Curve 1 assumes that reversible first order kinetics are followed exactly, Curve 2 that Group 3 is from 210,000 BP, Curve 3 that Group 3 is from 310,000 BP and Group 4 that Group 3 is from 410,000 BP.

consisting of the Coralline Crag. Shell fragments of *Mya* or *Arctica* collected from the Sudbourne Park Pit near Orford are from the lower shelly sands of the Coralline Crag. Allo/iso ratios are close to equilibrium, indicating that these Pliocene deposits are at the limit of the amino acid method for UK deposits. Within the younger group, average ratios range from 0.86 to 1.08. The Red Crag Formation is the oldest unit within this group and represents the basal deposits of the British Pleistocene succession. *Mya* from the Neutral Farm Pit of the Red Crag Formation have allo/iso ratios close to 1.0, significantly lower than those in the underlying Coralline Crag. Ratios in *Mya* from units within the Norwich Crag Formation range between 0.89 and 1.08, but are not always in correct stratigraphic order. Analyses of additional shell material should allow us to determine whether these discrepancies represent noise in the method or reflect reworking of shells from older units. The amino acid data suggest that the Weybourne Crag at West Runton is similar in age to the younger members of the Norwich Crag Formation.

Late in this study we were able to obtain foraminifera from the Ludham Pilot Bore in the Crag deposits. The epimerisation data (Table 3) are in the correct stratigraphic order and are similar to ratios in marine molluscs from correlative units.

Future work on the Crags of eastern England, especially if that work is concerned with the question of chrono-correlation, means analysing rather large numbers of samples. How large? If we wish to distinguish between the different Crag units, and if shells in these units differ in allo/iso ratios by 0.04, we can use our data to calculate that the number of runs required to discriminate between the units is equal to:

$$N = 4\sigma^2/L^2$$

where σ^2 is the variance of the population, and L is the limit we wish to apply (in our case, 0.04). If we set $\sigma^2 = \pm 0.1$ (a conservative figure) then we need 25 runs to be able to distinguish between two populations at the 95% confidence level. If $\sigma^2 = \pm 0.06$ then nine samples would be sufficient.

Discussion

The ratios above are generally in the correct chronostratigraphic order, and we discuss now how they may correlate with the worldwide marine oxygen isotope stratigraphy[31] and with an absolute time scale[32]. In Group 2, the presumably tidal[12,28] laminations at Crayford, the maritime herbs at Ilford, and the apparent level of the old floodplain at Aveley all suggest an early Ipswichian sea level of roughly 7 m (ref. 12: note that the possibility of the laminated beds at Little Thurrock and Purfleet being pre-Ipswichian was allowed for in that paper). In turn, this suggests a correlation with the worldwide high sea stand at 124,000 BP[33] and thereby with isotope Stage 5e[34]. A U-series date of 125,000 BP has been obtained on a bone from Stutton[35].

On the assumption that Group 2 (mean ratio 0.207) dates from 124,000 BP, we can make some estimate of the ages of the older groups. However, conversion of allo/iso ratios into absolute ages is not straightforward. The isoleucine epimerisation reaction does not follow first-order reversible kinetics in carbonate fossils. Shell amino acids, initially bound in high molecular weight peptide chains, are slowly released in the free state over geological time but are retained within the carbonate matrix. The epimerisation rate differs for free and bound isoleucine [relative reaction rates as follows: terminal (C or N) $\gg$ internal $\approx$ free][36]. Because the proportion of free isoleucine increases in older samples, there is a general reduction in the epimerisation rate with increasing sample age. First order kinetics may eventually be approximated, but at no point does the reaction rate increase. Hence, temporal extrapolations from younger (last interglacial) to older samples will yield minimum ages.

In Fig. 3, we have plotted the allo/iso ratios

$$\ln\left(\frac{1+\mathrm{D/L}}{1-0.77(\mathrm{D/L})}\right) \quad \text{against time}^6$$

Curve 1 assumes shells in Group 2 are 124,000 yr old and that the isoleucine epimerisation reaction in *Corbicula* follows first order reversible kinetics exactly. The age predicted for Group 3 (190,000 BP) is a little low for the pre-Ipswichian interglacial Stage 7 (ref. 32). If we fix the age of Group 3 at 210,000 BP (roughly the mid-point of Stage 7), the age of Group 5 becomes $\geq$680,000 BP (curve 2). Fixing Group 3 at 310,000 BP (roughly the mid-point of the next interglacial, Stage 9), yields a Group 5 age of $\geq 1.35 \times 10^6$ BP (curve 3). Fixing Group 3 at 410,000 BP (an early estimate for the age of Stage 11), yields a Group 5 age of 1.9×10^6 BP (curve 4), which seems improbably old for the Norwich Crag.

We conclude, therefore, that our Group 3 probably belongs to isotope Stage 7 or 9. Unfortunately, we do not feel that the available geological evidence allows us to choose between these possibilities as yet. If we assign Group 3 ratios to Stage 7, extrapolation from Table 2 and Fig. 3 suggests an age for the younger Crag group of 0.7 to 1.2×10^6 BP and for the Coralline Crag of 1.9×10^6 BP. If we assign Group 3 to Stage 9, these ages become 1.0 to 1.8×10^6 BP and $\sim 3.0 \times 10^6$ BP. Especially valuable now would be a UK Pleistocene section with a recognisable palaeomagnetic reversal bracketed by shells.

We thank all those, especially J. Cooper, P. Cambridge and B. M. Funnell, who helped in supplying and identifying samples. Dr N. J. Shackleton and Professor R. G. West made helpful suggestions. J.T.A. was assisted by a University of Colorado Faculty Fellowship to the University of East Anglia in 1977, and J. T. H. was assisted by a NOAA Senior Associateship through NRC in 1978. Support for the Amino Acid Geochronology Laboratory at the University of Colorado came from NSF grant EAR 77-24555.

DNA coding for human growth hormone was constructed by using chemically synthesised DNA in conjunction with enzymatically prepared cDNA. This 'hybrid' gene was expressed in Escherichia coli *under the control of the* lac *promoter. A polypeptide was produced having the size and immunological properties characteristic of mature human growth hormone.*

HUMAN GROWTH HORMONE (HGH) is a protein of 191 amino acids which is synthesised in the anterior lobe of the pituitary. Growth in hypopituitary dwarfs, whose small stature is due to a deficiency of HGH, can be restored during childhood by administration of this hormone[1]. In addition, HGH may prove effective in the treatment of a variety of ailments, including bone fractures, skin burns and bleeding ulcers[2]. As growth hormone is species specific, human cadavers have been the only source of HGH.

The primary translation product of growth hormone mRNA is a precursor protein consisting of a signal peptide attached to the N-terminus of growth hormone[3]. Such signal or 'pre' sequences are characteristic of secreted proteins. In the case of rat growth hormone (RGH), DNA sequencing of cDNA prepared from RGH mRNA has identified the 26 amino acid residues of the pre-sequence[4]. From information derived from the cDNA sequence of human growth hormone[5] we have designed and constructed a bacterial plasmid which instructs the synthesis of substantial quantities of mature HGH in a microbial cell.

HGH gene assembly strategy

The general approach used for the bacterial synthesis of HGH involves a combination of the cloning of the complementary DNA (cDNA) prepared from pituitary mRNA with the cloning of chemically synthesised DNA. The specific strategy was based on the known restriction endonuclease pattern of HGH cDNA[5]. *Hae*III sites are present in the 3′ noncoding region and in the sequence coding for amino acids 23 and 24 of HGH. Treatment of double stranded (ds) HGH cDNA with *Hae*III gives a DNA fragment of 551 base pairs which includes coding sequences for amino acids 24–191 of HGH. We planned to clone this cDNA fragment and to clone separately a chemically synthesised DNA 'adaptor' fragment containing an ATG initiation codon and coding sequences for residues 1–23 of HGH. These two DNA fragments would be combined to form a synthetic–natural 'hybrid' gene. When inserted into a plasmid downstream from a uitable bacterial promoter and ribosome binding site, this gene uld be expected to direct the synthesis of fMet-HGH. The fact [illegible] most bacterial proteins do not contain N-terminal ionine residues suggests that the fMet should be efficiently ed, resulting in the direct expression of HGH.

[illegible] are several advantages of this approach over con- [illegible] expression methods which utilise either chemically [illegible] DNA or cDNA exclusively. The cDNA approach has been used to express several fused proteins (β-lactamase–rat proinsulin[6], β-lactamase–rat pre-growth hormone[7] and β-galactosidase–chicken ovalbumin[8,9]) in *Escherichia coli* which still retain antigenic activity, but which cannot be easily processed to give the natural gene product. However, the cloning of mouse dihydrofolate reductase cDNA into G-tailed, *Pst*I-cleaved pBR322 resulted in the expression of a protein which appeared to be dihydrofolate reductase[10]. This protein could have been derived from the proteolytic cleavage of a β-lactamase–dihydrofolate reductase fused protein or from the direct initiation of translation at the dihydrofolate reductase ATG (AUG) start codon. Neither of these possibilities could be relied on for HGH expression. *In vivo* proteolytic cleavage of a fused bacterially produced protein to give HGH is highly unlikely, and initiation of translation at an HGH start codon would be expected to yield the pre-hormone containing an extra 26 amino acids. The alternative approach of complete chemical synthesis of genes, although shown to be extremely effective for the bacterial production of the human peptides somatostatin[11] and insulin[12], would be very time consuming for a polypeptide as large as HGH.

Construction and cloning of plasmids containing HGH DNA sequences

The plan for the chemical synthesis of DNA designed to code for the first 24 amino acids of HGH is shown in Fig. 1*a*. To facilitate joining to HGH cDNA, the synthetic plan incorporates the same *Hae*III restriction site at amino acid residues 23 and 24 that is found in the cDNA. The 12 indicated deoxyoligonucleotides (Fig. 1*a*) were synthesised by the improved phosphotriester method essentially as described previously for insulin[13]. Figure 1*b* summarises the steps involved in the assembly and cloning of these DNA fragments in pBR322 (ref. 15). Many transformants of *E. coli* 294 (ref. 16) were obtained with plasmids containing *Eco*RI–*Hin*dIII inserts of approximately the desired size. The nucleotide sequences of three of these inserts were determined. One, pHGH3, had the expected DNA sequence. The other two had a deletion of the $A \cdot T$ base pair at the third nucleotide position for the codon of amino acid 5 (Pro).

The construction of the plasmid (pHGH31) containing the *Hae*III cDNA fragment of HGH is outlined in Fig. 2. Total poly(A)-mRNA from human pituitaries was used in the synthesis of ds-cDNA by RNA-dependent DNA polymerase (reverse transcriptase) and DNA polymerase I Klenow fragment. The cDNA was treated with *Hae*III restriction endonuclease and DNA of about 550 base pairs was purified by gel electrophoresis. This DNA fraction was then 'tailed' with deoxyC residues using terminal deoxynucleotidyl transferase[10] and cloned in pBR322 DNA which had been cleaved with *Pst*I and extended with deoxyG residues. This procedure restores the *Hae*III restriction sites on the cDNA and regenerates *Pst*I sites at both ends of the insert. Approximately 200 transformants of *E. coli* χ1776 (ref. 20) were obtained from 1 ng of C-tailed cDNA. These colonies were screened for the presence of HGH

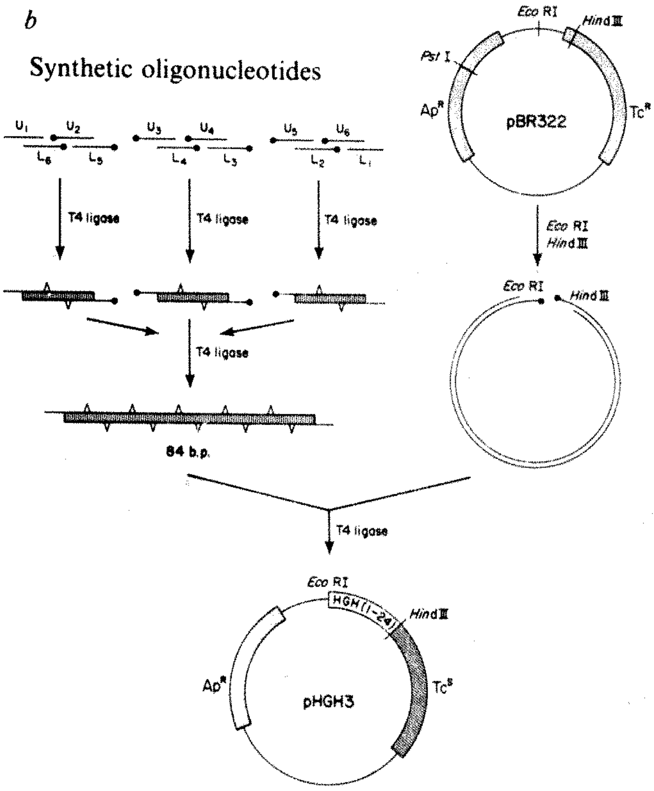

Fig. 1 Design and molecular cloning of chemically synthesised DNA coding for the first 24 amino acids of human growth hormone. *a*, The synthetic plan. The 5′ ends have single-stranded cohesive termini for the *Eco*RI and *Hin*dIII restriction endonucleases to facilitate plasmid construction. The methionine codon at the left end provides a site for initiation of translation. Twelve different oligonucleotides, varying in size from undecamer to hexadecamer, were synthesised by the improved phosophotriester method[13]. These oligonucleotides, U_1 to U_6 and L_1 to L_6, are indicated by arrows. *b*, Assembly of chemically synthesised DNA fragments and construction of plasmid pHGH3 containing a 84-base pair insert coding for HGH amino acids 1–24. Aliquots of 10 µg of U_2–U_6 and L_2–L_6 were phosphorylated using T_4 polynucleotide kinase and [γ-^{32}P]ATP (NEN) by a procedure of D.V.G.[12]. Three separate T_4 ligase-catalysed joining reactions were performed: 10 µg of 5′-OH fragment U_1 was combined with the phosphorylated U_2, L_5 and L_6; phosphorylated U_3, U_4, L_3 and L_4 were combined; and 10 µg of 5′-OH fragment L_1 was combined with the phosphorylated L_2, U_5 and U_6. These ligations were carried out at 4 °C for 6 h in 300 µl of 20 mM Tris-HCl (*p*H 7.5), 10 mM $MgCl_2$, 10 mM dithiothreitol, 0.5 mM ATP using 20 units of T_4 ligase. The three ligation mixtures were then combined, 20 units of T_4 ligase added, and the reaction allowed to proceed for 12 h at 20 °C. The mixture was ethanol-precipitated and electrophoresed on a 10% polyacrylamide gel. The band migrating at 84 base pairs (bp) was sliced from the gel and eluted[14]. Plasmid pBR322 (ref. 15) (1 µg) was treated with *Eco*RI and *Hin*dIII, the large fragment isolated by gel electrophoresis and ligated to the synthetic DNA[12]. This mixture was used to transform *E. coli* 294 (ref. 16). The *Eco*RI–*Hin*dIII insert of pHGH3 had the correct sequence as determined by the Maxam–Gilbert method[14].

sequences by the Grunstein–Hogness hybridisation procedure[21] using ^{32}P-labelled human chorionic somatomammotropin cDNA[22] as probe. Seven colonies hybridised specifically with the probe, which is nearly identical to HGH in nucleotide sequence[5]. Three had identical *Hae*III inserts of approximately 550 base pairs containing *Sma*I, *Bgl*II, *Pst*I and *Pvu*II sites, all characteristic of HGH cDNA[5]. Sequence analysis of the insert from one of these clones, pHGH31 (Fig. 3) gave only one discrepancy (CUG versus CUA codon for leucine 101) when compared with the previously determined cDNA sequence[5]. The amino acid sequence derived from the cDNA sequence differs from the published amino acid sequences of Li[23] at positions 74 (Glu versus Gln), 107 (Asp versus Asn) and 109 (Asn versus Asp). Although we cannot rule out post-transcriptional modification, the discrepancies probably stem from shortcomings of earlier protein sequencing methods in the identification of amidated amino acids.

Construction and cloning of HGH expression plasmids

To express directly HGH in *E. coli*, a plasmid (pGH6) having two *lac* promoters was constructed as follows. A 285-base pair *Eco*RI fragment containing two 95-base pair UV-5 *lac* promoter fragments separated by a 95-base pair heterologous DNA fragment was isolated from the plasmid pKB268 (ref. 24) and inserted into pBR322 at the *Eco*RI site. A plasmid (pGH1) was isolated with the promoter orientated to initiate transcription in the direction of the tetracycline resistance (tc^R) gene. The *Eco*RI site distal to the tc^R gene was destroyed by a previously outlined procedure[11].

Figure 4 reviews the steps involved in assembling the two separately cloned HGH DNA fragments. Treatment of pHGH3 with *Eco*RI and *Hae*III gives a 77-base pair fragment with an *Eco*RI cohesive end and a *Hae*III blunt end (also see Fig. 1*a*). This fragment, which codes for HGH amino acids 1–23, was isolated from a polyacrylamide gel. The plasmid pHGH31 was cleaved with *Hae*III and the 55-base pair HGH cDNA fragment isolated by gel electrophoresis. *Xma*I treatment of this fragment yielded a 512-base pair fragment coding for amino acids 24–191 of HGH with one *Hae*III blunt end and one *Xma*I sticky end. The ligation of these two fragments resulted in the formation of high molecular weight DNA. Treatment with *Sma*I (which recognises the same sequence as *Xma*I but leave flush ends) and *Eco*RI converted the ligation products to three distinct fragments: a 154-base pair dimer of the 77-base pair DNA fragment, a 1,024-base pair dimer of the 512-base pair fragment, and the desired 591-base pair DNA coding for the entire HGH sequence. This latter fragment was purified by gel electrophoresis and inserted into pGH6 between the *Eco*RI and the S_1 nuclease-treated *Hin*dIII sites. Following transformation of χ1776, the expression plasmid pHGH107 was identified by colony screening and restriction analysis as described in Fig. 3. The HGH DNA sequence of pHGH107 was verified by the Maxam–Gilbert procedure[14].

In our plan to express HGH two base pairs were included between the *Eco*RI AATT 'sticky' end and the ATG codon of the chemically synthesised portion of the HGH coding sequence (see Fig. 1). Therefore, in the plasmid pHGH107, 11 base pairs separate the *lac* AGGA ribosome binding site[26] and the ATG translational start for HGH:

$$5'\ldots\overline{\text{AGGA}}\,\text{AACAG}|\underline{\text{AATT}}\,\text{CT}\,\overline{\text{ATG}}\ldots$$
$$3'\ldots\text{TCCTTTGTCTTAA}|\text{GATAC}\ldots$$

In the naturally occurring *lac* system the separation between

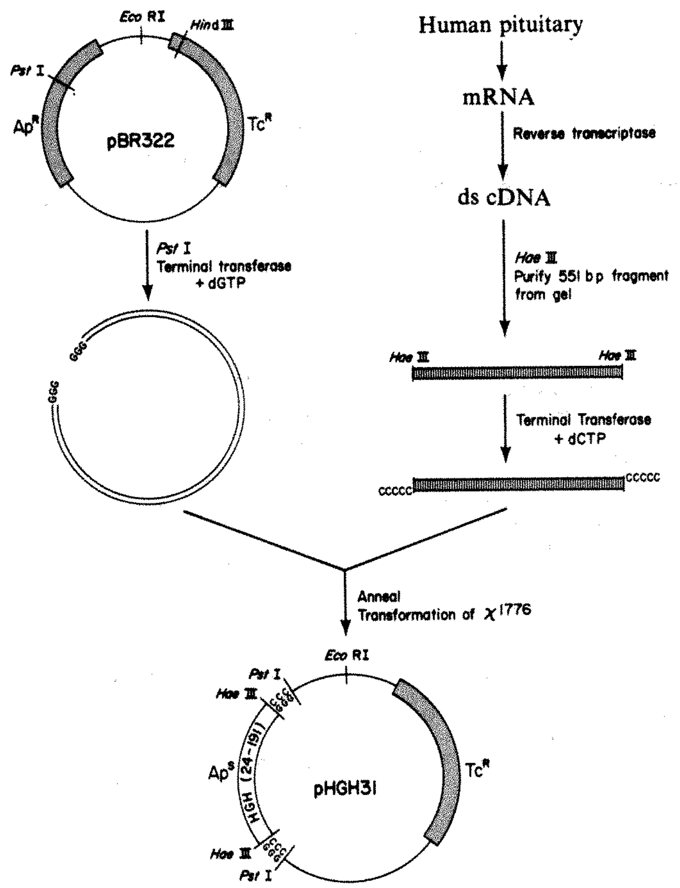

Fig. 2 Construction of a plasmid (pHGH31) containing coding sequences for amino acids 24–191 of human growth hormone. Poly(A)-mRNA was prepared from human pituitaries by a published procedure[17]. ds-cDNA (1.5 μg) was prepared from 5 μg of this RNA essentially as described by Wickens *et al.*[18], except that DNA polymerase 'Klenow fragment'[19] was substituted for DNA polymerase I in the second strand synthesis. cDNA (90 ng) was treated with *Hae*III, electrophoresed on an 8% polyacrylamide gel, and the region around 550 base pairs eluted. Approximately 1 ng of cDNA was obtained. Terminal deoxynucleotidyl transferase (TdT) was used to add approximately 20 dC residues per 3′ terminus[10]. Annealing of the dC-tailed ds-cDNA with the dG-tailed vector DNA (60 ng) was performed in 130 μl of 10 mM Tris-HCl (pH 7.5), 100 mM NaCl, 0.25 mM EDTA. The mixture was heated to 70 °C, allowed to cool slowly to 37 °C (12 h), then to 20 °C (6 h), before being used to transform χ1776 (ref. 20) by a published procedure[4].

ribosome binding site and initiation codon is 7 base pairs. The exact *lac* sequence in this region was restored as follows. The plasmid was cleaved with *Eco*RI, treated with S_1 nuclease to digest the single stranded ends, and reclosed by blunt-ended ligation. The plasmids from three individual transformants of χ1776 were analysed. In all instances the *Eco*RI site had been removed and a new *Alu*I site created in the plasmid (pHGH107–1).

$$5'\ldots\overline{\mathrm{AGGA}}\,\mathrm{AACAG}\,\vert\,\mathrm{CT}\,\overline{\mathrm{ATG}}\ldots$$
$$3'\ldots\mathrm{TCCTTTGTC}\,\vert\,\mathrm{GATAC}\ldots$$

This structure, in which the ATG codon is now seven nucleotides downstream from the ribosome binding site, might be expected to increase the efficiency with which HGH mRNA is translated.

HGH radioimmune activity in bacterial extracts

Extracts of *E. coli* χ1776 containing the expression plasmids were tested for HGH expression by a direct radioimmunoassay (RIA) (Table 1). Easily detectable amounts of HGH were produced by bacteria containing pHGH107 or the derivative of pHGH107 lacking the *Eco*RI site (pHGH107–1). Contrary to

Fig. 3 The amino acid and mRNA sequences of HGH as determined by DNA sequencing[14] of pHGH31. The nucleotide sequence from the *Sma*I site to the *Hae*III site in the 3′ noncoding region is from ref. 5, and was not determined here.

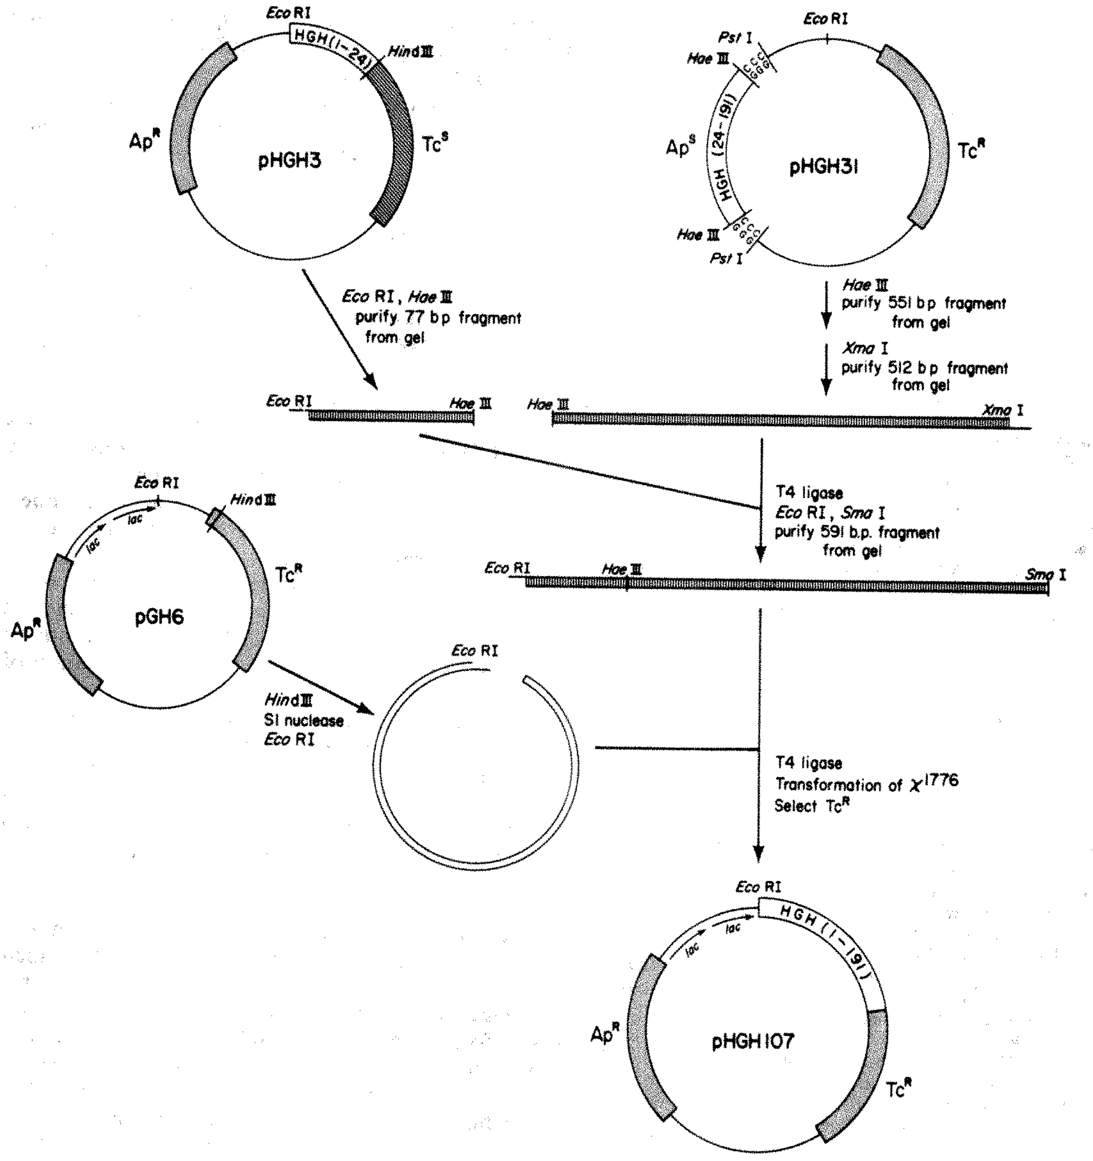

Fig. 4 Construction of a plasmid (pHGH107) for the bacterial expression of human growth hormone. pHGH3 (10 μg) was cleaved with *Eco*RI and *Hae*III restriction endonucleases and the 77-base pair fragment containing coding sequences for HGH amino acids 1–23 was isolated from an 8% polyacrylamide gel. The plasmid pHGH31 (~5 μg) was cleaved with *Hae*III. The 551-base pair HGH sequence and a co-migrating 540-base pair *Hae*III fragment of pBR322 were purified by gel electrophoresis. Subsequent treatment with *Xma*I cleaved only the HGH sequence, removing 39 base pairs from the 3′ noncoding region. The resulting 512-base pair fragment was purified from the 540-base pair pBR322 *Hae*III piece by electrophoresis on a 6% polyacrylamide gel. Samples of 0.3 μg of the 77-base pair *Eco*RI–*Hae*III fragment and 0.3 μg of the 512-base pair *Hae*III–*Xma*I fragment were polymerised with T_4 DNA ligase in a 16-μl reaction for 14 h at 4 °C. The mixture was heated at 70 °C for 5 min to inactivate the ligase, then treated with *Eco*RI (to cleave fragments which had dimerised through their *Eco*RI sites) and with *Sma*I (to cleave *Xma*I dimers), yielding a 591-base pair fragment with an *Eco*RI 'sticky' end and a *Sma*I 'blunt' end. After purification on a 6% polyacrylamide gel, approximately 30 ng of this fragment were obtained. The expression plasmid pGH6 containing tandem *lac* UV-5 promoters, was treated successively with *Hin*dIII, nuclease S_1, and *Eco*RI and purified by gel electrophoresis. This removes most of the promoter sequence of the tc^R gene, but leaves the structural gene intact (25). 50 ng of the resulting vector, which had one *Eco*RI sticky end and one blunt end, was ligated to 10 ng of the 591-base pair HGH DNA. The ligation mixture was used to transform χ1776. Colonies were selected for growth on tetracycline (12.5 g ml^{-1}). Since the tc^R promoter is no longer functional, tetracycline resistance is dependent on transcription from the *lac* promoters reading through the HGH gene sequence into the tc^R gene. Approximately 400 transformants were obtained. Colony screening by filter hybridisation[22] identified 12 colonies containing HGH sequences. The plasmids isolated from three of these colonies gave the restriction patterns expected for the correctly assembled gene when cleaved with *Hae*III, *Pvu*II and *Pst*I. The DNA sequence of one clone, pHGH107, was determined.

our expectations, the introduction of four extra base pairs of DNA into the *lac* sequence in the region between the ribosome binding site and initiation codon results in increased HGH synthesis.

To verify that HGH expression is under *lac* operon control the plasmid pHGH107 was transformed into the *E. coli* K12 strain D1210, an i^Q derivative of *E. coli* K12 HB101 which overproduces *lac* repressor[12]. The data in Table 1 demonstrate that repressor effectively blocks HGH production and that this effect can be reversed by the addition of the inducer isopropyl-β-D-thiogalactoside.

Identification of HGH from bacterial extracts

Extracts of *E. coli* K12 strain RV308 (ref. 27) containing either pHGH107 or pBR322 were electrophoresed on SDS-polyacrylamide gels. The resulting protein patterns show one clear difference (Fig. 5*a*)—an additional protein, which co-migrates with HGH isolated from pituitaries, appears in the RV308/pHGH107 extract. To achieve partial purification of HGH, an extract of a 1-litre culture of χ1776/pHGH107 was prepared and fractionated as described in Fig. 5 legend. The polyacrylamide gel electrophoresis pattern of this partially

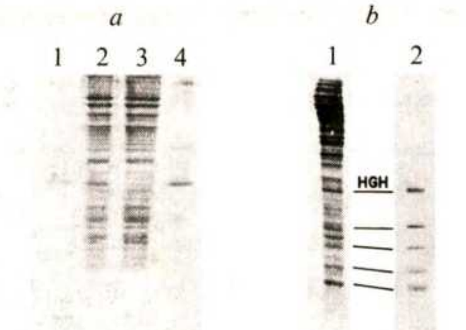

Fig. 5 Identification of HGH produced in bacteria by SDS-polyacrylamide gel electrophoresis. *a*, Protein patterns of crude extracts and partially purified HGH stained with Coomassie brilliant blue. Slot 1 contains 0.5 μg of pituitary HGH standard (Kabi), slot 2 contains a cell lysate of RV308/pHGH107, slot 3 contains a cell lysate of RV308/pBR322, slot 4 contains partially purified HGH isolated from χ1776/pHGH107. The samples were separated on a 15% polyacrylamide slab gel using the buffer system of Maizel[28] with the addition of 6 M urea. Crude lysates were prepared by growing cells in LB with 5 $\mu g\ ml^{-1}$ tetracycline followed by lysis in 2% SDS, 1% β-mercaptoethanol. The lysates were precipitated with 10 volumes of cold acetone and the pellets were redissolved in SDS sample buffer for use in gel electrophoresis. The partially purified HGH was prepared from a stationary phase culture of χ1776/pHGH107. Cells were collected and resuspended in 1/50 of their original volume in 30 mM potassium phosphate (*p*H 7.0) containing 0.05 M NaCl and lysed by sonication. Polyethylenimine (Miles, Polymin-P) was added to 0.2%. After centrifugation for 1 h at 100,000*g*, ammonium sulphate was added to the supernatant to 60% saturation. The ammonium sulphate pellet was dissolved in 2 ml 10 mM potassium phosphate (*p*H 7.0), 0.5 M NaCl and chromatographed on a Sephacryl S-200 column (2.0 × 50 cm) equilibrated in the same buffer. The radioimmune active peak (assayed with a Pharmacia Phadebus HGH kit) was pooled, the protein concentrated by ammonium sulphate precipitation, the pellet redissolved in 1/10 volume of buffer, and the solution dialysed against 10 mM potassium phosphate (*p*H 7.0), 0.5 M NaCl. Precipitated material was removed by centrifugation resulting in a HGH preparation of approximately 25% purity. *b*, Autoradiograms of ^{35}S-labelled extracts of RV308/pHGH107. Slot 1 contains a total lysate of RV308/pHGH107 labelled with $H_2{}^{35}SO_4$. Slot 2 contains an ^{35}S-labelled extract of RV308/pHGH107 precipitated with α-HGH antiserum. The major (top) band co-migrates with unlabelled HGH standard (not shown). Cultures (1 ml) of RV308/pHGH107 were grown to $A_{550} = 1$ in low sulphur medium[29] containing 0.2 $mCi\ ml^{-1}$ $H_2{}^{35}SO_4$, chased with 10 mM $MgSO_4$ for 5 min, collected and lysed using Triton X-100 and lysozyme[30]. Following DNase and RNase treatment[29], the lysate was mixed with a 10-fold excess of unlabelled RV308/pBR322 extract and diluted 1:1 into Triton immunoprecipitation buffer (0.15 M NaCl, 1% Triton X-100, 0.05 M Tris-HCl *p*H 7.5). Twenty μl of α-HGH antiserum (Kabi) was added per ml of original culture and the reaction was incubated for 12 h at 4 °C. The mixture was centrifuged and the supernatant incubated for 2 h with formaldehyde fixed *Staphylococcus* cells[31], filtered on 0.45-μm Nucleopore polycarbonate filters, washed with Triton immunoprecipitation buffer and extracted with SDS sample buffer[28]. The samples were run on a 15% slab gel containing urea and SDS as described above.

purified sample is shown in Fig. 5*a*, slot 4. The most prominent band co-migrates with HGH standard and its relative intensity is consistent with the 25% purity calculated from radioimmune activity.

In an independent attempt to confirm that the antigenically active component in the bacterial extracts co-migrates with HGH in SDS gels, we precipitated extracts from cells labelled with ^{35}S with antiserum prepared against HGH and separated the precipitated proteins by polyacrylamide gel electrophoresis. The autoradiogram of the immunoprecipitated material (Fig. 5*b*, slot 2) shows a major band, with electrophoretic mobility identical to that of HGH, as well as four smaller bands. All five of these bands are present in the unfractionated ^{35}S-labelled lysate (slot 1), whereas only the band with the same mobility as HGH can be seen in unlabelled extracts of cells grown in LB broth (Fig. 5*a*, slot 2). All five immune precipitated bands can be competed out by excess cold HGH (data not shown) and are thus antigenically related. This suggests that the four smaller HGH-related products observed in minimal media may be due to proteolytic degradation.

Additional evidence of proteolytic degradation of HGH is presented in Table 1. The levels of HGH in extracts from strains containing pHGH107 or pHGH107–1 were considerably higher in log-phase cultures than in stationary-phase cultures. Strains transformed with several other plasmids whose products are under *lac* promoter control show no comparable decrease of gene expression as a function of growth phase (unpublished results from this laboratory). It thus seems that there is some turnover of HGH in bacterial cells although we cannot rule out other explanations for the four smaller HGH-related products in the ^{35}S-labelled extracts such as premature termination of translation.

Despite the observed instability of HGH in certain growth conditions, the molecule seems to be relatively stable in log-phase cultures grown in rich media. In these conditions the amount of HGH in the cells (186,000 monomers per cell, Table 1) compares favourably with the expression level of other cloned genes using the same promoter in optimised conditions[32].

Conclusion

Using a novel combination of chemically synthesised DNA and cDNA, a recombinant *E. coli* strain has been constructed which produces HGH in large amounts. This is the first time that a human polypeptide has been directly expressed in *E. coli* in a non-precursor form. The hybrid DNA cloning techniques described as a route to the cloning and expression of HGH coding sequences in *E. coli* are generally applicable to other polypeptides which are synthesised initially as inactive precursors and later processed, or for which full length cDNA transcripts are unavailable.

We thank John Shine for help in planning the project, Elizabeth McLeod for assistance, Ron Wetzel for help in peptide identification, Frances Fields and Dale Cullins for technical support, Alane Gray for preparing illustrations, and Robert Swanson and Herbert Boyer for their encouragement. RNA used was prepared by P.H.S. while a postdoctoral fellow in the Department of Biochemistry and Biophysics, University of California at San Francisco. Additional RNA was obtained from pituitaries donated by Drs Gerald Silverberg and O. H. Pearson. This work was supported by a contract from KabiGen AB. All experiments involving recombinant genomes were performed in accordance with current NIH guidelines.

On the isotropy and homogeniety of the Universe

Michael S. Turner

Astronomy and Astrophysics Center, Enrico Fermi Institute,
The University of Chicago, Chicago, Illinois 60637

It is generally believed that the Universe began from a hot big bang. Among the clues to its very early history are the present day observations that the Universe is isotropic and homogeneous (as shown by the 3 K microwave background[1] and galaxy counts[2,3]) and that there are about $10^{9\pm1}$ photons per baryon[4]. Penrose and others[5,6] argue that these two observations imply that the Universe was initially very nearly isotropic and homogeneous. Their arguments rely on absolute baryon conservation so that the baryon number of the Universe can be used as a fiducial to which the number of photons can be compared. In recently proposed grand unified theories of particle interactions, baryon number is not absolutely conserved[7,8] and thus the baryon number of the Universe is no longer a constant. It is argued here that in the absence of this fiducial the photon/baryon ratio is not a 'footprint' of the initial conditions, and therefore the initial singularity could well have been highly irregular as Misner suggested[9].

The photon/baryon ratio is also ≃ the entropy/baryon ratio (more precisely, the specific entropy/baryon ratio) as nearly all the photons in the Universe are in the 3 K background. Misner suggested that the seemingly large entropy/baryon and the remarkable isotropy and homogeneity are related. His idea is that the initial singularity, rather than being isotropic and homogeneous, was highly irregular (chaotic), and the matter was cold (small entropy per baryon). Then, dissipative processes (pair creation, neutrino viscosity, and so on) smoothed out the irregularities and in the process also generated the large entropy/baryon. This is an attractive idea for several reasons. The Universe begins from a very general initial state (rather than isotropic and homogeneous), evolves into the observed state of isotropy and homogeneity, and thereby generates the observed entropy/baryon. However, calculations by Barrow and Matzner[5] and arguments by Penrose[6] indicate that in the process of dissipating irregularities, an initially highly chaotic geometry would generate more like 10^{40} photons/baryon. Therefore, they conclude that the observed entropy/baryon of $10^{9\pm1}$ implies that the initial geometry was very nearly isotropic and homogeneous.

This reasoning relied on comparing the entropy (number of photons) to an unchanging, non-zero number (in this case, the number of baryons in the Universe). However, recent theories in particle physics suggest that baryon number is not an exactly conserved quantity. The grand unification of the strong, weak and electromagnetic forces by a gauge theory seems to require that baryon and lepton conservation be abandoned[7,8]. Unification puts quarks and leptons in the same multiplets, and therefore interactions exist which transform them into one another. In these theories baryon violating interactions are mediated by a super heavy boson (mass $m_x \gtrsim 10^{14}$ GeV) and are almost negligible at low energies (the proton is nearly stable). However, these interactions would be of roughly the same strength as all the other interactions at energies above $\sim m_x (\gtrsim 10^{14}$ GeV, temperatures above $\sim 10^{27}$ K). Several authors[10–17] have shown that these baryon non-conserving interactions along with CP violation (K^0–$\bar{K}^0$ system is known to violate CP) allow an intially hot ($T = 10^{32}$ K, the Planck temperature), baryon symmetric (net baryon number zero), isotropic ahd homogeneous Universe to evolve a net baryon excess when kT is $\sim m_x$. For reasonable values of the particle physics parameters the excess/entropy can be $\sim 10^{-9\pm1}$, and thus when the baryons and antibaryons annihilate, the Universe is left with $10^{-9\pm1}$ baryons per photon as we observe today. In addition, these grand unification theories predict a finite lifetime for the proton of $10^{31\pm1}$ years[18] which may soon be accessible to measurement. The current lower limit on the lifetime of the proton is 10^{29} yr (ref. 19).

If these ideas are correct there may no longer be a conserved, non-zero quantity to which the entropy can be compared, and therefore the entropy cannot be used as a probe of the initial geometry of the Universe. For example, the Universe could have begun from a state with highly chaotic geometry and a definite number of cold baryons; very early ($t \sim t_{\text{planck}} \sim 10^{-43}$ s, $T \sim 10^{32}$ K), dissipative processes smoothed out the irregularities leaving the Universe isotropic and homogeneous, and with an entropy/baryon of $\sim 10^{40}$. When the temperature of the Universe dropped to about 10^{27} K ($kT \sim 10^{14}$ GeV) the baryon number and CP violating processes allowed the Universe to evolve a baryon/photon ratio of $\sim 10^{-9\pm1}$ erasing the only relic (baryon/entropy ratio $\sim 10^{-40}$) of a highly chaotic initial state.

One key assumption was tacitly made in the argument above: dissipation occurs before baryon generation. This assumption is needed because the baryon generation routes suggested thus far assume that the Universe is isotropic and homogeneous during the epoch of baryon creation ($kT \sim m_x$). In addition, any dissipation which occurs after the baryon excess is generated cannot be masked, as baryon number is very nearly conserved from that point forward. Thus we require dissipation to occur at a temperature $\gtrsim m_x/k$ ($\gtrsim 10^{27}$ K). It has been pointed out that dissipative processes during the quantum gravity epoch ($t \sim 10^{-43}$ s, $T \sim 10^{32}$ K) would have been highly efficient in dissipating chaos[5,6], so that it is reasonable to believe that the Universe was isotropic and homogeneous for temperatures $\lesssim 10^{32}$ K. Barrow is also considering the case when the dissipation does not precede the baryon generation (personal communication).

If the dissipation occurs early enough, a new, non-zero conserved quantity is needed to gain knowledge of the initial geometry. In some of the candidate theories for grand unification in addition to charge, some other number may be absolutely conserved, usually $B-L$ (B is baryon number, L is total lepton number). Suppose that the net charge of the Universe is zero, that the charged particles of the Universe are protons and electrons, and that the leptons of the Universe are electrons, and the neutrinos and anti-neutrinos in the 2 K neutrino background. Assuming further that the number of neutrinos and anti-neutrinos are exactly equal, the lepton number of the universe is equal to the number of electrons. Since the number of neutrons is about 1/7 the number of protons, the net $B-L$ number of the Universe is, within an order of magnitude, equal to the baryon number of the Universe. Then once again there is a conserved, non-zero quantity to compare to the entropy and it is possible to use the observed (net $B-L$)/photon ratio (of $\sim 10^{-9}$) to infer that the Universe began from a nearly isotropic and homogeneous initial state.

However, it is not easy to measure the lepton number of the Universe since the 2 K neutrino background is not detectable

0028–0836/79/420549—02$01.00

with present technology. Starting with the same assumptions as above except for the ratio of neutrinos to anti-neutrinos in the 2 K background which this time differs from 1 by $\sim +10^{-9}$: then for every $\sim 10^9$ photons there is one more neutrino than anti-neutrino. In this case the neutrino background contributes to the (net $B-L$)/photon $\sim -10^{-9}$, thereby reducing the (net $B-L$)/photon to nearly zero (say to 10^{-40}), whereas the visible (electrons, protons and neutrons) (net $B-L$)/photon is still $\sim 10^{-9}$. Therefore, while in principle the conserved quantity $B-L$ could be used to infer whether or not the initial geometry was isotropic and homogeneous, in practice, our inability to detect 2 K neutrinos makes this impossible.

The present day isotropy and homogeneity, and baryon/photon ratio of the Universe are important clues to the early history of the Universe. If a non-zero conserved quantity exists (such as baryon number), these two observations, as Penrose and others have pointed out, seem to imply the initial geometry of the Universe was nearly isotropic and homogeneous. However, if the grand unification ideas are correct and the baryon/photon ratio of $10^{-9\pm1}$ is generated in this way, then observed baryon/photon ratio, and the present isotropy and homogeneity do not allow us to infer that the initial geometry of the Universe was very nearly isotropic and homogeneous. In fact, the initial geometry could well have been highly chaotic.

I thank James Hartle and David Schramm for helpful comments. This work was supported by an Enrico Fermi Fellowship at the University of Chicago and by NSF grant AST 78-20402.

Quasar image doubling associated with absorption systems

Julian H. Krolik

Institute for Advanced Study, Princeton, New Jersey 08540

John Kwan

Bell Laboratories, Murray Hill, New Jersey 07974

Ever since their discovery the origin of quasar absorption lines has been a subject of considerable controversy (see ref. 1). In this note we consider the consequences of the hypothesis that at least some of the absorption lines arise in galaxies. These galaxies could be ordinary ones with 50–100 kpc haloes[2], or perhaps more compact but more common (at $z \sim 1$–2) objects of comparable mass.

In addition to selectively absorbing light of certain wavelengths, galaxies bend the path of the light by gravitational attraction. In the weak field approximation, the amount of bending in passing a point mass M at a distance l_P is $4M/l_P$ in units $G=c=1$ (ref. 3); if the mass is distributed and the light ray passes within it, the deflection, for the same total mass, can be slightly different depending on the details of the distribution[9,10]. The order of magnitude of the deflection angle in passing through a galaxy is $\sim 0.6''(\Delta v/250\ \mathrm{km\ s^{-1}})^2$, where $\Delta v = (GM/l_p)^{1/2}$ is the typical orbital speed in the galaxy. Such a small amount is invisible to ground-based optical telescopes (though not by a large factor), but should be easily discernible by either the Very Large Array (VLA) or the Space Telescope. We suggest, therefore, that those quasars with well defined absorption systems should be searched for gravitationally-focused multiple images.

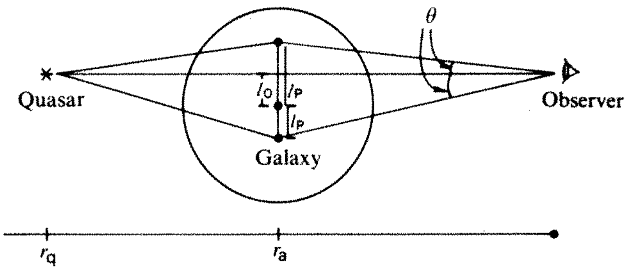

Fig. 1 The ray geometry is obviously not to scale. For precise definitions of the labels see text.

More precisely, we suppose that an absorption system of redshift z_a implies the presence of a galaxy at that redshift. We may find the angle by which the ray reaching Earth differs from the undeflected line of sight past the galaxy from the expression[4]:

$$4\left(\frac{\Delta v}{c}\right)^2 f(l_p)\frac{r_a r_{aq}}{(1+z_a)r_q} = l_p \mp l_0 = \frac{r_a\theta}{1+z_a} \tag{1}$$

where f is a slowly varying function of order unity whose form depends on the shape of the galaxy mass distribution; r_a and r_q are the comoving radial coordinates of the galaxy and the quasar, respectively, with respect to the observer as origin, whereas r_{aq} is the comoving radial coordinate of the galaxy with respect to the quasar as origin; l_0 is the proper distance from the centre of the galaxy to the undeflected line of sight and l_p is the proper pericentre distance of the ray; and $\theta (\ll 1)$ is the angle between the undeflected line of sight and the received ray (see Fig. 1). Here we have made the approximation that $l_p \simeq \pm l_0 + (r_a\theta)/(1+z_a)$; it is actually slightly less. The '±' correspond to paths that lie on the same, or opposite, sides of the galaxy's centre as the undeflected line of sight. We have also assumed that there is no other scattering along the ray path. In cosmologies which are homogeneous only in the mean so that the rays propagate in empty space but are subjected to many weak scatterings[5,6], the results differ by <10%.

The function $f(l_p)$ accounts for the galaxy's mass distribution. If it is spherically symmetric and has a flat velocity curve from inside l_p out to a radius l_1 (but has no mass outside l_1), then we have (for $l_p < l_1$):

$$f(l_p) = \tfrac{1}{2}\left(\cos^{-1}(l_p/l_1) + 2(l_1/l_p)\{1-[1-(l_p/l_1)^2]^{1/2}\}\right)$$
$$\simeq \begin{cases} \tfrac{1}{4}[\pi + \tfrac{1}{6}(l_p/l_1)^3] & l_p/l_1 \ll 1 \\ 1 & (l_1-l_p)l_1 \ll 1 \end{cases} \tag{2}$$

If $l_p \geqslant l_1$, $f(l_p) = l_1/l_p$.

The easiest way to find the actual splitting angle (given l_0, Δv, and the cosmological information) is to use the graphical construction of Fig. 2. The splitting angle is:

$$\theta_{\mathrm{sep}} = 4[f(l_{p+}) + f(l_{p-})]\left(\frac{\Delta v}{c}\right)^2 \frac{r_{aq}}{r_q}$$
$$\simeq 0.9'' r_{aq}/r_q \left(\frac{\Delta v}{250\ \mathrm{km\ s^{-1}}}\right)^2 \tag{3}$$

0028–0836/79/420550—02$01.00

where $l_{p\pm}$ are given by the two intersections of the straight lines with the curve in Fig. 2.

Clearly, there are only solutions for both l_{p+} and l_{p-} if:

$$l_0 \leqslant \pi\left(\frac{\Delta v}{c}\right)^2 \frac{r_a r_{aq}}{(1+z_a)r_q} = 13\,\frac{r_a r_{aq} H_0}{(1+z_a)r_q c}\left(\frac{\Delta v}{250\text{ km s}^{-1}}\right)^2 \times\left(\frac{H_0}{50\text{ km s}^{-1}\text{ Mpc}^{-1}}\right)^{-1}\text{kpc} \qquad (4)$$

To evaluate this limit, we note that[3]:

$$r_a = \frac{c}{H_0(1+z_a)q_0^2}\{z_a q_0 + (q_0-1)[-1+(1+2q_0 z_a)^{1/2}]\} \qquad (5)$$

with an analogous expression obtaining for r_q, while

$$r_{aq} = \frac{c}{H_0 q_0^2(1+z_a)(1+z_q)}[(1-q_0+q_0 z_q)(1+2q_0 z_a)^{1/2} - (1-q_0+q_0 z_a)(1+2q_0 z_q)^{1/2}] \qquad (6)$$

where z_q is the quasar redshift and q_0, H_0 are evaluated at the present epoch. For 'typical' numbers ($q_0 \leqslant 0.1$, $0.5 \leqslant z_a$, $z_q \leqslant 3.5$), the maximum undeflected impact parameter that will produce a double image is only

$$\sim 2\left(\frac{\Delta v}{250\text{ km s}^{-1}}\right)^2\left(\frac{H_0}{50\text{ km s}^{-1}\text{ Mpc}^{-1}}\right)^{-1}\text{kpc}$$

(see Table 1).

Consequently, only a small fraction, $\langle (l_{0,\max}/l_1)^2\rangle$, of all absorption systems will produce double images. To produce the six or so absorption systems which are commonly found in quasars of $z_q \gtrsim 2$,

$$l_1 \simeq 100\text{ kpc}\left(\frac{H_0}{50\text{ km s}^{-1}\text{ Mpc}^{-1}}\right)^{-1}$$

(ref. 7). This estimate of l_1 assumes the present number density of galaxies and no galaxy–quasar correlations; it would decrease if the density of objects gravitationally bound as tightly as galaxies and at least a few kiloparsecs in size were greater at $z \sim 1$–3, or if correlations do exist. Using $l_1 \simeq 100$ kpc, we estimate the probability per absorption system that a double image is formed to be $O(10^{-3})$. Unfortunately, the close approach of the rays to the galaxy centre also entails the hazard that visible wavelengths may be extinguished by dust, or that the surface brightness of the galaxy may mask the quasar images.

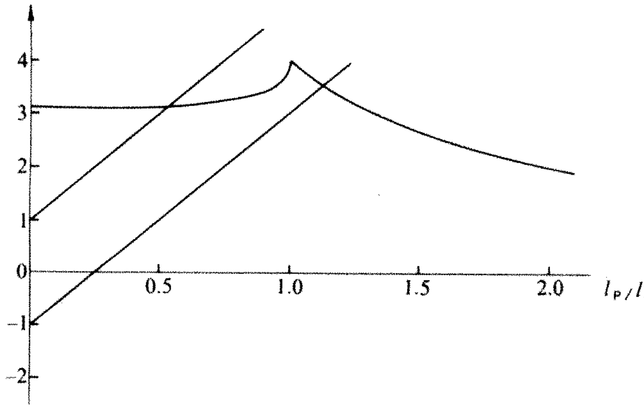

Fig. 2 The curve shows $4f(l_p)$ as a function of l_p/l_1 for the mass model that led to equation (2). The lines represent $(l_p \pm l_0)\cdot(1+z_a)r_q/[r_a r_{aq}(\Delta v/c)^2]$ as a function of l_p/l_1, where we have chosen the illustrative parameters:

$$\frac{r_a r_{aq}}{(1+z_a)r_q}\left(\frac{\Delta v}{250\text{ km s}^{-1}}\right)^2\left(\frac{l_1}{100\text{ kpc}}\right)^{-1}\left(\frac{H_0}{50\text{ km s}^{-1}\text{Mpc}^{-1}}\right)^{-1} = 6$$

and $l_0/l_1 = 0.25$.
Their intersections with the curve give the approximate pericentres of the received rays: $l_p/l_1 \simeq 0.53$ and 1.13. As l_0/l_1 increases, the intercepts of the straight lines with the vertical axis spread until eventually only the ray corresponding to the − sign is received.

Table 1 Sample values of θ_{sep} and the maximum ray impact parameter $l_{0,\max}$

z_a	r_a	r_{aq}	$l_{0,\max}$(kpc)	θ_{sep}(arc s)
0.25	0.22	1.04	1.76	0.69
0.5	0.41	0.81	2.10	0.54
1.0	0.71	0.50	1.70	0.33
1.5	0.95	0.29	1.06	0.19
2.0	1.17	0.13	0.49	0.086

$q_0 = 0.1$ and $z_q = 2.5(r_q = 1.364c/H_0)$
The values of r_a and r_{aq} are in units of c/H_0; $l_{0,\max}$ and θ_{sep} are calculated assuming $(\Delta v/250\text{ km s}^{-1})^2 \times (H_0/50\text{ km s}^{-1}\text{Mpc}^{-1})^{-1} = 1$.

Another way of understanding this probability estimate is to use the result[5] that if the mass of the Universe comes in many point-like objects, the probability of creating a visible double image of an object at a cosmological distance is of order Ω, the density parameter. Here, in effect, only the mass contained in the inner few kiloparsecs contributes to Ω.

There are two types of checks that may be made on a double image, to confirm that it is due to gravitational deflection. The first, which must await the Space Telescope, is to match the spectra of the two images. In general, radio spectra are too smooth to attach much significance to matching their shapes. The second is to match the images' time-variability records. The difference in path lengths will be

$$\leqslant 2\left(\frac{\Delta v}{250\text{ km s}^{-1}\text{Mpc}^{-1}}\right)^4\left(\frac{H_0}{50\text{ km s}^{-1}\text{Mpc}^{-1}}\right)^{-1}(r_{aq}/r_q)^2\text{ months,}$$

depending on how nearly symmetrical the ray paths are about the galaxy centre. Even if the two images are not resolved, the quasar can be examined for doubling by performing an autocorrelation in time of its intensity (S. Tremaine, personal communication).

The autocorrelation function will always have its strongest peak at zero delay, but if the intensities of the images are not too different, a second peak should appear that corresponds with the difference in path lengths. To estimate that intensity ratio, we use the fact that the gravitational lens conserves surface brightness. Then each image's intensity is multiplied by a factor $l_p/l_0|dl_p/dl_0|$ (ref. 8); in our case, $d\ln f(l_p)/d\ln l_0 \ll 1$, so the factor reduces to $\simeq l_p/l_0$. Thus we expect an intensity ratio of perhaps a factor of two or so, and the autocorrelation test should be feasible.

The plausible idea that at least some quasar absorption systems are made in galaxies implies that a small fraction of these galaxies will cause a doubling of the quasar image by gravitational focusing. The separation of these images ($\leqslant 1''$) should be detectable with the VLA (for radio quasars) and the Space Telescope when it flies. Autocorrelation of the variability of unresolved quasar images may also reveal doubling due to gravitational focusing.

Scaling law test and two predictions of planetary magnetic moments

C. T. Russell

Institute of Geophysics and Planetary Physics, University of California, Los Angeles, California 90024

The scaling law for the strength of planetary magnetic dynamos, originally derived from a magnetohydrodynamic (MHD) theory[1], has recently been independently re-derived using simple dimensional analysis[2]. While dimensional analysis is certainly no replacement for a solution based on a physical mechanism, this analysis does lend more credence to the scaling law by the implicit suggestion that the form of the scaling law is not an artefact of the MHD solution. We show here that the scaling law holds quite well in ordering the three well determined planetary magnetic moments. The present meagre data suggest that the terrestrial magnetic moment is about twice the value expected when compared with the other planets. Assuming that Earth is anomalous, rather than Mercury and Jupiter, and that the scaling law is valid, we predict that Saturn will be found to have a moment of 1.2×10^{29} G cm^3 and Io a moment of 6.5×10^{22} G cm^3.

Expressed in terms of magnetic moments which are the observable parameters in planetary exploration, the scaling law becomes

$$\frac{M_P}{M_E} = \left(\frac{\rho_P}{\rho_E}\right)^{1/2} \left(\frac{R_P^c}{R_E^c}\right)^4 \frac{\Omega_P}{\Omega_E}$$

where M is the magnetic moment, R^c is the radius of the core, ρ is the density of the core and Ω is the spin rate. The subscript P refers to the planet, E to the Earth. For this scaling law to work, all planetary dynamos must have the same underlying physical mechanism. We note also that the strength of the energy source for the dynamo does not appear in this scaling law. In this model if the strength of the energy source is not sufficient, the dynamo does not regenerate and then stops. If it is regenerative, it assumes a particular strength given by the scaling law. This lack of consideration of the strength of the energy source is considered by many to be grounds for rejection of any scaling law.

In the scaling law Ω is well known for all large bodies in the Solar System except for the outermost planets. However, there is much uncertainty in the core radius and density, especially for the inner planets whose chemical composition and thermal history are uncertain. Nevertheless, enough modelling has been done, and planetary measurements performed for us to be able to put this scaling law to a serious test.

The results of this test are shown in Fig. 1. For Mercury we have made the core density the same as that of the Earth and the limits on core radius to be 1,470–1,840 km (refs 3, 4). The range of the observed magnetic moment was taken to be from 2.4×10^{22} to 5×10^{22} cm^3 (refs 5–7). For Venus we have taken a core density equal to that of the Earth and a fractional radius within 10% of that of the Earth. The magnetic moment has been taken to be less than 1×10^{22} G cm^3 (ref. 8). For the Earth we have taken a moment of 8×10^{25} G cm^3, a radius of 3,486 km, and a density of 11 g cm^{-3} (ref. 9). For Mars, we have taken a range of models with realistic core densities given by Okal and Anderson[10] for the internal structure and the magnetic moment of Dolginov and coworkers[11] as an upper limit[12]. For Jupiter we use the models of Stevenson and Salpeter and its stated uncertainties[13] and the moment of Davis and Smith[14].

The straight line through the Earth has a slope of unity. We would expect that those planets with operating dynamos would fall on this line. Clearly Jupiter and Mercury do not. However, they both fall on a slightly displaced line with unit slope. Thus relative to Jupiter and Mercury the Earth seems to be anomalously high. It might be said that since the three planets with clearly established dynamos do not fall on one line, then the scaling law has failed. However, for the sake of further discussion, we will assume that the scaling law works but that the Earth is anomalous.

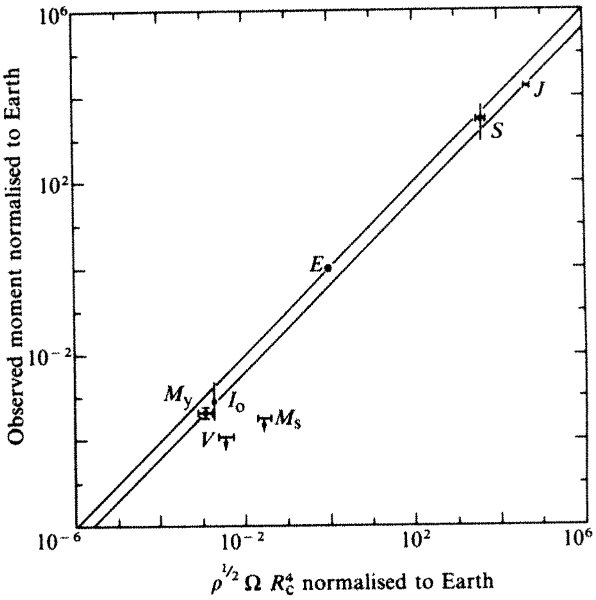

Fig. 1 Application of the scaling law to Earth (E); Mars (M_s); venus (V); Mercury (M_y); Saturn (S); Jupiter (J) and Io.

Venus and Mars do not lie near either line which suggests that they do not have dynamos at present. If one were to detect unambiguously an intrinsic field at Venus or Mars due to an internal dynamo at or below these limits, this observation would necessitate reassessment of Busse's dynamo theory.

For Saturn we have taken Slattery's model[15] and arbitrarily assumed ±6% for the uncertainty in core radius. The dot marks the moment inferred from radio observations[16]. This data point falls squarely between the jovian and terrestrial scaling lines. If we assume that the jovian scaling line is the proper scaling line with which to compare Saturn we would predict a core radius for Saturn of 33,000 km, much greater than the 28,000 km assumed by Slattery. If the modelling is correct, then the expected moment is 1.2×10^{29} G cm^3 corresponding to an equatorial surface field of 0.5 G. While it is difficult to judge which is the more accurate, the theoretical modelling of Saturn's interior or the scaling of the radioemissions, we argue that as the source of the radioemissions is not understood for the Earth, Jupiter or Saturn, the modelling effort is more accurate at present. Thus, our first prediction is that Pioneer 11 will measure a moment of about 1.2×10^{29} G cm^3. If the jovian modelling efforts can be of any guide we expect this estimate to be correct to about ±20%.

Finally let us examine Io. A prediction for Io has already been made by Neubauer[17]. He assumes an Fe–FeS eutectic core with a density of 5.3 g cm^{-3} and a core radius of 890 km corresponding to an average chondritic composition. Voyager pictures of Io show many active volcanoes suggesting that Io is molten internally. This in turn suggests Io has in fact differentiated and formed an iron core. Thus far the Voyager mission has not provided further constraints on the size of the core. However, it is clear that the satellite is losing sulphur. Thus we will also use a higher core density, 7 gm cm^{-3} (ref. 10) in our estimates of the expected moment. This expectation is indicated by the vertical line which crosses the Earth scaling law at a moment of 1.3×10^{23} G cm^3, very close to Neubauer's prediction. The line crosses the Jupiter–Mercury line at 6.5×10^{22} G cm^3. This same moment has been inferred from observations of Io's ionosphere and effects on particle motions by Kivelson and coworkers[18]. Our second prediction, based on the adoption of the Jupiter–Mercury line as the best scaling line, is that Io has a moment of

0028-0836/79/420552—02$01.00

close to 6.5×10^{22} G cm^3. The weak link in this prediction is the choice for the size of the core of Io.

If the above predictions are correct, we must seek an explanation for why the Earth's field is anomalously high, as the scaling law does not involve the strength of the energy source. Perhaps the answer lies in the precessional torques applied to the Earth's core by the Moon.

I thank D. J. Stevenson and S. K. Runcorn for helpful discussions.

Note added in proof: On 1 September 1979, Pioneer 11 flew by Saturn and detected a magnetic moment of 4.8×10^{28} G cm^3 (E. J. Smith, personal communication). To be consistent with the Busse scaling law, the conducting core of Saturn would have to be 23,000 km in radius. Unless future analysis of the Pioneer 11 gravity data and a reassessment of the models of the interior structure are consistent with such a small core we must conclude that Busse's scaling law is useful for predicting planetary moments only to within a factor of about 2.5.

Isotope effects and correlated motion in self and sodium ion diffusion in water

L. W. Barr & M. A. M. I. Elmessiery

Paisley College of Technology, Paisley, Scotland, UK

The information gained on atomic motions in solids from studies of the isotope effect in diffusion[1,2] prompted us to examine this effect in liquids, in particular for diffusion in water, because of its importance as a solvent. As isotope effect measurements for self-diffusion in water and deuterium oxide are available[3], the isotope effect for ^{22}Na and ^{24}Na ions in water was studied. We describe here a new technique which applies to liquids the solid state technique of simultaneous diffusion[4] of these isotopes followed by sectioning and half-life (or other suitable method) separation.

A dilute sodium chloride solution (0.034 mol l^{-1}) was gelled by the addition of between 1 and 3% agar (Ion Agar No. 2) and cast into a tube from which it could be pushed by an accurate screw thread and plunger for sectioning into slices 1–3 mm thick. Suitable quantities of ^{22}NaCl (carrier free ^{22}Na, Radiochemical Centre, Amersham) and ^{24}NaCl (prepared by irradiation of NaCl in the Scottish Universities Research Reactor) in aqueous solution were dripped onto a freshly cut gel surface from a hypodermic syringe before the tube was capped for annealing in a temperature controlled bath.

After sectioning, the gel slices were weighed and centrifuged down into suitable counting tubes to provide a reproducible counting geometry and each counted repeatedly in a well-type NaI scintillation counter until the 15-h half life ^{24}Na had completely decayed. From the decay curve for each section the specific activities C_{22} and C_{24} for each tracer could be calculated.

Plots of the log of the specific activity against the square of the penetration distance were accurately linear over a two decade range in activity, as required by the appropriate solution of Fick's equation. Moreover, comparison of the resulting diffusion coefficients with those obtained by conventional methods showed that the sodium diffusion was taking place through the water phase.

The isotope effect was then calculated from the equation[16]

$$\ln (C_{22}/C_{24}) = \text{constant} - (D_{22}/D_{24} - 1) \ln (C_{22})$$

The results obtained for the isotope effect for sodium diffusion in water are listed in Table 1 together with the self-diffusion results of Mills[3] and one value for ^{6}Li and ^{7}Li calculated from the limiting conductance data of Kunze and Fuoss[5].

The results were analysed using Schoen's equation[6]

$$\left(\frac{D_\alpha}{D_\beta} - 1\right) = f \, \Delta K \left[\left(\frac{m_\beta + nm_0}{m_\alpha + nm_0}\right)^{1/2} - 1\right] \qquad (1)$$

where D_α/D_β is the ratio of the diffusion coefficients of the two isotopes in the same solvent, f is the correlation factor for the diffusion process, m_α and m_β are the masses of the isotopic tracers and n and m_0 the number and average mass of any non-tracer molecules involved in the diffusion movement. In solids ΔK is the fraction, possessed by the diffusing species, of the total translational kinetic energy associated with the decomposition of the saddle point configuration[1]. Clearly $0 \leq \Delta K \leq 1$ and in many metals, particularly the close packed metals[2], ΔK is close to unity.

Although Schoen's equation is exact only in certain conditions[1,7], it has been applied to glass[8] and benzene[9] where the required symmetry conditions would not be met. Water has a structure which, at least over short distances, approximates to a tetrahedral arrangement of water molecules[10–13] with Z, the coordination number, lying between 4.4 and 5.5. For such a molecular arrangement equation (1) should hold at least to the precision justified by the experimental data.

Table 1 shows values of $f\Delta K$ calculated from equation (1). For water $n = 0$, while for sodium and lithium m_0 is the mass of a water molecule and a value of $n = 4.5$ was used in view of the known hydration of alkali ions in water. If the hydration number is defined as the number of water molecules which have surrendered their own translational freedom and remain with the ion when it moves relative to the surrounding water, then recent reviews[14,15] suggest that the most probable integral value for n is 4 ± 1 for sodium and 5 ± 1 for lithium. The value of $n = 4.5$ chosen is then a very convenient test value for both ions: it is probably close to the best possible estimate for sodium[15] but may be slightly low for lithium.

It is encouraging that the values of $f\Delta K$ so calculated for water and the hydrated alkali ions are so similar. This is particularly true for the alkali ions since in that case the experimental techniques used were so different.

It has been shown elsewhere [1,16] that the correlation factor f_0 for self-diffusion by a vacancy or hole mechanism can be approximated with a fair degree of accuracy by

$$f_0 = 1 - \frac{2}{Z} \qquad (2)$$

where Z is the coordination number. This is very important when applying the idea of correlated motion to liquids since long-range order can be neglected and attention focussed on the number of neighbours in the first coordination shell.

The striking agreement between the experimental $f\Delta K$ for water and the range of values of f_0 calculated from equation (2) supports a hole mechanism for diffusion in water and suggests that ΔK is close to unity, $f_0 \simeq 0.62$ and Z is about 5 (ref. 12). Note that a ΔK of 1 implies that the frequency with which a tracer moves into a hole is inversely proportional to the square root of its mass and this is in line with theoretical predictions[17].

0028–0836/79/420553—03$01.00

Note that molecular motion in water may be strongly correlated. Indeed, as

$$D\ (\text{measured}) = D(\text{random})\, f_0$$

the observed diffusion coefficient may be about 40% less than would be calculated on the basis of random motion. This accords with predictions made on the basis of molecular dynamics[18]. This interpretation differs from that of Dunlop[19] who suggested that $f_0 = 1$ and $\Delta K \simeq 0.5$.

For sodium and lithium also ΔK can be assumed to be close to one. For sodium f would be expected to exceed that for water diffusion as it is a slow diffusing impurity.

The results shown in Table 1 can be interpreted on the basis of a crude model. Suppose each alkali ion is surrounded symmetrically by between 4 and 6 hydrated water molecules[20], the whole loosely contained in a cage of free water. On average the hydrated water will have fewer free molecules adjacent to it than a free molecule because of the presence of the sodium ion and the remainder of its hydration cell on one side. If a complete hemisphere were forbidden then each hydrated water molecule would have on average 2.5 free molecules adjacent to it. If we assume an integer value of 3 for the average then each hydrated water with its three free water molecules and the alkali ion forms a structure having a coordination number of four.

Suppose that a space occurs in the shell of free water adjacent to a hydrated water molecule. That hydrated molecule can then move into the space carrying with it the hydrated ion. This produces a space next to the free molecules on the opposite side of the hydrated ion. One of these free molecules could move to occupy the space or alternatively the hydrated alkali ion could move back to occupy its original position.

This motion of hydrated alkali ions and free molecules closely resembles an impurity molecule diffusing on a diamond lattice for which an expression for f is available[1]. If the relative probabilities of a hydrated or free water molecule moving into a space are described in terms of jump frequencies ω and ω_0 then the correlation factor for hydrated alkali ion motion in such a structure is

$$f = \frac{\omega_0}{\omega + \omega_0} \tag{3}$$

which for the case of self-diffusion where $\omega = \omega_0$, reduces to $f = 0.5$ as required by equation (2). If $\omega_0 > \omega$ then $f > f_0$.

If we assume that the probability of a hole forming in the shell adjacent to a hydrated ion is the same as in pure water then, as the mean distance moved in each step is the same for free or hydrated water, the ratio of the coefficients of self and impurity diffusion can be written as

$$\frac{D(H_2O)}{D(\text{ion})} = \frac{\omega_0 f_0}{\omega f} \tag{4}$$

This assumption is plausible as both sodium and lithium are 'structure-forming' ions, known not to perturb the structure of water. In the case of lithium, molecular dynamical calculations also suggest that the Li^+ ion causes relatively little disturbance of the structure of the surrounding water[20]. Note that this assumption cannot be extended to other ions. For example, the addition of caesium ions to water enhances water self-diffusion[21], probably because of a greater ease of formation of holes adjacent to the caesium ion.

Table 1 Isotope effects and correlation factors for self and impurity diffusion in water

System	Temperature (°C)	$(D_\alpha/D_\beta - 1)$	$f\Delta K$	f_0 (Theory)
HDO/HTO	1	0.0135	0.52	
in	5	0.0181	0.69	0.55

	45	0.0167	0.64	0.64
	Average	0.0161	0.62	
HDO/DTO	5	0.0330	0.64	
in	15	0.0287	0.56	0.55
D_2O	25	0.0299	0.58	to
	Average	0.0305	0.59	0.64
$^{22}Na/^{24}Na$	19	0.0059		
in	19	0.0065		
H_2O	19	0.0056		
	30	0.0066	0.63 ± 0.03	
	39	0.0057		
	50	0.0062		
	Average	0.0061		
$^6Li/^7Li$ in H_2O	25	0.0035	0.61	

Table 2 Correlation factors and hydration numbers for alkali diffusion in water at 25°C

System	Observed ratio	Calculated ratio	f	n	ω_0/ω
$\frac{D(H_2O)}{D(Na)}$	$\frac{2.236}{1.296} = 1.72$	1.68	0.64	4.6	1.8
$\frac{D(H_2O)}{D(Li)}$	$\frac{2.236}{1.030} = 2.17$	1.59	0.71	5.3	2.5

The units of D are $10^{-5}\ cm^2\ s^{-1}$. The values of the tracer diffusion coefficients of water and sodium are from refs 3 and 22. The value for lithium was calculated from the limiting conductance, ref. 23.

Eliminating ω_0/ω from equations (3) and (4) yields the simple relationships

$$\frac{D(H_2O)}{D(\text{ion})} = \frac{f_0}{1-f} \tag{5}$$

and

$$\frac{\omega_0}{\omega} = \frac{f}{1-f} \tag{6}$$

for this two frequency model.

Table 2 gives experimental values for the left-hand side of equation (5) at 25°C for sodium and lithium together with calculated values using the f and f_0 values from Table 1. The agreement is surprisingly good, particularly for sodium, considering the crudeness of the model and the assumptions made.

An alternative application of equation (5) is to use the experimental values of $D(H_2O)/D(\text{ion})$ and f_0 to calculate f and then, using the experimental values for the isotope effect and Schoen's equation, (1), to calculate independently values of the hydration number, The resulting values of f, and n are shown in Table 2.

The values of n so obtained are in excellent agreement with those obtained by other methods and support the conclusion that the hydration number for lithium slightly exceeds that for sodium.

Finally, values of ω_0/ω calculated using the f values from Table 2 are also listed. In the case of lithium this ratio is almost equal to the inverse square root of the masses of the hydrated ion and water.

We thank the SRC for a capital grant. L.W.B. thanks the Australian National University for the award of a visiting Fellowship, and we are grateful to Drs R. Mills, L. Woolf, and Professor R. H. Stokes for helpful discussions.

Solar bacterial biomass bypasses efficiency limits of photosynthesis

Helmut Tributsch*

Fritz-Haber-Institut der Max-Planck-Gesellschaft, D-1000 Berlin 33, Faradayweg 4-6, FRG

A new kind of solar energy technology is proposed here which will allow biomass to be produced at efficiencies higher than the theoretcial limits of photosynthesis and at one order of magnitude higher than by present processes. Its principle is to produce the chemically simple inorganic energy source of certain autotrophic bacteria by solar thermal, photoelectrochemical or solar powered electrochemical methods and to grow these bacteria, for example *Thiobacillus ferrooxidans*, which can live from the oxidation of ferrous to ferric iron in continuous cultures in the dark. A remarkable prospect of this novel strategy for gathering solar energy would be that biomass for food, fuels and materials could be produced in largely automatic and compact factory-type installations on arid and infertile land, to which the limited amount of water which is needed to fix CO_2 and is extracted in the form of dry organic products may be transported as a raw material.

The efficiency limits of photosynthesis are well known. Insufficient photon energy and incomplete utilisation of photon energy reduce the upper theoretical limits of the conversion efficiency to approximately 11% of the total solar radiation on Earth. Inevitable nongenerative losses and plant system losses (such as reflection, and metabolic conversions) further reduce the maximum practical conversion efficiency to 5–6%[1]. High daily yields approaching this maximum have been reported, but even very productive tropical grasses such as sugar cane do not yield crops at efficiencies of more than 0.6% on an annual basis[2]. The water hyacinth, which is considered to be one of the most efficient solar energy converters is expected to be capable of yields of 45–60 tonnes acre^{-1}, corresponding to ~3–4% efficiency under careful management[1]. Unfortunately, the need for fertile soil and abundant sweet water restricts biomass production mostly to regions which to a large extent are already cultivated. It cannot be extended to the huge unused desert regions of the world where solar energy is at its most intense.

The rather low efficiency limits of biomass production and the high loss of water which is primarily due to evaporation from the plants and the soil can be overcome by the proposed biomass technology. This could replace the inefficient multi-photon biological mechanism of conversion of solar energy into energy-rich primary products by more efficient artificial solar techniques, which could provide either concentrated solar heat or solar electricity for the production of chemically simple inorganic energy carriers on which microorganisms feed.

I have cultivated and studied the bacterium *T. ferrooxidans* for several years[3], and to demonstrate the feasibility of such a solar technology I have theoretically investigated a biomass installation, in which this bacterium is grown on ferrous iron produced from ferric iron by a solar thermal method. In analogy to the generation of hydrogen and oxygen from water by thermal processes many chemical cycles can be proposed which evolve oxygen from water and reduce ferric ions instead of protons. The estimated efficiencies of proposed thermal processes to generate H_2 and O_2 from water range from 30 to 50% (refs 4–7) and will not be lower for the production of ferrous iron, which has a considerably more positive redox potential than that of hydrogen. While no practicable thermochemical processes with less than three steps are known for the production of H_2 and O_2 from water, two-step processes are possible for the generation of ferrous iron and oxygen. An example are the reactions:

$$\begin{aligned} 2\,\mathrm{FeCl_3} &\xrightarrow{350\,^{\circ}\mathrm{C}} 2\,\mathrm{FeCl_2} + \mathrm{Cl_2} \\ \mathrm{H_2O} + \mathrm{Cl_2} &\xrightarrow{700\,^{\circ}\mathrm{C}} 2\,\mathrm{HCl} + \tfrac{1}{2}\mathrm{O_2} \end{aligned} \tag{1}$$

T. ferrooxidans requires an acid environment ($pH = 1.2$–4.5) and obtains its energy for growth from oxidising ferrous iron, metal sulphides, sulphur or soluble inorganic sulphur compounds. It grows in strictly autotrophic conditions (optimum at 35 °C), obtaining all the carbon required for biosynthesis from atmospheric carbon dioxide which it fixes by biochemical mechanisms that are part of or related to the Calvin cycle[8]. Ammonium is a suitable source of nitrogen, but evidence for the ability of *T. ferrooxidans* to fix atmospheric N_2 has been presented[9]. The bacterium develops a very high tolerance for metal ions. Cl^- retards Fe^{2+} oxidation at concentrations above $6\,\mathrm{g\,l^{-1}}$, but tolerance to cultivation in hydrochloric acid can be developed and its growth on iron in a medium where all iron is supplied as the chloride is possible provided some additional sulphate is available[10]. *Thiobacillus ferrooxidans* can therefore be cultivated on $FeCl_2$ supplied by the solar thermal process (1) and thereby recycles $FeCl_3$ and water:

$$2\,\mathrm{FeCl_2} + 2\,\mathrm{HCl} + \tfrac{1}{2}\mathrm{O_2} \longrightarrow 2\,\mathrm{FeCl_3} + \mathrm{H_2O} \tag{2}$$

T. ferrooxidans accomplishes the oxidation of Fe^{2+} at rates 10^5–10^6 times faster than the rates of inorganic oxidation at the corresponding pH (ref. 8). The energy which it thereby gains depends on the pH and ranges from $7.84\,\mathrm{kcal\,mol^{-1}}$ (pH 1.5) to $5.89\,\mathrm{kcal\,mol^{-1}}$ (pH 3). For the reduction of CO_2 to the level of carbohydrate approximately $118\,\mathrm{kcal\,mol^{-1}\,CO_2}$ are needed. For an output of $7\,\mathrm{kcal\,mol^{-1}\,Fe^{2+}}$ about $16\,\mathrm{g\,mol^{-1}\,Fe^{2+}}$ would be consumed to fix $1\,\mathrm{g\,mol^{-1}\,CO_2}$. Per gram mol Fe^{2+} (56 g) a maximal theoretical cell yield of approximately 1.4 g dry weight could therefore be expected[8]. The energy conversion efficiencies actually obtained by *T. ferrooxidans* grown on ferrous iron have steadily improved with the development of improved strains and the use of continuous flow chemostat cultures. A detailed recent analysis of growth yields and total energy balance at pH 1.6 is given by Kelly *et al.*[11], which suggests that $19\,Fe^{2+}$ ions are oxidised per CO_2 molecule fixed. The true growth yield Y_G (g dry weight per atom Fe^{2+}, if no substrate were used for the maintenance of the bacteria) was found to be 1.33, corresponding to an energy conversion efficiency of 78.8%. The yield actually obtained, which includes the energy losses due to cellular processes and is subject to non-competitive and competitive product inhibition by the ferric iron, varied depending on the condition of cultivation between 0.156 and 0.8 g dry weight per g atom Fe^{2+} (ref. 11). A dry weight yield of 0.5 g per g atom Fe^{2+} corresponding to an efficiency of 35% on a free energy basis has also been reported[8,12] and I believe that is a reasonably achievable value for large scale technical biomass production by *T. ferrooxidans* in continuous culture.

If this efficiency ($\eta_2 = 35\%$) is combined with the efficiency for the solar thermal generation of ferrous iron ($\eta = 30$–50%) a total solar energy efficiency for biomass production of $\eta =$

---

0028-0836/79/420555—02$01.00

$\eta_1\eta_2 = 10.5\text{–}17.5\%$ is obtained for the proposed solar technology. On an annual basis it would thus be 17.5 to nearly 30 times higher than the biomass yield from a sugar cane field of comparable area. The bacterial biomass would be very protein-rich (*T. ferrooxidans* contains 44% protein, 26% lipid, 15% carbohydrate and at least two B-vitamins[13]), has no known negative physiological effect and could be collected in installations of moderate size, since *T. ferrooxidans* can be cultivated on high concentrations of ferrous iron, achieving growth rates exceeding 0.2 h^{-1} and doubling times <3.5 h in continuous flow cultures[14]. Using published experimental data[11] biomass yields of 70 kg dry wt m^{-3} yr^{-1} can already be estimated for continuous cultures in their present stage of development. Single cell protein factories have already been shown to be feasible in the case of petroleum conversion, and problems arising from the processing of the material for specialised use seem to be solvable.

What would a solar bacterial biomass (SBB) plant look like? Built as a solar tower installation with a collector field of 1 km radius in a desert it would cover an area of 3.14 km^2. As not all the incident sunlight could be collected in the central receiver the input of solar energy would approximately correspond to that of a comparable sugar cane field in a tropical region with inferior insulation. However, up to 30 times more biomass could theoretically be extracted from the SBB installation which could be built on infertile soil. The thermochemical reactions (1) and the energy supplying reaction (2) on which bacterial biomass is grown recycle the water needed to cultivate *T. ferrooxidans* and the only real loss of water is due to the biological fixation of CO_2. If biomass is extracted from the SBB plant as dry material the weight equivalent of water which would have to be replaced would be smaller or—if some losses are taken into account—of a similar order of magnitude. Provided that the water in the SBB installation is periodically cleaned, which could occur during the thermochemical step (1), all that may be needed is that those transportation vehicles which carry away dry biomass also supply water to the plant. The total amount of water needed to operate a SBB plant would fill tanks (10 m high) which cover <10% of the collector area (mirrors can be placed on top of these). The addition of a fertiliser to the culture medium will be necessary but the bacteria's apparent ability to utilise nitrogen from the air[9] could be developed. (A standard culture medium has been described in ref. 15).

The described energy collecting cycle for a SBB installation based on *T. ferrooxidans* and a solar thermal process is just one technical possibility which is especially interesting since it promises high theoretical efficiencies. One disadvantage, which is common to all thermochemical cycles, is that relatively large quantities of material (Fe^{2+}, Fe^{3+}) would have to be circulated to maintain a relatively small flow of energy. The simplicity of the reactions involved (1)(2), and a skilful technical design (for example, utilisation of thermal convection) might keep such additional energy losses within reasonable limits. They would not occur if the solar thermal process for the generation of Fe^{2+} were replaced by a solar powered electrochemical one (current generation by solar cells, ocean thermal gradient, wind, wave power) or a photoelectrochemical one in which ferrous iron is produced in the cathodic reaction and oxygen in the anodic reaction of an electrochemical cell. In this case the bacteria could in principle be grown in the same reactor in which their energy source is produced and they would be converting irregularly supplied electrical energy into valuable organic products. The total efficiency ($\eta = \eta_1\eta_2$) which would seem to be feasible in this case is of the order of 6%. The same bacterium *T. ferrooxidans* could also be cultivated on sulphur, thiosulphate, many metal sulphides or a combination of metal sulphides with ferric iron provided the energy supplying inorganic substances can be efficiently recycled from the oxidation product sulphate by a solar thermal or solar electrochemical process. *Thiobacillus thiooxidans* could be grown on sulphur or inorganic sulphur compounds and *Knallgasbacteria* on solar hydrogen. There are other bacterial species which feed on energy sources which are chemically sufficiently simple to be synthesised by solar technological methods.

The suggested SBB technology is based on established principles and does not involve expensive raw materials. It also seems that certain practical problems which will arise (for example, the separation of bacterial biomass from ferric iron) could be handled with appropriate applied research. These preconditions, the promise of biomass yields, which are one order of magnitude higher than that from present day agriculture, extreme economy of water utilisation and the prospect of compact and largely automatic installation make this a practical proposition. However, SBB installations will only become commercially interesting after large-scale solar plants have proved to be feasible. A SBB technology would seem to be rewarding since the combination of modern solar technology with inorganic bacterial oxidation would break down some of the restricting environmental conditions imposed on the solar synthesis of biological products and enlarge the surface area of the world suitable for production of food, energy and materials.

Amino acid ratios and the correlation of raised beach deposits in south-west England and Wales

J. T. Andrews

D. Q. Bowen & C. Kidson

Department of Geography, University College of Wales, Aberystwyth, UK

Interest in studies of amino acid racemisation as a framework for Quaternary chronostratigraphy has increased recently[1–4]. These studies have used different materials, but the main two substances have been bone and shell. Different shell genera can have different rates of racemisation[5], so the use of new genera requires some study of the kinetics of the reactions before the results from one taxa can be compared to another. We report here the successful application of amino acid racemisation studies on the limpet *Patella vulgata* as a basis for correlating the scattered raised marine beaches of interglacial age(s) from south-west England and Wales. We show that the epimerisation of D alloleucene: L isoleucene (D allo: L iso) in *P. vulgata*, provides a useful basis for regional correlation. This mollusc lives attached to rocks above the mean tide level and, hence, spends a good portion of its life living at the ambient air temperature. We suggest that the fossil material may have been primarily exposed to regional atmospheric climate since death, because all available evidence points to sea level being lower than present during much of the past 120,000 yr (ref. 6).

Table 1 Amino acid ratios on *Patella vulgata* (*Pv*) and *Macoma balthica* (*Mb*) from sites in south-west UK

Sites are shown in Fig. 1 and the data are plotted in Fig. 2.

* No. in sample, when >3 this figure includes reruns.

† Five valves including one radically different ratio, for which three reruns are given in parentheses.

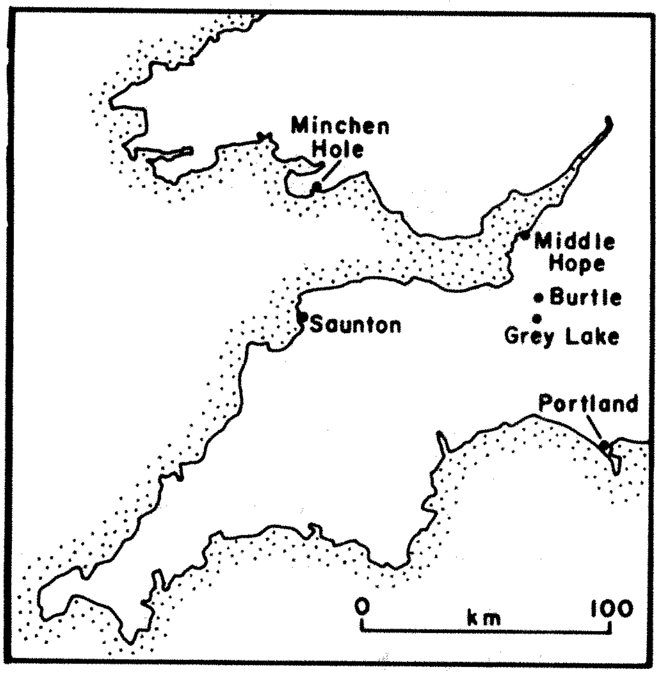

Fig. 1 Sites of interglacial raised marine beaches.

Three shells were prepared from each site (Fig. 1; Table 1). The shells were first cleaned in 2M HCl, and the cleaned fragments dissolved in 8M HCl. Half the aliquot was then dried under vacuum and rehydrated with a solution of *p*H 2 containing a 'spike' of the inorganic amino acid, norleucene. This spike provided an internal calibration. The other half was heated in a controlled oven at a temperature of 110 °C for 22 h. It is then dried and rehydrated. These two preparations provided a measure of the free amino acids (those released by a natural diagenesis) and combined amino acids (free plus peptide-bound). The sample was then placed on an ion-exchange amino acid analyser. For most age dating purposes, we relied on the free and combined ratios of D allo: L iso to indicate the relative age of a sample[1,2]. In addition, we performed pyrolyosis experiments on modern shells of *P. vulgata*. Cleaned shell fragments were heated at 144 °C in the presence of 1 ml purified water. At selected times, the samples were removed from the oven, prepared and analysed (Table 2). The results can be compared to similar experiments on valves of *Hiatella arctica*. A feature of the reaction of *P. vulgata* to the heating experiments is the rapid approach of the free fraction to equilibrium (D allo: L iso = 1.35) and the slow epimerisation of the combined D allo: L iso ratio.

A total of eight shell collections have been processed (Table 1; Fig. 2). They consisted of: a modern valve of *P. vulgata* (AA1-767), two samples of Holocene age from Scotland and south-west England, and five collections from some of the classic raised marine beaches of the region (Fig. 1)[7,8]. The modern shells show no free amino acids and the D allo: L iso for the combined amino acids varies between 0.007 and 0.02. This ratio is caused by the actual processing of the samples. The modern ratios are significantly different from those obtained from Holocene shells (Table 1) where the D allo : L iso (free) averaged 0.35 and 0.44 and 0.04 and 0.032 (combined) respectively.

Four of the five samples from the raised beaches of south-west England and Wales (Fig. 1; Table 1) fall into two groups with D allo : L iso (combined) ratios of 0.10 and 0.12 (Fig. 2). Repeat analyses of the same preparation (=shell) gave precisions of

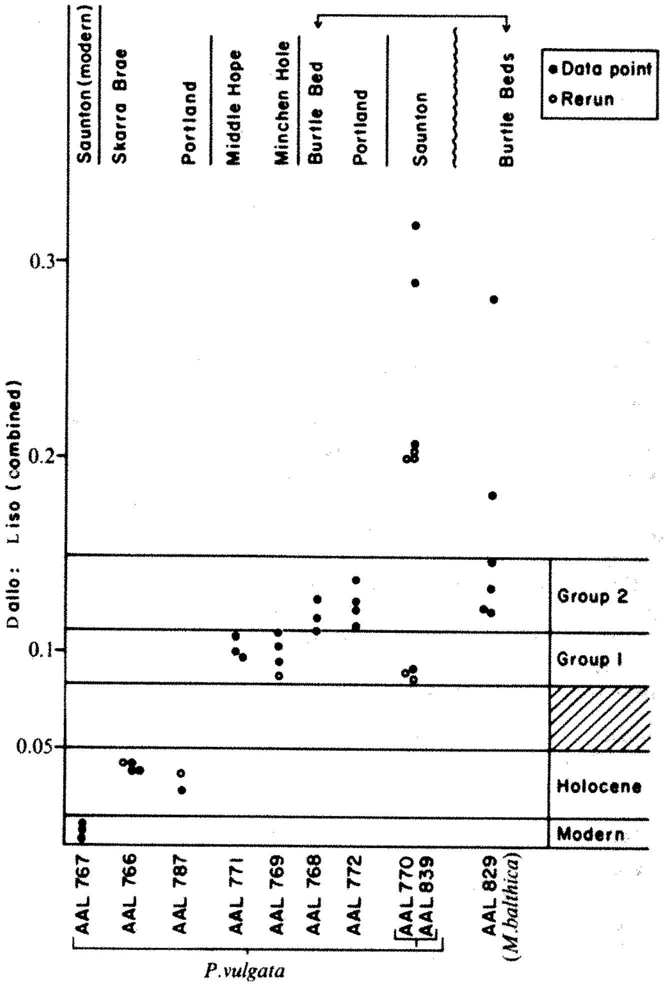

Fig. 2 D allo : L iso ratios for combined amino acids on *P. vulgata* and *M. balthica* from sites in the south-west UK. Data from Table 1.

±5%—smaller than the usual variability between shells from a single stratum (5% to 18%). Analysis of variance (one-way) on the combined D allo : L iso ratios indicates that we can reject the null hypothesis (95% confidence level) that the four samples come from a single population ($F = 8.37$, d.f. 3, 8). The free D allo : L iso ratios (Table 1) do not show an exactly similar pattern and are not considered as reliable an index of relative age as the combined ratio[10,11].

The Saunton raised beach site is not so straightforward in the interpretation of the amino acid ratios. Four out of the five shells gave combined ratios averaging 0.26 ± 0.066 which indicates either (1) that higher environmental temperatures affected these shells since death, or (2) the shells are distinctly older than the same species from the other four sites. The fact that one shell gave a typical value for the other raised marine beaches of 0.1 (combined) may indicate that the beach is the product of two distinct high (interglacial) sea levels, a possibility indicated on stratigraphic sources at Minchin Hole Cove, Gower[7], or that contamination has affected some valves. It is difficult to invoke an explanation for the higher ratios that involves some local temperature perturbation; thus, we favour the second explanation while admitting that more research is required on shell assemblages from the Saunton site. The Portland raised beach and the Burtle Bed samples show somewhat higher combined D allo : L iso ratios than the two other beaches of supposed last interglacial age, taken as equivalent to oxygen isotope stage 5e (ref. 9). It is not yet clear whether the difference reflects a real difference in age or is related to environmental conditions at these sites.

Five valves of *Macoma balthica* were also run from the Burtle Beds (Greylake no. 2). One valve had a cement residue after cleaning and gave a combined D allo : L iso ratio of 0.282. The remaining four valves produced a tight cluster of ratios averaging 0.14 ± 0.025 (Table 1).

Amino acid ratios D allo : L iso for the combined fraction indicate that shells of *P. vulgata* collected from five interglacial sites are either not of the same age, or they have been affected by different temperatures or diagenetic histories since the death of the shells. The Saunton raised beach is clearly the oldest (or most contaminated), although one of the five shells analysed had a ratio similar to those from the Middle Hope and Minchin Hole raised beaches (Fig. 2). These last mentioned sites have ratios somewhat smaller than those determined from the Portland and the Burtle Bed sites. A preliminary conclusion is that the amino acid data suggests the presence in the south-west UK of raised beaches of either two or three different ages. The Portland beach has been regarded as marginally older on altimetric grounds[12]. We cannot yet determine whether these represent sea level highs during whole or part of marine isotope stage 5, or part of that 'interglacial' and an earlier interglacial in the case of the Saunton data (Fig. 2). An alternative explanation of our Saunton data is that the majority of the shells are contaminated and that the age of the beach is given by the ratios of 0.09 (Fig. 2).

Correlation between our sites and those reported by colleagues from south and east England[11] is made difficult because of the absence of *Patella vulgata* in those sites and because our sites generally lack *Corbicula fluminalis*, the species used most extensively in their study. Our *Macoma balthica* ratios, however, provide a start to such a correlation programme. Results from assays of *Macoma* spp. from the crag deposits of East Anglia[11] (Table 3) show significant differences from our findings. The closest site between our data and that of Miller *et al.*[11] is at Selsey, southern England, where a single *M. balthica* gave a combined ratio of 0.33. This ratio is much greater than our results (Table 1), although we note that one sample from our collection which could not be cleaned fully gave a comparable ratio to the *M. balthica* from Selsey. We reject our ratio, however, because we judge it to be contaminated and conclude that the Burtle Beds (Greylake 2) site is characterised by *M. balthica* ratios (combined) of 0.14 ± 0.025.

Table 2 Results of heating *Patella vulgata* at 144 °C

Hours heated	Free (D allo : L iso)	Combined (D allo : L iso)
Control (0 h)	—	0.015
20	0.88 (0.66)*	0.194 (0.292)

Abrupt end of the last interglacial s.s. in north-east France

Geneviève Woillard

Chargé de Recherches du Fonds National Belge de la Recherche Scientifique, Institut Botanique, Laboratoire de Palynologie et Phytosociologie, Université Catholique de Louvain, Place Croix-du-Sud 4, 1348 Louvain-la-Neuve, Belgium

Close study of past interglacials might indicate how and when the present interglacial will end and whether we are heading towards a warming or a cooling[1,2]. No certain prediction has been possible because of man's interference with the environment. But, we report here that when exploring the records of past temperate intervals, we observed frequent signs of abrupt changes of local environment. In particular, abrupt shifts in forest composition end each Pleistocene interglacial whose record was studied in detail. In Grande Pile (north-east France), the Eemian (s.s.) (oxygen isotope substage 5e) temperate forest was replaced by a pine–spruce–birch taiga within ~150 ± 75 yr. These results are based on rich pollen content of continuously deposited laminated gyttja and on the assumption of a constant sedimentation rate during the last 11,000-yr long interglacial. If the area today was affected in a similar way, the relatively fast transition of the environment, and by implication of the climate, would place serious constraints on man.

The continuous pollen-rich deposit from the Grande Pile lake gyttja and peat bog, in southern Vosges (north-east France), is very suitable for this kind of study[3–6]. It covers the interval from 140,000 yr BP to the present, and includes the last interglacial,

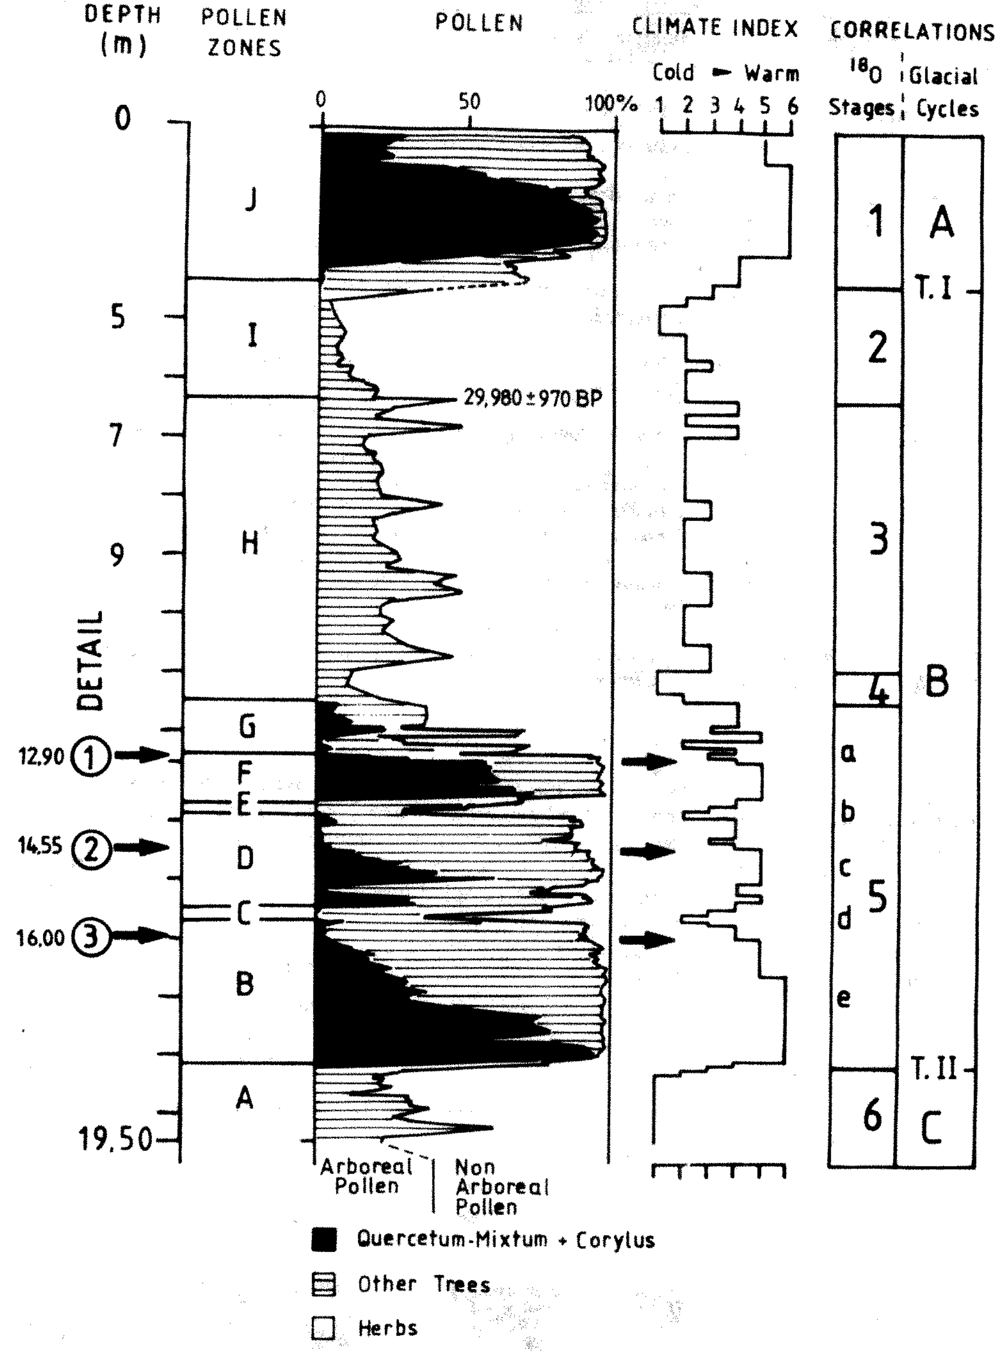

Fig. 1 Grande Pile palynological sequence from the present to 140,000 yr BP. Simplified figure after G.W.[5,6]: general pollen sequence established with the three cores I, XIV and X; zones A to G from the core X. Between 200 to 500 pollen grains counted at 277 levels; percentages based on total sum. Climate index based on variations in pollen assemblage: 1, tundra; 2, shrub-tundra; 3, open taiga; 4, dense taiga; 5, mixed hardwood–coniferous forest; 6, hardwood forest. ^{18}O Stages after Emiliani[27,28] and Shackleton[29,30]; glacial cycles after Kukla[31] and Ruddiman and McIntyre[32]; T. I. (Termination I) and T.II (Termination II) after Broecker and van Donk[33]. 29,980 ± 970 yr BP is the ^{14}C date Lv. 748. Arrows ①, ②, ③ indicate abrupt climatic changes shown in detail in Figs 2 and 3.

the last glacial and the Holocene (Fig. 1). The climatostratigraphic information is directly comparable to that obtained in northern Greece[7,8] and in oceanic records[4,5,9]. Three forest episodes (Fig. 1, zones B, D, F) probably correlate with the oxygen isotope stage 5 (Fig. 1). But, only the lowermost one indicates a climate as warm as the present, and can be correlated with typical pollen profiles of the Eemian, as defined in its type area[10]; it is the equivalent of oxygen isotope substage 5e peaking at 125,000 yr BP.

The deposit is finely laminated, so there is no doubt about the continuity of deposition and about the complete lack of post-depositional disturbance.

An abrupt change of vegetational assemblage is observed to end each of the three forest episodes (Fig. 1, arrows 1, 2, 3): all the temperate species retreat, and are even eliminated by a sudden expansion of boreal trees (Fig. 2). A rapid rise of *Pinus*, followed by *Betula* and *Picea*, ends the *Quercus–Carpinus–Corylus* phase of the upper interval (Fig. 2*a*), the *Quercus–Carpinus* phase of the median one (Fig. 2*b*), and the *Abies–Picea–Carpinus* phase of the lowermost one (Fig. 2*c*). A comparatively abrupt change in vegetation is observed in pollen diagrams from elsewhere, ending past interglacials[7,10–19].

As shown at Grande Pile[5,6], the Eemian is one of the previous interglacials most resembling the Holocene (climate index in Fig. 1, zones B and J; description in Table 1). The transition from the late-temperate zone to the post-temperate zone[20] (Table 1) within the Eemian is rarely demonstrated in terrestrial records because it represents the end of an interglacial. Sediments of this section are often disturbed or removed by glaciation. At Grande Pile, the bog registered the entire Eemian pollen sequence between two glacial episodes (Fig. 1, zones A and C). The abundantly preserved pollen enabled a close study of the critical transition from zone 6a to 6b to be made (Fig. 2*c* and Fig. 3). A 5 cm-long section of organic sediment was taken from a core of Grande Pile, between two levels previously investigated for pollen, and corresponding to zones Eemian 6a and Eemian 6b respectively, (Fig. 2*c*). The selected section was prepared for thin sectioning, following the histological technique developed by Johansen[21]. Sections 250 μm thick, taken at 1-mm intervals along the 5-cm long core, were analysed for

pollen, and the results are presented in Fig. 3. One thousand arboreal pollen grains, at least, were counted at each level in three independent counts; percentages are based on the total sum of pollen grains. The time scale used here is based on comparisons with the work of Müller[14] at Bispingen, in northern Germany. Müller counted the annual varves through part of his record and estimated that the entire Eemian interglacial (equivalent of oxygen isotope substage 5e) lasted <11,000 yr. About 9,000 yr elapsed from the start of the *Betula* zone to the start of the *Pinus* zone. The same length of time is assumed to separate the beginning of zone 2 from the beginning of zone 6b in Grande Pile, at a constant sedimentation rate (see the Eemian zones in Table 1). A rate of about 6 yr mm^{-1} thus applies to the sediments of the sampled interval. The maximum error of this estimate may be ±50%.

The pollen data, within the 5-cm section, describe the history of local vegetation as follows (Fig. 3). From bottom to top, four phases can be observed: Zone 6a-top, tree pollen proportion is

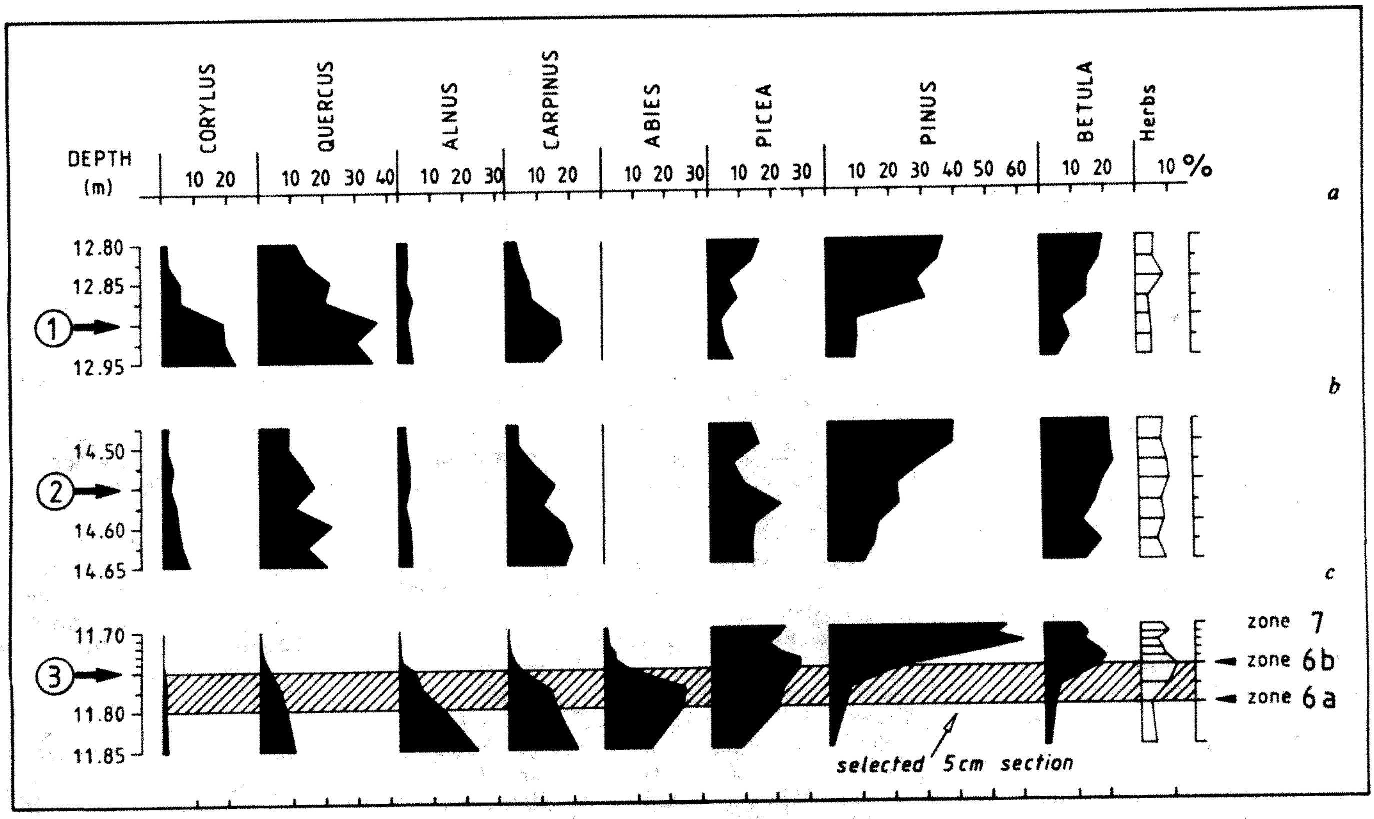

Fig. 2 Pollen counts (% of total pollen sum) across the levels of abrupt environmental change ending the three temperate intervals in Grande Pile shown in Fig. 1. Level 3 was counted in core Grande Pile III instead of Grand Pile X for technical reasons. (Depth level 11.75 in Grande Pile III corresponds to level 16.00 in Grande Pile X, shown in Fig. 1).

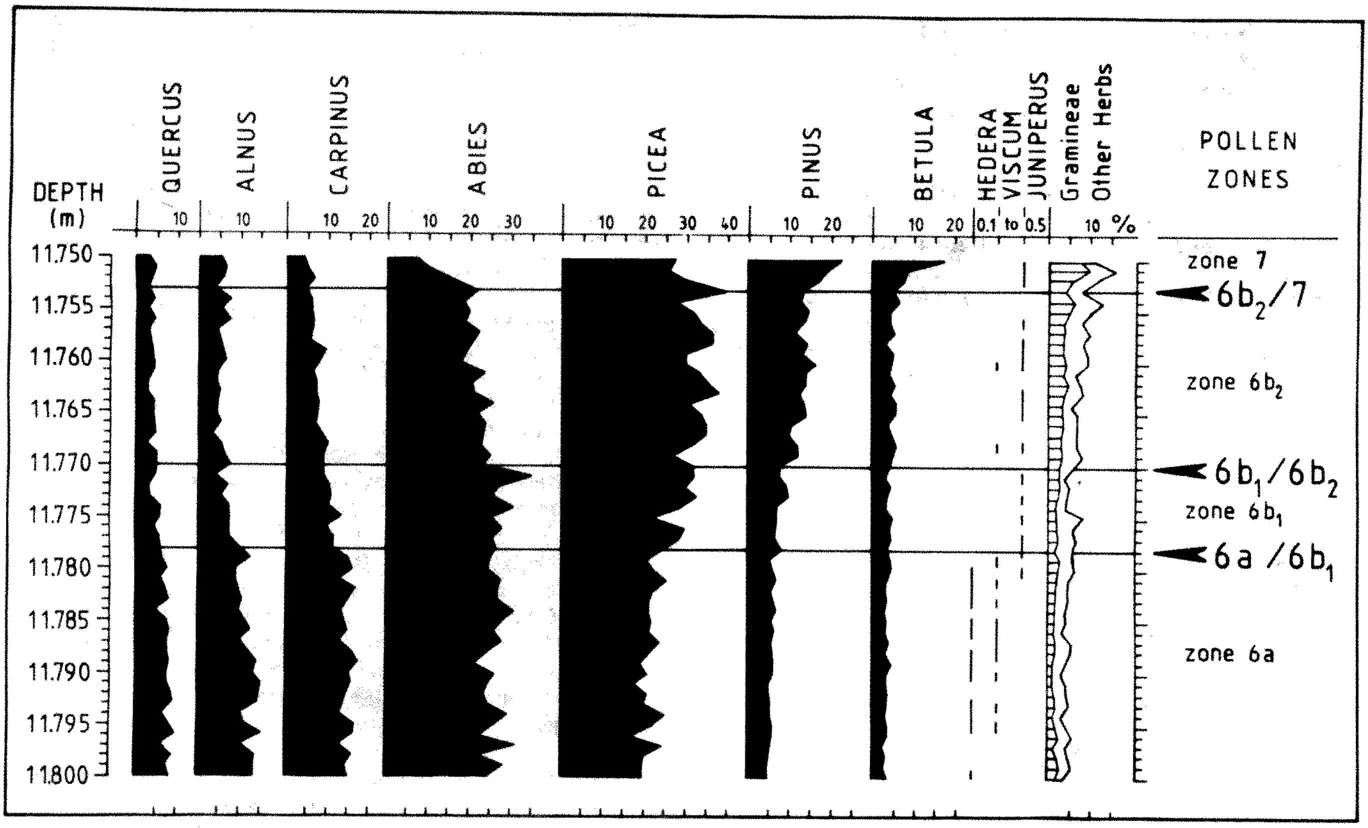

Fig. 3 Selected pollen types in % of total pollen sum. Taken from 250-μm thin sections at 1-mm intervals within the 5-cm segment shown in Fig. 2*c*. Estimated deposition rate is 1 mm per 6±3 yr, so that the segment sampled in detail covers 300 ± 150 yr. At each level 1,000 pollen grains were counted.

regular, with little variation, indicating a stable composition of the forest. Zone 6b$_1$, *Picea* gradually increases, competing with *Abies*: temperate elements decline. Zone 6b$_2$, *Picea* now clearly dominates over *Abies*: temperate elements are almost missing. Zone 7, Sudden expansion of *Pinus* and *Betula* and abrupt decline of *Abies*. (I assume that all the species involved in the competition existed in the pollination area of Grande Pile, within a radius of about 50 km.) Based on the time scale chosen, the upper part of zone 6a (22 mm thick) had a duration of ~130 yr, zone 6b$_1$ (8 mm thick) ~50 yr, zone 6b$_2$ (17 mm thick) ~100 yr, and zone 7 (3 mm thick) about 20 yr. Three relatively rapid changes in vegetation thus appear in the diagram. These are the 6a/6b$_1$ boundary where *Picea* dominates over *Abies* for the first time. Simultaneously, the temperate deciduous trees (*Quercus* and *Alnus*) decline, even the late-migrating *Carpinus*. Then, for ~50 yr, a close competition between *Abies* and *Picea* takes place, the latter gradually expanding. At the 6b$_1$/6b$_2$ boundary, the preceding trends become more pronounced. Now, we can clearly see the dominance of *Picea* and the rise of *Pinus*. The transitional period 6b$_2$ lasted ~100 yr. The main shift in vegetation apparently took place in only a few years, at the level 6b$_2$/7. The 6b$_2$/7 boundary is the best marked in the diagram: in ~20 yr, *Pinus* and *Betula* became with *Picea* the main constituents of the landscape while other trees, even *Abies*, were removed. The landscape is totally modified: the temperate hardwood forest is replaced by a boreal forest, common today in northern Scandinavia between 60 and 65 °N, that is some 15° lat further north than Grande Pile. But, change at the 6a/6b$_1$ boundary also seems to be important: it marks the irreversible decline of temperate elements (Table 1, zones Eemian 6b and 7). What happened at this level? The *Abies* behaviour on the Alsatian slope of the Vosges, during the very dry summer in 1976, might give one possible answer. *Abies* was seriously damaged by the severe summer drought; it was killed at the low altitudes and only survived in cool high areas. Clearly, repetition of such severe droughts would definitely exclude *Abies* from the Alsatian slope of the Vosges. But *Abies* is not the only species affected; all deciduous trees show a decline, even species resistant to drier conditions such as oak. The quasi-continuous presence of *Viscum* (mistletoe) which requires relatively high summer temperatures (+15.5 °C, after Iversen[22]), and that of *Hedera* (ivy) which requires mild winters (temperatures above −1 °C, after Iversen[22]), were ended. At the same time, *Juniperus* became common, a sign of transitions from warm to cold periods. These observations suggest that the change was primarily related to cooling and not to drought.

However, the pollen diagram alone cannot accurately reveal the cause of the change. The pollen curves record local and regional vegetation, and many local or regional factors, unrelated to climate, may modify the landscape[23,24] (soil structure, soil moisture, local or regional soil variations, competition between species, parasitic fungi and bacteria, destructive insects, diseases). Moreover, change of predominant wind direction may influence the pollen rain. Some pollen may be transported over long distances. For example, in the forest–tundra zone of the Nouveau-Québec, Canada, the pine area has its boundary at 55 °N, but the pollen is carried much further north. Heim[25] found 30.8% of *Pinus* in the tundra of Povungnituk, at 60° 34′N. Nevertheless, Heim[26] estimated that 60% of the total pollen represents the local vegetation, only 40% resulted from a regional pollen transport.

In Fig. 3, the change during 6a–6b$_2$ units proceeds gradually, suggesting that the controlling factor was non-episodic. The change at 6b$_2$/7 boundary is more difficult to explain, because it is so sudden. The continuity of sedimentation excludes any hiatus. The major break in vegetation, marked by the sharp rise of *Pinus* and *Betula*, might be due to sudden death of competitive species with higher climatic requirements. A similar replacement of a temperate forest by a boreal forest is observed at the end of all previous interglacials. It is, therefore, reasonable to assume that the sequence, shown in detail in Fig. 3, is typical, and mainly reveals the impact of global cooling on regional vegetation. This means that regional factors may have had an accelerating or delaying effect locally, and that different floral assemblages may have responded differently and at different rates to the climate change.

My pollen work shows that, in Grande Pile, the change from a temperate to a boreal vegetation occurred over 150 yr (±50%). The accompanying gradual decline in temperate elements would probably now be hardly perceptible to man, because of the artificial management of many European forests. We thus cannot exclude the possibility that we already live at the beginning of the present equivalent of the terminal interglacial pollen zone, and that we are heading towards a relatively fast, perhaps dramatic, 'borealisation' of West European forests which, some 115,000 yr ago, took <20 yr.

I thank Dr G. J. Kukla and Professor W. Mullenders for reading the manuscript, and P. De Deckker and P. Roucoux for assistance.

Small non-passerine birds of the Lower Tertiary as exploiters of ecological niches now occupied by passerines

C. J. O. Harrison

48 Earl's Crescent, Harrow, Middlesex, UK

In spite of the rather inadequate sample of past avian populations provided by the chance preservation of fossil bird bones, the increasing accumulation of such material makes it possible to speculate on the composition of early faunas and to consider the apparent relative dominance of major groups, such as passerines and non-passerines, in earlier geological periods. An examination of the range of species that we now know occurred in the Lower Tertiary of Britain appears to confirm that passerine birds were very scarce and that their great adaptive radiation had not taken place. Their ecological niches were seemingly occupied by small non-passerine land birds, species of this size appearing proportionally more numerous than at the present day.

Recent studies of British Lower Tertiary birds, involving both new and previously-described (but not always correctly identified) material, have greatly increased the number of species known. The total of British Lower Eocene species from the Woolwich and Blackheath Beds and London Clay of the London Basin, and the London Clay of Bognor Regis, Sussex, has risen from 8 to 31 (ref. 1); six species have been described from the Middle Eocene Bracklesham Beds of the eastern Hampshire Basin[2]; the Upper Eocene avifauna from the Barton Beds of the Hordle area of the Hampshire Basin has increased from 9 to 13 (ref. 3), and five species have been described from the Lower Oligocene Hamstead Beds and Bembridge Marls of the Isle of Wight[4]. Further undescribed species are known from the Lower Eocene London Clay of Essex and the Middle Eocene Barton Beds of the Hampshire Basin. Sixteen orders and twenty-three families are now known to be represented in the Eocene and Lower Oligocene of Britain, and by the standards of modern temperate regions this constitutes a reasonable sample of a local avifauna at this taxonomic level, but lacks the complex adaptive radiation of passerines.

As might be expected from these water-borne deposits, most of the species are waterbirds, and include seabirds. The bone fragments of these species are mostly of moderate to large size and are referable to forms which, for the most part, are within the size range of Recent species in the taxa involved, but tend to be towards the upper end of these ranges. This is not surprising because large bones are more likely to be preserved and be noticed.

Collectors, when working in the field, tend to look for material within a particular size range, and there is apparent evidence of this type of 'search image' bias in the British Upper Eocene material. The earlier collections of Upper Eocene avian specimens[3] consist almost entirely of bones or bone fragments more than 23 mm long and fairly thick; but R. Gardner, while searching for the remains of small mammals in the same Barton Bed deposits that yielded the earlier material, recently collected several fragments mostly less than 10 mm long and 2–3 mm thick. Because these included bones of a new small wader and small passerine-type bird, the remains of small species have clearly been overlooked, and a higher proportion of such species is to be expected from future collecting. In spite of the mainly marine and estuarine origins of these Early Tertiary deposits in Britain, the terrestrial avifauna which has been preserved in them is surprisingly large. The term terrestrial is used here to indicate both cursorial and arboreal land birds, as opposed to species from marine, littoral or lacustrine habitats. The size distribution of these terrestrial non-passerines differs from that of the birds as a whole, as the following list of British forms indicates. In it, except where noted, the birds are from the Lower Eocene. The names of some Recent genera and species are given in parentheses to indicate relative sizes of the fossils concerned.

Falconiformes: one large (buzzard, *Buteo*), one medium-sized from the Middle Eocene (kite, *Milvus*), one very small (pygmy falcon, *Microheirax*); Galliformes: two large from Middle Eocene and Lower Oligocene (junglefowl, *Gallus*), one medium-sized (common partridge, *Perdix perdix*), four small, with one from the Middle Eocene, (from two-thirds partridge size to size of quail, *Coturnix*); Columbiformes: one very small (diamond dove, *Geopelia cuneata*, smallest Recent pigeon); Psittaciformes: one medium-sized (Senegal parrot, *Poicephalus senegalus*); Strigiformes: one a little smaller than the little owl, *Athene noctua*; Cuculiformes: one large musophagid, three tiny cuckoos (bronze cuckoos, *Chrysococcyx*); Coraciiformes: one medium-sized (song thrush, *Turdus philomelos*).

Thus, by comparison with the size ranges of the Recent species in the taxa concerned, and in circumstances where there is a tendency for large rather than small species to be collected, of the eighteen species from these seven orders four were large, four medium-sized, and ten small to very small. In this preponderance of small forms the early avifauna differs markedly from Recent taxa. Although about a third of Recent owl species are small, and about one-sixth of phasianid gamebirds; only about

0028–0836/79/420562—02$01.00

14 of 131 cuckoos, 11 of 286 pigeons and nine of 263 diurnal birds of prey come into the latter category. Because most of the small fossils were found at the same sites as medium and large ones there is no suggestion that selective transport of material in a marine environment before final deposition has influenced the size range of specimens; and on present evidence these early terrestrial birds show an exceptionally high proportion of small species.

In Recent terrestrial avifaunas most small birds are passerines, Passeriformes. They form 65% of the terrestrial avifauna of Europe; and in a world study of Recent avifaunas, Slud[5] found an overall ratio of 2:1 between passerines and non-passerines in terrestrial faunas, with a slightly higher ratio in forested than in non-forested regions.

The Passeriformes are very poorly represented in the Lower Tertiary. One species has been described from the Lower Eocene of Britain[1] and another has been identified provisionally from the Upper Eocene. Fisher[6] lists one Lower-to-Middle Eocene species from North America which Feduccia[7] has re-identified as piciform, and four Upper Eocene passerines from France which Brodkorb[8] regards as *incertae sedis*. Brodkorb has also questioned the existence of any passerine birds before the Miocene. At best passerines would form only 10% of the known terrestrial avifauna of the British Lower Tertiary. Because the range of forms includes very large and very small birds, representatives of families in which the present species are almost entirely arboreal, and a number of taxa in which the Recent birds have poor powers of flight, there is no reason to suppose that passerine species, if present at that time, would be any less likely to occur as fossils than these other small species.

Assuming that the known fossils are a reasonable sample of the British Lower Tertiary avifauna, then that avifauna differed from all present ones in having a severe deficiency of passerine species, and in a preponderance of small species among the other orders. Most of these small non-passerines probably fed on seeds or insects and other small organisms, thus occupying the main types of feeding niches of Recent passerines. I suspect that the two differences are linked, and that non-passerines originally occupied feeding niches available for small birds, and were later excluded from these by the adaptive radiation of the passerines. This would in turn have affected the opportunity for survival and adaptive radiation of small non-passerine species.

Complex systems which evolve towards homeostasis

Ken Tregonning* & Alan Roberts

Department of Physics,
Monash University, Clayton, Victoria 3168, Australia

It is still not well understood how large complex systems (such as ecosystems) come into being or how they persist over long periods of time, although recent studies$^{1-5}$ have clarified certain aspects of the associated stability problems. The occurrence of such systems presents no problem if a teleological assumption is valid—that is, if the variables may be presumed (or compelled) to adjust their mutual interactions in advance, to achieve the desired persistence. But when no such 'foresight' is credible, a real problem emerges; how a given variable can interact will generally be constrained by factors internal to it, independent of the 'needs' of other variables or of system stability. This consideration has prompted studies of 'randomly-interacting' system models, and interesting results have emerged$^{1-4}$ concerning the stability of such models—that is, their capacity to return to equilibrium after a fluctuation. However, the question remains: how did such a collection of randomly-interacting entities arrive at an equilibrium in the first place? We present here results from a simple model using mutually interacting variables. We show how, even on assumptions which make large complex and persistent systems highly improbable initially, they can nevertheless be expected to arise in profusion in the normal course of time development.

To fix ideas, our model is presented as an ecosystem but the field of application is much wider. Such an extension is possible because we have not included specifically biological mechanisms; thus, from an ecological as from any other particular viewpoint, the model is bare and lacking in realistic detail. This is deliberate; we seek the consequences of this very general model itself—the 'mathematical' consequences—rather than those peculiar to the one field of application.

We consider, then, a collection of M species in which the (i)th has an intrinsic increase rate r_i (positive for a producer, negative for a consumer). Its interactions with the other species are fully described by $(M-1)$ 'interaction constants' A_{ij}, and A_{ii} describes its self-interaction. The time-dependent variable $N_i(t)$ is taken to measure its population, population density or biomass.

A simple form for the system's equations of motion was chosen, sometimes called the generalised Lotka–Volterra (GLV) equations, but here referred to as the multispecies quadratic (MSQ) model. (This avoids confusion with other definitions of 'GLV model'.) These equations are;

$$\mathrm{d}N_i/\mathrm{d}t = N_i\Big(r_i + \sum_j A_{ij}N_j\Big), \qquad i = 1 \text{ to } M \qquad (1)$$

To investigate the time behaviour, we proceed as usual (see for example ref. 5). The equilibrium values N_i^* are found as the solution of the matrix equation

$$AN^* = -r \qquad (2)$$

The local stability/instability of the system about these equilibrium values is then determined by the absence/presence of eigenvalues of S with a positive real part, where $(S)_{ij} = \mathrm{N}_i^*\mathrm{A}_{ij}$. However, this stability character has no meaning unless the equilibrium point is 'feasible', that is, unless all the N_i^* are positive[3]. A system which is stable about a feasible equilibrium will be called 'homeostatic'.

In computer studies on this model, we have taken the A_{ij} $(i \neq j)$ as non-zero with probability C (the connectance), and then of constant magnitude g. The self-interaction coefficients A_{ii} and the increase rates r_i were chosen as having magnitude 1. By allowing the non-zero A_{ij} and the r_i to be positive or negative with equal probability, a 'random ensemble' was generated for study.

Initial results for M ranging from 2 to 10 have already been reported[5], and are briefly summarised here. In this model, despite its ecological poverty, the subset of homeostatic systems is reminiscent of real ecosystem behaviour—in particular, in the popularity of predator–prey interactions $(A_{ij} < 0, A_{ji} > 0, r_i > 0, r_j < 0)$, the fraction of consumers tolerated $(r_i < 0)$ and the necessity for nearly all species to be self-regulated $(A_{ii} < 0)$. In all these ecosystem-like properties, the simple requirement of homeostasis picks out a subset very different from the rest of the random ensemble.

But in one important respect, the model fails badly: it gives far too low an estimate of the chance that such a random collection of species will be homeostatic, that is, persistent. This chance lies below 2^{-M}, or, for as few as 20 species, less than one in a million. Thus other mechanisms must be considered, if the model is to yield a plausible likelihood for the occurrence of large systems.

Table 1 Results of species elimination

	Elimination method: Random	Elimination method: Natural selective
Maximum no. of eliminations required for homeostasis	50	29
Mean no. of eliminations required for homeostasis	46.7	25
Fraction of sample yielding a non-trivial homeostatic system	24%	100%
Fraction of feasible systems stable	100%	100%
Largest homeostatic system resulting	4	29
Smallest (non-trivial) homeostatic system resulting	2	21
Mean ratio of connectance in homeostatic set to that in random ensemble	0.80	0.99
Fraction of eliminated species which were consumers	0.50	0.826
Maximum fraction of consumers in a homeostatic system	0.33	0.25
Minimum fraction of consumers in a homeostatic system	0.00	0.11
Mean fraction of consumers in a homeostatic system	0.20	0.165
Ratio of mean no. of eliminations to initial no. of unfeasible species	1.82	0.99
Final range of values of g	0.88–1.25	0.33–0.39

Sample of 25 from a random ensemble of self-regulated species collections ($A_{ii} < 0$ for all i), with $M = 50$ (25 consumers, 25 producers), $C = 0.2$, $g = 0.25$ initially. Starting with inhomeostatic systems of 50 species, species are successively eliminated and the interaction strength 'scaled' (see text), until a homeostatic system is achieved. In the random elimination method all species have equal chance of removal. A 'non-trivial' system is one containing 2 or more species.

One might think that specifically biological mechanisms now need to be invoked—for example, the evolutionary processes which lead to what Wilson has called 'adaptative equilibrium'[6]. However, we report here a study which invokes no such 'external' consideration, but derives the higher likelihood desired from the bare model itself. This is achieved as follows: Either of the defects which imply inhomeostasis—unfeasibility, or instability—can be expected to result in the eventual disappearance of one or more species, so that the original collection does not persist in time. Furthermore the elimination of species might proceed until only a handful of species remain, perhaps none at all; but alternatively, the residual system might be comparable in size to the original collection. We have tested for this latter possibility, generating random assemblies as described above, but imposing $A_{ii} = -1$ always to ensure the possibility of homeostasis[5].

Starting with a random (almost always inhomeostatic) collection of 50 species, if it is unfeasible we eliminate the species with the most negative equilibrium value N_i^*. A second criterion was adopted to choose the species most likely to disappear from a feasible but unstable collection; we omit this criterion, for reasons evident below. Both criteria are intuitively appealing, and can be supported. The resulting collection of 49 species is then examined. If it is still inhomeostatic, another species is eliminated using the same criteria; this procedure is repeated until a homeostatic system is obtained, or all species disappear. (On reducing the number of species, say to M', we increased the interaction parameter g to g' so that $(M'-1)^{1/2}g'$ kept its initial value $(M-1)^{1/2}\,g$. For the rationale of this 'scaling' (note that it makes homeostasis harder to achieve in the smaller system) see refs 2 and 5.)

Table 1 gives detailed results for a sample of 25 assemblies treated as described. It will be seen that inhomeostasis, whether initial or final, always stemmed from unfeasibility; feasible systems were always stable. (Other evidence for this finding in the kind of parameter range studied already existed, though for a less general model consisting of producers only[3].)

The major result is that no assembly 'collapsed' to fewer than 21 species, and one retained 29. The mean number of species remaining in the final homeostatic system was 25, or half the original number.

The large size and complexity of the final system depended on the elimination being 'natural-selective', that is, designed to mirror the actual result of development in time. This is readily seen from Table 1, by comparing the results with those of 'random' elimination, where such a rationale was lacking; the largest homeostatic system then achieved held only four species, and most of the species had no interspecific interactions.

In the homeostatic systems arrived at by selective elimination, the distribution of interactions was examined; it was not detectably different from that of homeostatic systems obtained in random choice from the ensemble. Moreover, the connectance C remained essentially unaltered in the passage to homeostasis. Thus, if we want to construct a typical large homeostatic system, of size $\sim M$ and connectance C, it is quicker to generate an assembly (almost certainly inhomeostatic) of $2M$ species with connectance C, and let it achieve homeostasis by natural-selective elimination. The alternative is to continue generating assemblies of M species until a homeostatic one appears; we estimate that, for M as small as 25, the elimination method is quicker by a factor exceeding 500,000.

It is evident that, in the natural evolution of such assemblies if randomly generated in time, almost all large, multispecies systems will be those arrived at through elimination. Moreover, they will appear with far greater speed, and thus with far greater likelihood, than would be suggested by the (tiny) proportion of the random ensemble that they constitute.

We thank Dr Chris Wallace for stimulating discussions.

Heart attacks and geomagnetic activity

E. G. Knox, E. Armstrong & R. Lancashire

Department of Social Medicine, University of Birmingham, UK

M. Wall & R. Haynes

West Midlands Regional Health Authority, Birmingham, UK

Malin and Srivastava[1] reported a remarkable correlation between daily variations in the geomagnetic field strength and daily admissions to the cardio-thoracic wards of hospitals in Hyderabad and Secunderabad, for cardiac emergencies, during 1967–72. We have now carried out a similar enquiry in the West Midlands region of the UK for the years 1969–70, but were unable to confirm the Indian results.

The medical data consisted of daily admissions for acute myocardial infarction to all hospitals in Warwickshire, including Coventry, Birmingham, Solihull and Sutton Coldfield, during a period of 720 days beginning 1 January 1969. The data were extracted from the Hospital Activity Analysis records of the West Midlands region. The geomagnetic data consisted of the daily sums of the 3-hourly 'Kp-values' obtained from catalogues of recordings taken in the UK[2]. Fluctuations at three geographical sites were reported and agreed closely; the data used in the analysis were those recorded at the station at Hartland,

0028–0836/79/420564—02$01.00

UK. There were 6,298 hospital admissions over a 720-day period, a mean of 8.75 per day. The 'Kp-sums', also consisting of integer values, averaged 15.73 per day. Analyses were carried out with both the raw data (n) and logarithmic transformations ($\log_{10}(n+1)$).

Same-day correlation coefficients were calculated between the two values within each of 24 successive 30-day periods. Serial correlations were calculated, separately for geomagnetic activity and for heart attack admissions, between pairs of readings separated by 1, 2, ... 31 days. Finally, over the full 720-day period, correlations were calculated between geomagnetic readings on day 0, and hospital admissions on days −15, −14, ... +14, +15 days.

The results were qualitatively similar for the raw and the log-transformed data. Results reported below refer to the log transforms. The serial correlations of the admission data gave significant values (> 3 s.e. from 0) at 7 days ($r = +0.15$), 14 days ($r = 0.16$) and 21 days ($r = 0.12$). A complex day-of-week variation over the full period ($\chi^2_6 = 67.8$), mainly characterised by a deficiency of admissions on Sundays, confirms the validity and demonstrates the origins of this finding. The serial correlations of the geomagnetic data gave significant positive results (> 3 s.e.) at 1/2 days ($r = 0.50$ at 1 day), 16/17/18/19 days (0.17 at 17 days) and 25/26/27/28 days (0.21 at 27 days). The 27-day cycle represents the period of rotation of the Sun. None of the 720-day-period correlations with intervals of −15, ... 0, ... +15 days showed significant positive or negative correlations; the greatest absolute value was $r = +0.06$ (1.46 s.e.). None of the intra-30-day-period same-day correlations between medical and magnetic data gave a significant value, either positive or negative.

Despite the fact that our methods and materials were sensitive enough to detect serial correlations within each of the individual data sets, our examination failed to confirm the Indian observations. Although there is no clear explanation of the difference between the two investigations, three hypotheses should be considered: (1) heart attacks may have different aetiologies in the two countries, (2) the two sets of electrocardiographic equipment may differ, the Indian equipment being susceptible to external magnetic fields, thus affecting the relative likelihoods of different diagnoses, (3) temporal fluctuations in the Indian medical data, with a period differing from our own 7-day cycle, and due to different social customs, may have interacted coincidentally with one or other of the periodic variations observed in the geomagnetic field.

Perception of illusory movement

Alex Fraser & Kimerly J. Wilcox

Department of Biological Sciences, University of Cincinnati, Cincinnati, Ohio, 45221

Intensive studies of visual illusion have rarely shown examples of polymorphic responses[1–3]. We show here that, using figures consisting of stripes shaded from dark to light, arranged in repeating sectors, an illusion of movement can be induced in about 75% of observers when viewed peripherally. The responses of the viewers fall into four categories. This polymorphic response suggests a genetic origin.

Figure 1 shows the figures used during the experiments. The four categories of response into which viewers could be divided were: (1) N, seeing no movement, or a slight, inconsistent, jerky motion; (2) DL, seeing smooth continuous movement in the direction from dark to light shading; (3) LD, seeing smooth, continuous movement in the light to dark direction; and (4) V, sometimes seeing smooth, continuous movement in the DL direction, sometimes in the LD direction. The individuals of the N class who see a slight, jerky movement consistently see this in the DL direction. A sample of 678 subjects showed 24.9% N, 59.0% DL, 6.5% LD and 9.6% V. The subjects were tested with two figures in which the shaded sectors were arranged in a spiral and the polarity of the shading was opposite. Sensitive subjects see the illusory movement in opposite directions in the two figures. Care was taken not to bias the responses of the subjects who were simply asked to give their responses to the figures, no mention being made of motion, rotation, and so on. Reaction to the figures in repeated tests separated by intervals ranging up to 2–3 years is remarkably constant, that is, the classification has a high repeatability.

The polymorphism of response suggested a genetic explanation and, therefore, a parent–offspring survey was made of individuals in 83 families. The LD and V classes were grouped to give the data shown in Table 1. There are no differences between sexes nor between reciprocal matings, and the data have been grouped over sexes and reciprocal matings. If we examine the types of matings from N × N to N × DL, to DL × DL, to DL × LD–V, there is a progressive decrease of the frequency of N progeny. There is a clear parent–offspring correlation, indicating that there is either a strong genetic causation or an equally strong familial effect of common environmental factors.

A number of twins were tested to allow separation of genetic and environmental factors. Concordance was computed as the number of twin pairs having the same response divided by the total number of twin pairs. The concordance for MZ twins (29 pairs) was 0.90, for DZ twins (41 pairs) was 0.56, and for non-twin sibling pairs was 0.53 (213 pairs). The concordance for unrelated pairs was 0.40. The differences between MZ and DZ twins are significant, indicating that there is a fairly strong genetic component. Clearly, more data are needed, but the agreement between the parent–offspring and the twin comparisons indicate that the illusory-movement perception (which we are terming the 'escalator' illusion) offers considerable promise for further detailed studies.

If our data are sub-divided by academic disciplines it is apparent that the incidence of the escalator effect differs between academic disciplines. Faculty and graduate students of three departments were tested: Fine Arts, 4.7% N (42 tested), Biological Sciences, 22.5% N (40 tested), Psychology, 56.2% N (42 tested). The Biological Sciences department does not differ from the general expectation of 24.9% N. The other two departments differ significantly from each other, and from the general expectation. Tests of progeny of Fine Arts and Psychology faculty gave the following results: Fine Arts, 5.9% N (17 tested), Psychology, 35.0% N (20 tested). The regression of the progeny towards the population mean of 25% agrees with the genetic determination of the character. These results support the surprising conclusion that genetic differences in

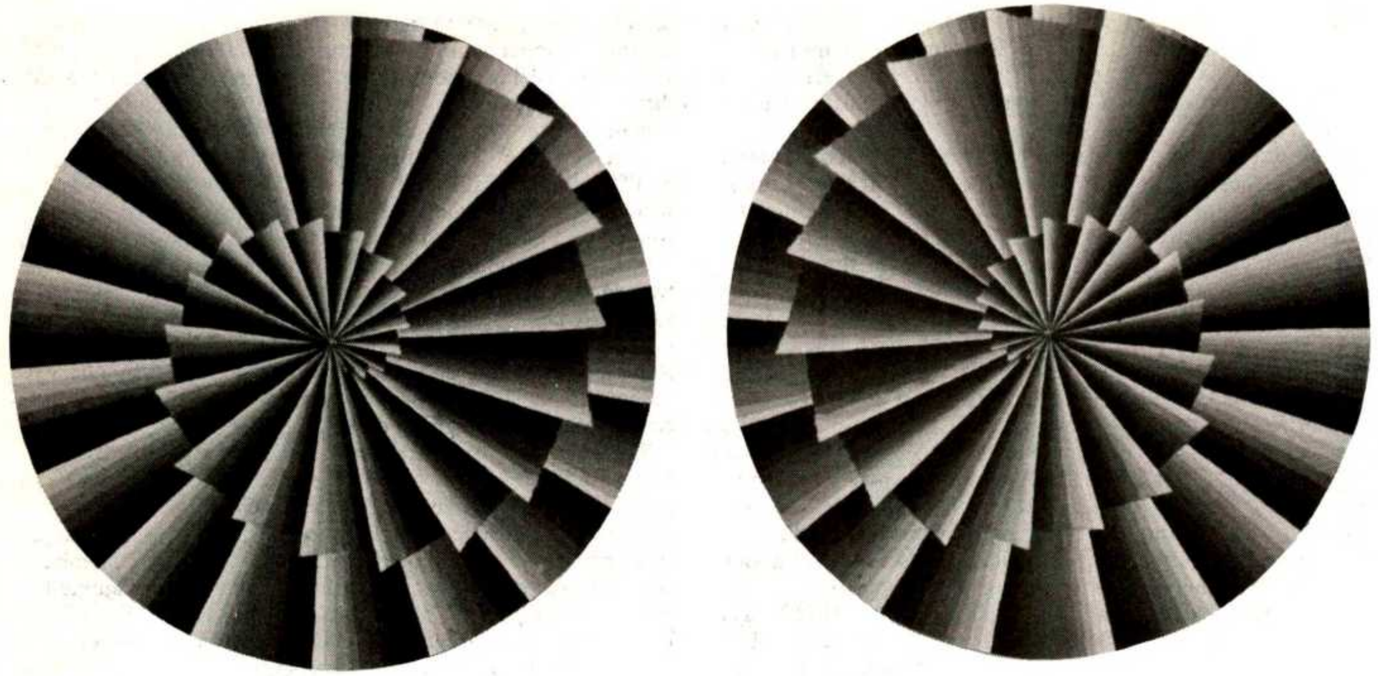

Fig. 1 The two illustrations presented to observers.

sensitivity to the 'escalator' figures are involved in career selection. We have identified in our sample of Fine Arts undergraduate students, five who transferred out of the programme. All were N ($P = 0.001$). Presumably the complementary process occurs in the Psychology programme. Genetic determinism of a sociological polymorphism is known—similar differences between career groups can be found for colour blindness.

'Escalator' illusion is a feature of peripheral vision not occurring within 5° of the point of fixation when seen at distances of several feet. The possibility that this phenomenon is due to small polarised eye movements is discounted, (1) by seeing simultaneous rotation in opposite directions in spiral figures, (2) by seeing simultaneous movement in opposite directions in parallel and rectilinear figures, and (3) by seeing the simultaneous different movements continuously whilst making fairly large eye movements.

Tests were made to determine whether real rotation would suppress or enhance the rotation of the figures induced by the 'escalator' effect. The two figures were mounted side by side and rotated at the same rate. Subjects viewed these figures peripherally centering their vision mid-way between the figures and below them. The two disks were concordant, having their DL shading in the same direction, or discordant, one disk having the DL shading in the clockwise direction whereas its neighbouring disk was shaded DL in the anticlockwise direction. It was found that if the rate of rotation is slow (0.68 r.p.m.) then DL subjects differ in their perception of the rates of rotation of the disks, depending on whether they are concordant or discordant. They see the concordant disks as rotating at the same speed in 91% of trials. Conversely, they see in the discordant disks, one disk as rotating faster than the other. The disk seen as rotating at a faster rate is the one in which the DL shading is in the same direction as the real rotation. This was reported in 68.0% of trials. If the real rotation is reversed, then the identification of the faster disk is also reversed. N subjects gave quite different results in their perception of the discordant pair of disks, reporting the expected difference in apparent rate of rotation in only 18.0% of trials. At slower rates of rotation the agreement of results with expectation increased to 90.0% in DL subjects and to 59.7% in N subjects. At very slow rates of rotation in the range of 0.1–0.4 r.p.m., DL subjects note for the discordant pair of disks that the disk in which the DL shading is in the opposite direction to the real rotation, appeared to be stopped whereas the adjacent disk was still perceived as rotating. Reversing the direction of the real rotation reversed the identification of the disk that was not rotating. N subjects noted the same apparent cessation of rotation only at lower rates of rotation 0.12 r.p.m. and with less consistency. It is apparent that our original test procedure does identify a real difference of visual perception, with the difference being of degree: N subjects are not 'blind' to the 'escalator' effect, but have a much lower sensitivity than DL subjects.

It is rather surprising that the intensive studies of visual illusions[1–3] have rarely identified examples of polymorphisms but a possible explanation of this is that such studies have involved refining figures until they are 'strong'; that is perceived by all subjects in all conditions. If figures are, instead, refined to maximise discrimination, then it is possible that polymorphisms of visual perception will be found to be as general as polymorphisms of other characters.

Underwater behavioural thermoregulation in the adult stonefly, *Zapada cinctipes*

William Tozer

Division of Entomology and Parasitology, 201 Wellman Hall, University of California, Berkeley, California 94720

Some adult insects survive extremely low temperatures using various physiological mechanisms[1,2]. Here I report that the adult stonefly, *Zapada cinctipes* (Banks) (Plecoptera: Nemouridae), behaviourally thermoregulates at subzero night temperatures by entering the water.

The study site, a small pond formed by an artificial diversion of Sagehen Creek, was located in the Sierra Nevada Mountains 9 km north of Truckee, California (39°25′N, 120°12′W, elevation ~2.0 km).

After typical[3] midday (11.30 a.m.–2.30 p.m.; 13.0–25.0 °C) aerial or surface oviposition (no species of stoneflies in North America have ever been observed to oviposit underwater[4]), a female would generally fly to the centre of the pond and land on the ice. She would then walk to the south-west edge of the ice, crawl into the water and awkwardly swim ~ 0.5 m to within 0.25–0.50 m of the shaded shoreline. Next, she moved beneath the water surface by grasping pine stems and branches protruding above the water. (An adult possesses two pairs of cervical gills and these, in addition to being partially enveloped in a film of air, may enhance underwater oxygen diffusion.) A descending female would wave each antenna in front of her in an apparent searching pattern, although contact was rarely made with the object used for descent. This descent continued to a depth of 15–20 cm, where she remained relatively motionless in the clear water for periods of 20–60 min. (Females placed underwater in wire cages in the same location and raised to a point just below the water surface for inspection at 5-min intervals lived as long as 80 min.) A female would then climb to the surface and float for 1–5 min before submerging again. No females collected before submerging were ever observed to be extruding egg masses. This procedure was repeated continuously up to 5 h after sunset, even after a thin layer of ice had sometimes re-formed on the surface. The outlines of air spaces could be seen immediately under the clear ice cover at irregular intervals along the shoreline. It is within these air pockets that adults are presumed to have obtained surface oxygen, for live adults were subsequently collected on the surface as the ice melted in the early morning. To test for possible oviposition in the night, upper leaf debris and then 2–3 cm of underlying substrate were removed from the pond. Microscopic examination failed to reveal any eggs.

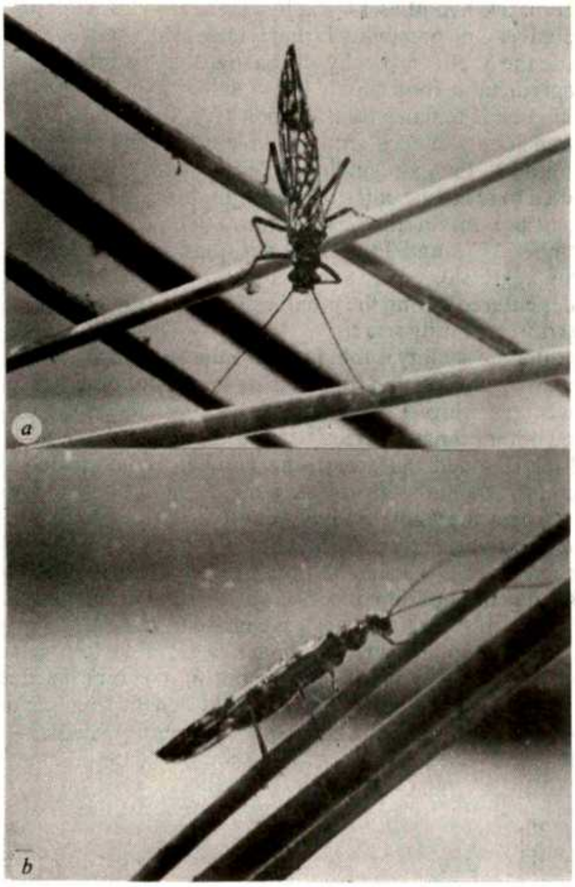

Fig. 1 *a*, *b*, Underwater views of an adult female *Zapada cinctipes* (Banks) after submerging at 5.0 °C air temperature (×2.5).

Such underwater activity was observed for 37 females during 4–18 April 1977. From 19 to 24 April, during late afternoon, adults were more commonly observed to land in open areas along the shoreline and seek refuge in rock crevices and beneath leaf debris (previously inaccessible because of snow cover), where they remained until morning. For the period 4–24 April, mean minimum night air temperature was $(\bar{x}\pm\text{s.e.})-6.2\pm0.7$ °C, and the higher mean minimum water temperature 8.6 ± 1.0 °C.

To test the effect of temperature on survival, 12 individuals collected on 8 April were randomly divided into two groups. The first group was placed in a $0.5\times0.2\times0.1$-m wire cage and half submerged in the pond. The other six were placed in a similar cage, but kept along the shoreline and partly covered against solar overheating. Pond drinking water was renewed daily for the latter group to control for differential mortality from desiccation; gut analyses of both groups (all guts were empty) confirmed an initial assumption that food was made unavailable by caging. Consequently, mean longevity of the first group ($\bar{x}=8.5$ d), with access to the pond, was significantly greater than the second group ($\bar{x}=1.7$ d), which was exposed to subzero night air temperatures ($P<0.005$; Mann–Whitney test).

An additional field experiment was carried out on 21 April 1979 to measure thermal avoidance more directly. To preclude possible light entrainment, this experiment was carried out at times when underwater behaviour has never been observed. (Testing times, air temperatures and water temperatures for both trials were: 10.20–11.05 a.m., 15.0–16.1 °C and 10.0 °C; 1.05–1.52 p.m., 18.0–19.5 °C and 10.4 °C.) The apparatus consisted of a $14.0\times5.4\times14.5$-cm Plexiglass chamber half filled with pond water and submerged in the pond to this same level. Two newly collected females per trial were initially positioned 3.5 cm above the water on pine stems extending the height of the chamber. The top, made of paired sheet aluminium baskets filled with dry ice and separated by an insulated sliding thermistor, was then sealed against CO_2 leakage. At $\sim$6–12 °C, responses consisted of localised repositioning and antennal tip bending and shaking alternately towards the top of the chamber and the water surface. At 4.8–6.1 °C, all stonefly adults moved completely underwater (Fig. 1) for 15–42-min intervals. Adults left the water when air chamber temperatures approached ambient.

A single female submitted to the same experiment at 3.00 p.m., but without access to water, went into a torpor at 3.5 °C. If immediately removed from the chamber and warmed, she recovered and seemed to exhibit normal locomotory behaviour. But, when left at the same temperature for 2–3 min she did not recover.

It seems important that at high altitudes where daily air temperatures fluctuate greatly[5] and winter conditions are severe, endothermic or ectothermic regulation is used by adults as an adaptive survival strategy. Because endothermy for small insects is too energetically costly[6], regulation of body temperature by stonefly adults moving to a relatively constant thermal environment (a pond or lake) may be of considerable evolutionary significance. Such a hypothesis is not without support, for in nearby Lake Tahoe both nymphs and adults of the stonefly, *Capnia lacustra*, have been found to live at depths of 60–80 m (refs 3, 7). Although the behavioural flexibility exhibited by such species seems rather remarkable, limits imposed by poor dispersal abilities[3,8] must be seriously considered in the light of man's increased impact on these faunal refuges.

I thank Drs B. Heinrich, H. B. N. Hynes and M. L. May for critical reviews of the manuscript, and Dr V. Resh, D. Hart, and L. Orsak for valuable comments.

Female transference and mate choice among Tana River red colobus

C. W. Marsh

Department of Biology, Universiti Kebangsaan Malaysia, Jalan Pantai Baru, Kuala Lumpur, Malaysia

Red colobus are one of a small number of primate species in which females have been reported to transfer between breeding groups more commonly than males[1-3]. Several authors have hypothesised that in such species transference may serve to reduce the risk to females of producing offspring of lower fitness through inbreeding[1-6]. The hypothesis offers no explanation of why females rather than males are responsible for outbreeding in these species, but remains plausible so long as male membership of breeding groups is relatively stable; for once members of one sex have evolved dispersal mechanisms reducing the risk of inbreeding, pressures on the other sex to do likewise will be lowered[5]. Hence, if both sexes commonly migrate, the hypothesis is weakened. I describe here the membership dynamics of a group of Tana River red colobus, *Colobus badius rufomitratus*, which provide the first evidence of high rates of membership turnover by both sexes in primates, and speculate that the function of female transference in this case may be related to mate choice and the avoidance of infanticide.

The data come from a 3-yr study carried out between 1973 and 1975 near Wenje, in Eastern Kenya. The habitat consists of small patches of riverine forest, differing markedly in size, diversity and seasonality from the rain-forest habitats where red colobus are more widely distributed[7]. The social structure of the Tana population also differs from that reported from rain-forest sites in Tanzania and Uganda[8,9]: instead of multimale groups of about 50 animals, the population is dispersed in groups of 12–30 animals, often containing only a single adult male and never more than two.

Reliable censuses of the main study group were obtained in 24 months between June 1973 and October 1975. During this period the size of the group varied from 16 to 33 animals, with a mean of 21.5. Only a single adult male was resident in the group at one time but there were two replacements during the study. The first occurred in July 1973 and was not observed, and the second took place 5 months later over a 3-day period in January 1974, after which the new male remained for at least another 21 months until the end of the study.

Changes in the number of adult females in the group are shown in Fig. 1. Net gains and losses seem not to have occurred in random sequence (runs test, $P < 0.05$ (ref. 10)), but rather to have involved a rapid decline, followed by a slow increase. The point of reversal in the trend coincides closely with the replacement of the second male in the group. When he joined in July 1973, the group contained 14 adult females and 4 clinging infants. By December, there remained only 8 females, 7 of which carried infants: at least 4 infants had been born in the interim, and one had died. Evidently, in this period pregnant females or those carrying infants tended to remain in the group, while those without young emigrated. On the other hand, after the second replacement in January, female numbers slowly increased to reach a maximum of 19 adults and 3 subadults by the end of the study. With only one exception the increase in adults was due to immigration rather than to the maturation of subadults within the group.

Evidence from known individuals on the origin of immigrants or the fate of emigrants is scarce. Of 11 individually recognisable females, 3 disappeared from the group and 2 were sighted elsewhere. One successfully transferred to a neighbouring group and remained there for at least 16 months, while the other was seen only once in a group some 2 km from the edge of the study group's range. As solitary females were sighted only three times during the study, while solitary males were seen quite commonly, females probably transferred rapidly between groups.

These findings are of interest for three reasons. First, the rate of female movements was extremely high: a total of 34 were inferred over 29 months. Second, the migrations were made by adults 27 times and subadults 7 times, but never by independently-moving juveniles (although two moves were made by adult females carrying small juveniles). Among red colobus in Uganda, females also transfer between groups, but in this case juveniles are the mobile element and the migration of adults has not been reported[3]. If migration served simply to avoid inbreeding, transference at juvenile or subadult age would suffice, and the frequent migration of adults would not be expected. Third, the movements occurred despite two male replacements in the group. Again, if their function was to reduce the risk of inbreeding, they would seem to have been superfluous (unless, conceivably, successive males in the group were closely related individuals).

Alternative hypotheses to explain these findings are at present speculative. One possibility is that females shift between groups because the habitat is patchy and changeable, and thus provides an unpredictable food supply (for a similar hypothesis in birds, see ref. 11). If females transfer, however, because variation in the food supply in each group's range has a critical bearing on their fitness, then on finding a 'good' site, they should be expected to resist the entry of others. In this case the number of females present in the group more than doubled between December 1973 and July 1975, yet there was no evidence of serious aggression against newcomers. Moreover, at least 3 females entered during the months of June and July 1974, when food was apparently scarce[7].

Another possibility is that females migrate because the males in harem groups remain for differing lengths of time, and their replacement brings a risk of infanticide, as may be the case in several other primate species[12-15]. During the 5 months after the third male joined the group, the number of infant deaths in relation to the numbers at risk was 3.1 times higher than the average over the whole study. Four out of seven infants present at the time of his entry died, and one emigrated with its mother. Another, born 2 weeks after the replacement, died within a week, after falling from a tree during or just before an unusual fight in which several females gave chase to the male.

In these circumstances, if females were able to assess the ability of a male to hold a harem during the time needed to conceive and rear an infant, they would benefit from choosing among neighbouring males before becoming pregnant and resident with one. The trait would then be expected to spread

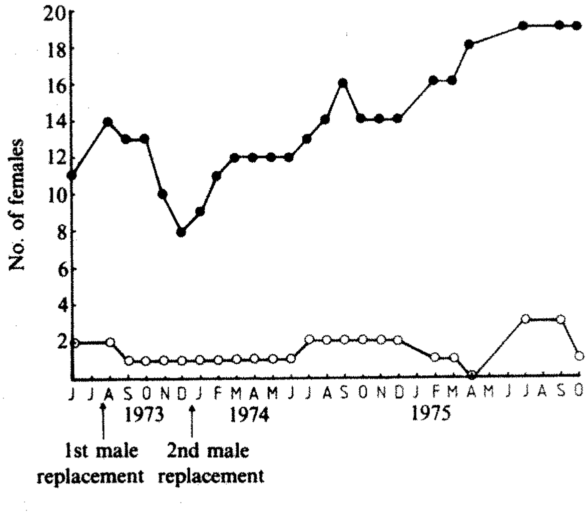

Fig. 1 Variation in the number of females in the Tana study group over 29 months. Also shown is the timing of two male replacements in the group. ●, Adult; ○, subadult.

0028-0836/79/420568—02$01.00

rapidly in the population[16]. Such factors could account for the apparently greater preference by females for the third male in the study group, who was resident for at least 21 months, than for the second who remained for only 5 months. Further study of the problem would include a careful comparison of the behaviour of males to detect cues by which females might discriminate between them.

I am grateful to the Kenya Government for permission to carry out this study and to the New York Zoological Society for finance. I thank Drs M. Kavanagh, J. Oates and T. Struhsaker for discussion and comments.

Captopril (SQ 14225) depresses drinking and aldosterone in rats lacking vasopressin

I. W. Henderson, Annette McKeever & C. J. Kenyon

Department of Zoology, University of Sheffield, Sheffield, UK

Angiotensin II is dipsogenic, and vasopressin (ADH) regulates renal water excretion. Together, these hormones govern overall mammalian water balance[1,2]. The Brattleboro rat with inherited diabetes insipidus (DI) lacks ADH and is therefore a convenient model with which to elucidate mechanisms regulating water metabolism. In the present studies, angiotensin II has also been removed from DI rats by the administration of an inhibitor (captopril, SQ 14225; D-2-methyl-3-mercaptopropanoyl-L-proline) of the enzyme which converts angiotensin I, the relatively inert component of the renin–angiotensin system, to angiotensin II, the biologically active substance[3]. SQ 14225 reduced the drinking rates, and after 6 days lowered peripheral plasma aldosterone concentrations were associated with hyperkalaemia. We conclude that the polydipsia of diabetes insipidus partly results from elevated plasma renin activities and angiotensin II concentrations seen in this syndrome. Further, the apparent hypoaldosteronism of DI Brattleboro rats reflects differences in both tissue usage of the steroid and adrenocortical sensitivities associated with polyuria, hyperosmolarity and possibly potassium wasting[4,5].

DI rats drink approximately eight times more water than normal animals[6,7], and in the present experiments each drank about 80 ml per 100 g body weight per 24 h during the initial 3-day control observation period. When the orally active SQ 14225 was introduced into the water (30 mg l^{-1}), the drinking rates were reduced by about 20% (Fig. 1). Control DI rats with a continuous supply of tap water drank at a consistent daily rate (76.4 ± 1.7 ml per 100 g per 24 h; $n = 5$) over 9 days. The drinking rate was not reduced because rats find SQ 14225 distasteful, as a daily stomach load of water containing the inhibitor lowered drinking rates to a similar extent (unpublished observations).

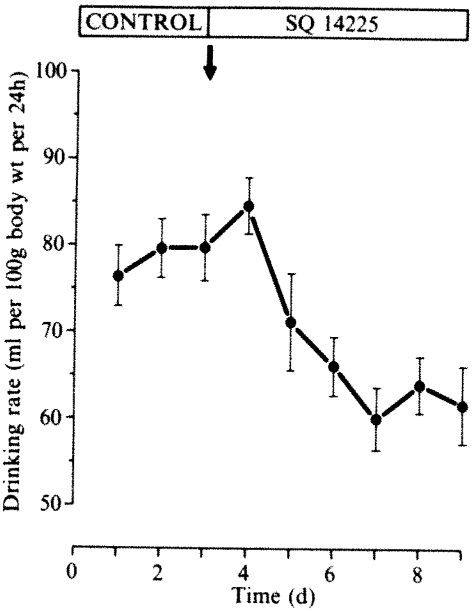

Fig. 1 The effects of SQ 14225 on drinking rate in male DI Brattleboro rats over a 9-day observation period. Rats were isolated for a 3-day adaptation period. Daily water consumption was measured for a further 3-day control period; after this, SQ 14225 was added to the drinking water (30 mg l^{-1}) at (↓), and drinking rates measured for a further 6 days, after which the animals were killed and blood collected. Each point is the mean±s.e. of fluid intake of five rats. Values on days 7, 8 and 9 statistically different at $P < 0.05$. A control group of rats not given the drug at all, gave a drinking rate of 76.4 ± 1.7 ml per 100 g body weight per 24 h. Food intake and growth rates in control and SQ 14225-treated rats were similar.

Peripheral blood was collected from the abdominal aorta under ether anaesthesia on the morning of experimental day 10 (Fig. 1). Plasma osmolarities, sodium and corticosterone concentrations were similar in control and SQ 14225-treated rats (Table 1). Aldosterone concentrations were 66% lower in the SQ 14225-treated rats and plasma potassium concentrations slightly higher than control. Electrolytes were determined by flame photometry, osmolarities by freezing point depression and corticosteroids by radioimmunoassay[8].

Inhibitors of enzymes responsible for the conversion of angiotensin I to angiotensin II have recently been used as potent antihypertensive drugs[9–11]. In particular, those such as SQ 14225 reduced the blood pressure in renal hypertension as well as in hypertension which is free of overt abnormalities in the renin–angiotensin system. Their actions are highly complex, as angiotensin II, in addition to its dipsogenic actions, has feedback relationships with ADH[12], preferentially influences adrenocortical aldosterone biosynthesis, acts on the renal vasculature and has fairly specific roles in regulating blood pressure[2,13].

The severity of the polydipsia and polyuria of diabetes insipidus is attenuated by adrenocortical steroids; water intake and urine production rates fall by 50% after adrenalectomy of DI rats[6]. The present observed reduction in aldosterone concentrations without changes in corticosterone may indicate that the mineralocorticoid itself affects voluntary water intake either by direct actions on dipsogenic centres or indirectly as a result of alterations in sodium appetite and/or potassium balance[14]. The hypoaldosteronism, hypokalaemia and elevated plasma renin activity of DI rats may result from defective renal tubular mechanisms[4], although a possibly increased metabolic clearance rate of aldosterone (R. J. Balment and I.W.H., unpublished observations) could effect similar changes. Indeed, the zona glomerulosa of DI rat adrenals is far more sensitive to angiotensin II than that of non-DI rats[15].

Previous studies indicated that SQ 14225 increased drinking in DI Brattleboro rats[16]; in the same studies angiotensin, rather

surprisingly, decreased drinking. Direct comparison with the present experiments is difficult, however, as the time course was short (2–6 h), whereas the present data suggest that at least 2 days of treatment are required for the depressed water intakes to become apparent, at least in the doses used. Other investigations have shown that SQ 14225 reduces peripheral plasma aldosterone concentrations in both normal and hypertensive patients[17], whereas in deoxycorticosterone acetate–salt hypertensive rats drinking rates are reduced[18].

We thank Dr P. V. Pigott (Squibb Europe) and Dr Z. P. Horovitz (E. R. Squibb & Sons) for the supply of SQ 14225. These studies were in part supported by grants from the SRC.

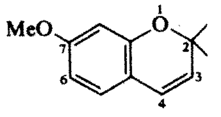
The action of precocenes in milkweed bugs (*Oncopeltus fasciatus*) and locusts (*Locusta migratoria*)

G. T. Brooks, G. E. Pratt & R. C. Jennings

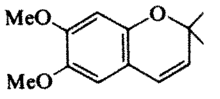
Agricultural Research Council, Unit of Invertebrate Chemistry and Physiology, University of Sussex, Brighton, UK

The active constituents of the plant *Ageratum houstonianum* causing early larval instars of some insects to moult into precocious prothetelic adults are 7-methoxy-2,2-dimethylchromene and 6,7-dimethoxy-2,2-dimethylchromene[1]—precocenes 1 and 2 (P1, P2). P2 causes atrophy of the corpora allata (CA) in at least two species[2–5] and juvenile hormone (JH) production is suppressed, simulating removal of the glands. Active CA are required for the effect of P2 in *Oncopeltus*[5]. The CA are the site of monooxygenase (MO) activity associated with JH biosynthesis[6] and in appropriate conditions, those isolated from certain adult insects can effect the terminal epoxidation of endogenous *E,E*-methylfarnesoate to give C_{16}JH (refs 7, 8). The destructive effect of P2 on the CA, together with the finding[9] that the 3,4-dihydrodiol is a significant metabolite in some insects, suggested that P2 has a specific cytotoxic action within the glands, possibly mediated by local formation of the 3,4-epoxide[10]. Reactive epoxides of polycyclic aromatic hydrocarbons[11], bromobenzene[12], or aflatoxins[13], and oxidative metabolites of other xenobiotics[14] have been implicated in their cytotoxic, mutagenic and/or carcinogenic effects in mammals, in some cases with support from manipulations of the critical balance between activating (oxidising) and deactivating enzymes *in vivo*[12]. We now present evidence that the action of precocenes on immature *Oncopeltus* and *Locusta* requires an oxidative bioactivation within the CA. The generation of reactive metabolites from innocuous precursors in vital tissue, if it can be linked to appropriate species and organ selectivity, offers an attractive approach to insect control.

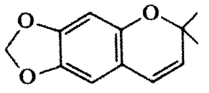
When early second instar *Oncopeltus* were exposed to deposits of various compounds and mixtures in glass jars, P2 at 1 μg cm^{-2} gave total precocious metamorphosis at the 4th instar (Fig. 1), whereas 2H-P2 (compound V, below) had no effect at up to 5 μg cm^{-2}, above which mortality occurred. Thus, the 3,4-double bond is required for biological activity. The methylenedioxyphenyl (1,3-benzodioxole) analogue MDP(III) is also ineffective as an anti-allatin, despite its resemblance to P2 and similar polarity, as attested by an R_F value (TLC on silica gel; solvent, ethyl acetate/xylene, 25:75) lying in the range that includes P1, methylfarnesoate, P2 and C_{16}JH; a relationship which should ensure its reaching the cellular sites, especially those in the CA, that P1 and P2 reach.



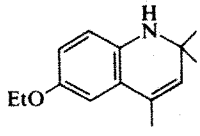
(I) P1*
(IV) 3,4-dihydro(2H-P1)
(VII) 6-methoxy-7H



(II) P2
(V) 3,4-dihydro-(2H-P2)



(III) MDP
(VI) 3,4-dihydro-(2H-MDP)



(VIII) Ethoxyquin

*Compounds except P2 were inactive when tested at 2 μg cm^{-2} as in Fig. 1; P1 is active at 5 μg cm^{-2} upwards.

If an oxidative bioactivation is required for precocenes' action, it is less likely to occur (self-stabilising effect) with MDP, which contains the 1,3-benzodioxole moiety, characteristic[15] of certain insecticide synergists that act by inhibiting MO. Apart from any self-stabilising effect (believed to result in self-antagonism in this case) MDP should also inhibit MO that attack other molecules. Thus, in the cockroach CA bioassay of Pratt and Finney[16], MDP inhibits ($IC_{50} \sim 3 \times 10^{-6}$ M), more effectively than P2 (ref. 17), the epoxidation step in the conversion of exogenous farnesenic acid into C_{16}JH. These considerations make MDP an ideal candidate inhibitor of P2 oxidation in the CA *in vivo* and according to our hypothesis, a likely antagonist of its action. In fact, we find a clear-cut antagonism of P2 action by both MDP (Fig. 1) and its 3,4-dihydro-derivative (2H-MDP; VI) in *Oncopeltus*; normal moulting is restored at

0028-0836/79/420570—03$01.00

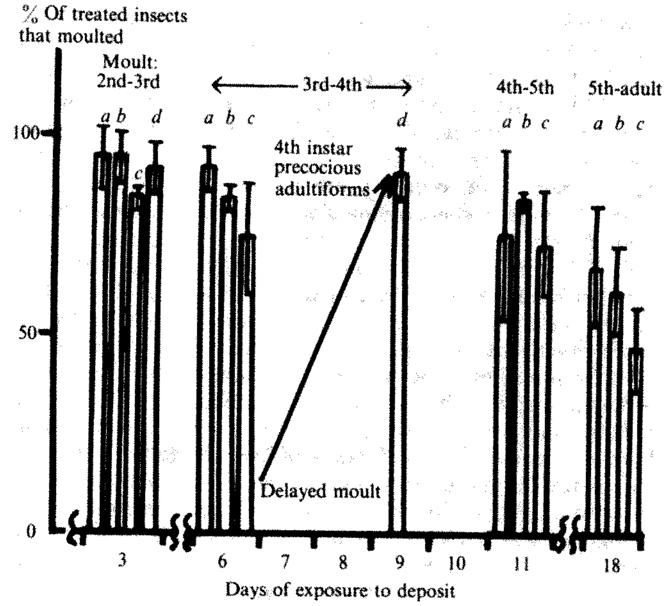


Fig. 1 Groups of 20 early 2nd instar *Oncopeltus* were confined (27°C; 2:1 light/dark regime) in 100 cm^2 glass jars (two groups per treatment) containing milkweed seed and water and surface treated with *a*, impregnating solvent (ether/acetone) only; *b*, MDP only (2 $\mu g\ cm^{-2}$); *c*, MDP (2 $\mu g\ cm^{-2}$) plus P2 (1 $\mu g\ cm^{-2}$); or *d*, P2 only (1 $\mu g\ cm^{-2}$). Except for P2 at the moult 3–4, values (mean of two experiments with range) represent insects in each exposure that moulted normally; others died. With P2 alone (*d*), the normal moult 2–3 is followed by delayed moulting (arrow) to either permanent or short-lived precocious 4th instar adultiforms between days 6–9. When MDP (2 $\mu g\ cm^{-2}$) is co-formulated with P2 (*c*), the normal 3–4 (day 6), 4–5 (day 11) and 5–adult moults are restored.

the 4th and 5th instar with MDP plus P2 (columns *c* in Fig. 1). In some experiments an increased number of deaths (compared with controls) as 5th instar larvae or during the adult moult, indicates a previously noted[18] deleterious effect of P2 at the final moult which is probably unrelated to the anti-allatal effect. However, normal adults arising from antagonism tests with both MDP and 2H-MDP laid eggs that produced viable larvae. MDP showed no JH-activity towards *Oncopeltus* continuously exposed from the late 4th stage to 5 $\mu g\ cm^{-2}$ in the jar deposit test, or when topically applied (400 μg) in acetone to early 5th instar *Locusta*, or (40 μg) to newly moulted pupae of *Tenebrio molitor*.

Compounds such as 2,3-methylenedioxynaphthalene and 2,4,5-trichloropropargyloxybenzene, recognised as 'insecticide synergist' type MO inhibitors[15] gave indications of antagonism with P2 but closer analogues such as P1, 2H–P1 (IV), the P1-isomer(VII), 2H-P2 (V) and the antioxidant ethoxyquin which might inhibit P2 metabolism competitively, had no effect on its action. Thus, efficient antagonists must apparently bear a close structural resemblance to the precocenes and also interact strongly with the oxidase(s) concerned, in the manner of classical insecticide synergists. Sesamex, a JH-mimic for *Oncopeltus*[19], had no apparent effect on development as a 2$\mu g\ cm^{-2}$ deposit but showed partial antagonism in co-formulation with P2; neither peanut oil, liquid paraffin, tocopherol or tocopherol acetate protected against P2 at the 2:1 ratio, thereby eliminating the possibility of a diluent effect in jar deposits. Although sesamex might antagonise P2 action both by inhibiting MO and/or replacing JH, the antagonism is clearly incomplete in these experimental conditions, in contrast to that shown by MDP or 2H-MDP. Neither piperonyl butoxide nor tropital prevented precocious metamorphosis in these experiments.

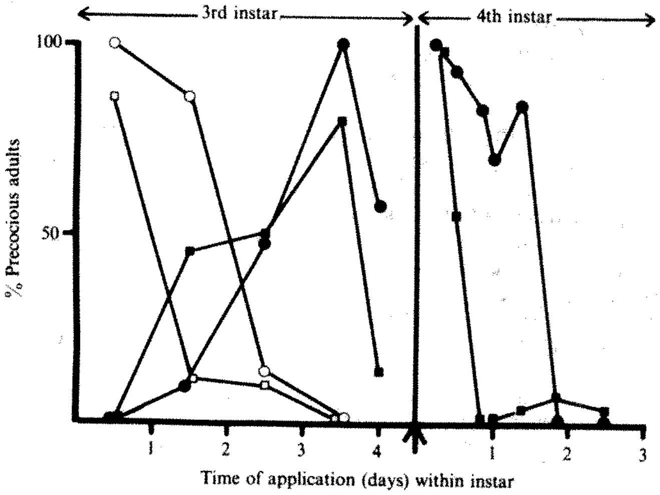

Fig. 2 Periods of sensitivity to the prothetelogenic action of precocene 1, during the 3rd and 4th instars of *Locusta*. We topically applied 50 μg (squares) or 100 μg (circles), in acetone (5 μl), to groups of 10 or 20 larvae at different times during development and recorded the percentage of animals exhibiting precocious metamorphosis at a subsequent ecdysis: hollow symbol, precocious 4th instars; solid symbols, precocious 5th instars. Solvent controls gave only normal animals.

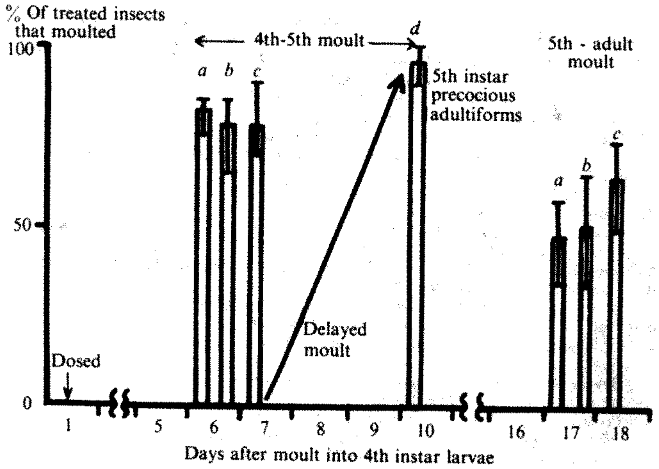

Fig. 3 Groups of 20 recently moulted 4th instar *Locusta* were topically treated with acetone (10 μl) alone, or containing 200 μg of MDP. After 1 h, insects were further treated with acetone (10 μl), alone, or containing P2 (100 μg), to give *a*, solvent control; *b*, MDP only; *c*, MDP/P2 (2:1); and *d*, P2 only test groups which were fed and held in a light/dark (2:1; 40°/25°C) regimen. Values (mean of three experiments with range) represent survival at each moult; precocious 5th instar larvae were not found in *c*, nor normal 5th instars in *d*. The slow moult (arrow) into permanent precocious 5th adultiforms between days 7 and 10 with P2, is prevented by the combined treatment (columns *c*), which gives normal 5th instars and adults.

P1[20] and P2[3,21] cause precocious metamorphosis in *Locusta* and we determined periods of optimal sensitivity to them, as in Fig. 2, which shows that treatment with P1 is effective throughout the 3rd and early in the 4th instar. Whereas P1 and P2 were fully effective at 100 μg when topically applied to early 4th instar larvae, neither 2H-P1 nor 2H-P2 caused precocious metamorphosis at doses up to 400 μg per insect, beyond which toxic effects appeared. As with *Oncopeltus*, the 3,4-double bond seems to be necessary for activity. MDP (200 μg) topically applied 1 h before either compound prevented the effect of 100 μg of P1 or P2. In Fig. 3, P2 applied alone delayed the moult from 4th to 5th instar and produced permanent precocious 5th adultiforms (column *d*), whereas normal 5th instar larvae and adults resulted from the MDP/P2 combination (columns *c*).

Groups of five 4th instar *Locusta*, treated with P2 or MDP/P2 as in Fig. 3, were surface rinsed with ether/acetone (4:1) and the carcasses extracted with this solvent, 3 h after application of P2. Quantitation by GLC showed that up to three times more P2 remained in the insect tissues when MDP was also present, demonstrating that this 1,3-benzodioxole analogue indeed inhibits the oxidative metabolism of P2. MDP can evidently maintain its protective effect within the CA, despite the possibility that more unmetabolised P2 arrives there because of the inhibition of its metabolism in peripheral tissues. Similar effects were observed in studies on the pharmacokinetics of 4-ipomeanol, a toxin that acts on mammalian lung by oxidative metabolism[22].

Earlier work[17] showed that P2 progressively inhibited the final steps, including epoxidation, of C_{16}JH formation from farnesenic acid in the CA of the cockroach, *Periplaneta americana, in vitro*. Further experiments are in progress to test our hypothesis that labile precocene 3,4-epoxides, or derivatives thereof, are proximate insect- and cell-specific cytotoxins (alkylating agents) whose formation in competition with the epoxidation step of JH biosynthesis in the CA of sensitive insects destroys the glands' ability to synthesise the hormone.

We thank D. W. Mace, Mrs. S. Saunders, Dr A. P. Ottridge and colleagues of the insectary staff for their assistance.

Cell size changes in undeprived laminae of monkey lateral geniculate nucleus after monocular closure

M. P. Headon, J. J. Sloper, R. W. Hiorns & T. P. S. Powell

Departments of Human Anatomy and Biomathematics, Oxford, UK

Transneuronal degeneration in the lateral geniculate nucleus (LGN) due to removal of an eye or closure of the eyelids has traditionally been measured by comparing the sizes of cells in the deprived laminae with those of the corresponding undeprived laminae in the nucleus of the opposite side of the same brain. However, the undeprived laminae may themselves change; some hypertrophy of their cells has been found in kittens following early monocular closure[1] but such comparisons are difficult in the cat because of the variation between animals[2]. In a recent study of the effect of binocular closure in the monkey[3] it was necessary to measure cell sizes in the LGNs of a series of normal monkeys as controls, because there are no undeprived laminae after binocular closure. From this series of normal animals it was apparent that there is much less variation between individual monkeys than has been found with cats and it was thus possible to make reliable comparison of cell sizes between different animals. In the present study the series of normal monkeys has been extended and the mean cell size and its variability between animals have been established for each geniculate lamina in the normal rhesus monkey. We give here a comparison of the cell sizes of both deprived and undeprived laminae following monocular eyelid closure with normal measurements and report some unexpected findings, particularly in animals where monocular closure has been carried out relatively late.

Eight normal monkeys formed the control group, five which were perfused at 8, 9, 17, 32 and 32 days of age and three young adults. In six more animals the lids over one eye were sutured under open ether anaesthesia at various ages and the young monkeys returned to the mother for various periods (Fig. 1). As both these variables have been found to be important the results have been analysed in two groups: early closure, long survival (2) and late closure (4). Details of the methods of fixation, histological preparation and measurement have been described previously[3]. Fifty cells were measured in each lamina of each animal and the sample was taken from the middle of the lateral limb at the junction of the middle and posterior thirds of the nucleus; only cells with distinct nucleoli were drawn. To make comparisons between animals the mean cell area for each lamina in each animal has been treated as a single observation and the averages of all the means and standard deviations of these values have been calculated from these for each group (Tables 1–3).

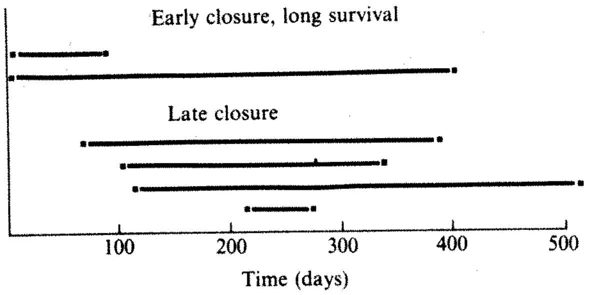

Fig. 1 The age at monocular closure and duration of closure for animals in this study.

Comparisons between groups have then been made for each lamina using Student's *t*-test. Values from the left and right sides of control animals have been treated separately throughout as have the deprived and undeprived laminae of experimental animals. In addition, for each lamina of the normal animals, the range within which 95% of the mean cell areas for a single normal lamina would be expected to fall has been calculated so that individual experimental animals may also be compared with the normal group.

Analysis of the cell area measurements for each lamina in the eight normal animals shows the degree of variability between animals; individual details of five have been published[3] and the small variability of the means from each animal about the group means can be seen from the small standard deviations of the normal measurements (Table 1). The variability in the parvocellular laminae (III to VI) is considerably less than in the magnocellular laminae (I and II). Comparison of the five infants with the three adults shows little or no growth occurring in the

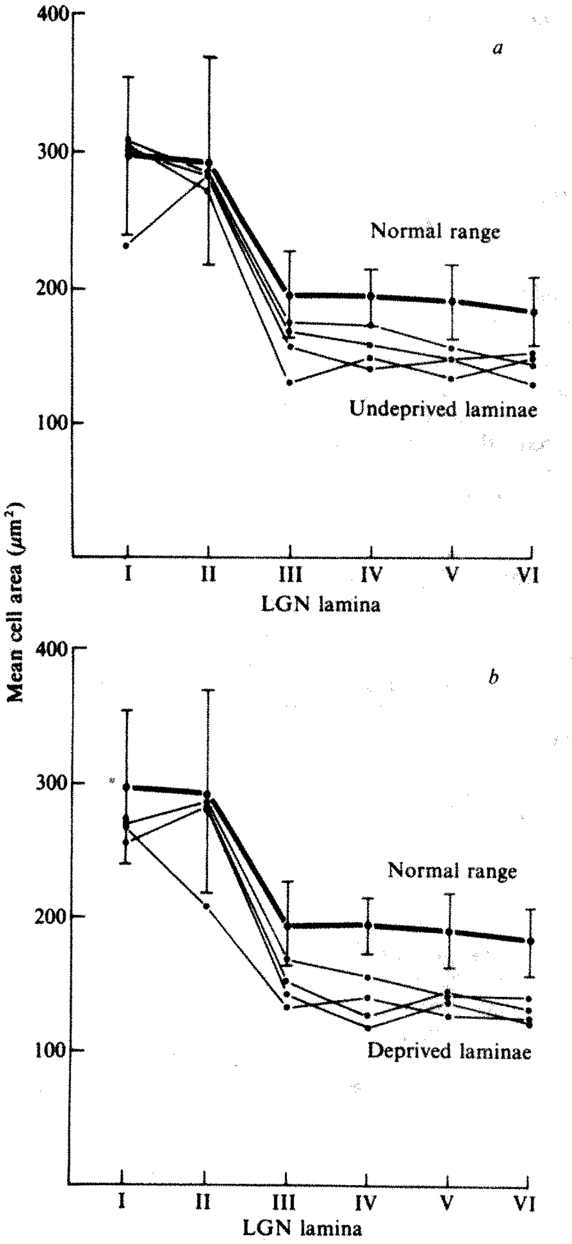

Fig. 2 Mean areas of neuronal somata in the undeprived LGN laminae (*a*) and deprived laminae (*b*) of four monkeys following late monocular closure. Lines join the measurements for an individual animal. Each bar for the normal range indicates an interval within which the mean cell area in a single lamina from one animal may be expected to lie with a probability of 0.95. Most of the values for both the deprived and undeprived parvocellular laminae fall below the normal range indicating shrinkage of cells in these laminae.

parvocellular laminae within the ages studied but there is a little growth in the magnocellular laminae. Measurements of all eight normal animals have therefore been pooled to determine the mean and variability of each lamina in the normal monkey. This variability is much less than that of 'normal' laminae in monocularly deprived animals.

The measurements in the four monkeys with late monocular closures show little shrinkage when the deprived laminae are compared with the undeprived laminae (Table 2). This would be interpreted as showing the decline in sensitivity towards the end of the critical period. However, if these measurements are compared lamina by lamina with those of the normal animals, there is a 20–25% shrinkage of the *undeprived* parvocellular laminae and this is masking a shrinkage of ~30% in the deprived parvocellular laminae (Table 2, Fig. 2). The undeprived magnocellular laminae do not show a comparable effect and the shrinkage of the deprived magnocellular laminae is much less than that of the deprived parvocellular laminae. The differences between deprived and undeprived cell sizes after monocular eyelid closure are thus very similar for the magnocellular and parvocellular laminae. Late monocular closure thus causes a marked shrinkage of the parvocellular laminae but it affects both deprived and undeprived laminae to almost the same extent.

Table 3 shows the mean measurements for the two monkeys with early closure and long survival. Comparison of deprived with undeprived laminae shows shrinkages of 20–30%, in agreement with previous reports. However, if the measurements are compared with those of the normal animals it is apparent that there is a consistent shrinkage of ~10% in the undeprived parvocellular laminae. This means that the shrinkage in the deprived laminae is underestimated by this amount in the traditional method.

As the undeprived magnocellular laminae show little change they form an internal control for the changes in the parvocellular laminae. This may be measured by calculating the ratio of the mean cell area of the magnocellular laminae to that of the parvocellular laminae, taking deprived and undeprived laminae separately. Table 4 shows these ratios for each animal and that the ratio is consistently higher following monocular closure for both deprived and undeprived laminae. In any one animal the ratio changes for deprived and undeprived laminae are remarkably similar, although the mean cell areas from which they are calculated may differ markedly; this indicates that the excess shrinkage of the deprived parvocellular laminae compared with the deprived magnocellular laminae is closely similar to the shrinkage of the undeprived parvocellular laminae compared with the undeprived magnocellular laminae. As well as the generally accepted shrinkage of the deprived laminae in relation to the undeprived laminae following late monocular closure there is thus an additional and larger shrinkage affecting both deprived and undeprived parvocellular laminae equally. The early closure, long survival group shows a similar but smaller shrinkage of the undeprived parvocellular laminae (although the survival periods were comparable in the two groups), indicating

that this effect increases with age at monocular closure within the age limits of the study.

We suggest, therefore, that the development of the primate visual system occurs in two major phases. Initially the anatomical balance between the connections of the two eyes is established, corresponding to the critical period as presently defined and the period of plasticity of the cortical ocular dominance columns[4,5]; it is during this period that monocular closure may produce hypertrophy[1]. As these connections become established we suggest that the presence of synchronous inputs from the two eyes becomes necessary for the establishment of normal binocularity in the cortex. In the absence of corresonding visual inputs it is no longer possible for both eyes to drive the same cell effectively simultaneously and so the connections from the two eyes interfere with each other and the development of both is inhibited. This interference thus differs from the competition described in the cat during the critical period[6].

$* = P < 0.001$.

Three major conclusions may be drawn by comparing the results of monocular closure with those of normal monkeys. First, following late monocular closure or early closure and a long survival period there is shrinkage of the undeprived parvocellular laminae; this leads to underestimation of the degree of shrinkage of the deprived parvocellular laminae if the undeprived laminae are used as a control. The primate visual system is thus more sensitive to monocular closure in older animals than had previously been supposed, with increasing effect on the undeprived laminae. Second, as this effect is restricted to the parvocellular laminae which represent the X-cell system while the magnocellular laminae represent the Y-cell system, these two functional pathways react differently to monocular deprivation. Third, as the cell areas measured in the late closure group for all the deprived laminae and the undeprived parvocellular laminae are smaller than those in normal animals at the corresponding ages of closure it can be concluded in this group at least that actual shrinkage of cells has taken place rather than failure of growth.

Axonal transport of vasoactive intestinal peptide in sciatic nerve

Antonio Giachetti & Sami I. Said

Departments of Pharmacology and Internal Medicine, University of Texas Southwestern Medical School, Dallas and Veterans Administration Medical Center, Dallas, Texas 75235

Dense plexuses of neurones containing immunoreactive vasoactive intestinal peptide (VIP) have been found in discrete areas of the central nervous system and in peripheral organs, including the gastrointestinal tract, pancreas and urogenital system[1–7]. In many of these locations VIP is concentrated in nerve endings, where it can be released by high K^+ concentrations in a Ca^{2+}-dependent manner[8,9]. VIP release may also be provoked by electrical stimulation of nerves, for example the vagus[10]. VIP thus shows some of the features of neurotransmitter or neuromodulator substances. The presence of immunoreactive VIP in the fine terminal varicosities as well as in the cell bodies of neurones[4,11] suggests that it might be transported from the perikaryon, where it is presumably formed, to the nerve endings, through the axonal transport system[12–14]. Such transport would be in keeping with a role for the peptide as a neurohumor or neurohormone[15]. We report here that VIP accumulates in constricted rat sciatic nerves in a manner suggesting fast, anterograde axonal flow.

Under light ether anaesthesia, the left sciatic nerve in male Sprague–Dawley rats was constricted by tying a silk thread around the nerve below the hip. The contralateral nerve was isolated but not ligated. After 4, 12, 24 or 72 h, the rats were killed by decapitation. The dissected sciatic nerves were cut in consecutive segments (0.5 cm each), beginning with the segment immediately proximal to the ligature. Two or three identical segments from different experiments were pooled, homogenised in 1 ml of ice-cold acetic acid (0.2 M); the homogenates were centrifuged at 8,000 *g* for 20 min and the supernatants were analysed for immunoreactive VIP by a sensitive and specific radioimmunoassay[16]. In four further experiments, the left sciatic nerve was ligated at two points, 1 cm apart; the segment between the two ligatures as well as an equal segment distal to

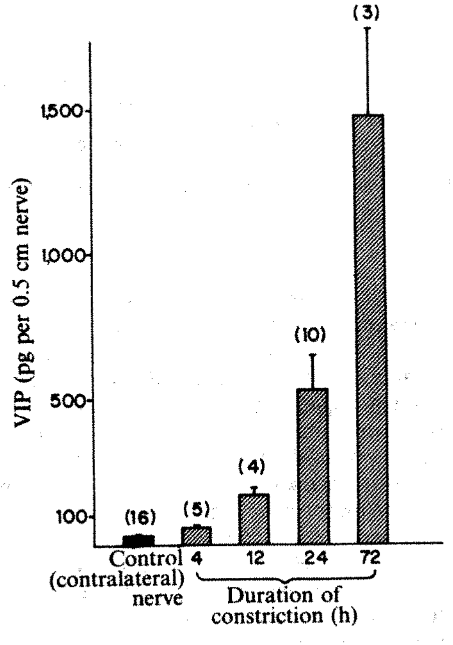

Fig. 1 Accumulation of VIP in proximal segment of sciatic nerve constricted for 4, 12, 24 or 72 h. Values are means ± s.e.m. Number of determinations in parentheses.

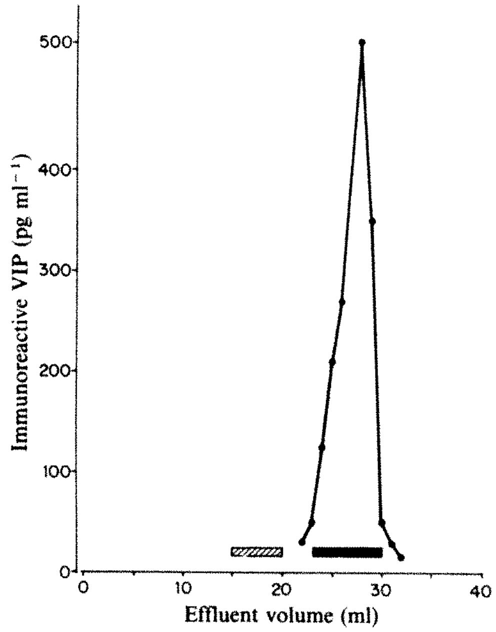

Fig. 2 Chromatogram of VIP immunoreactivity in an extract of sciatic nerves (402 mg) on a column of Sephadex G-25 Fine (0.9 × 60 cm). The nerves had been homogenised in 25 ml 0.2 M acetic acid, the homogenate centrifuged, and the supernate lyophilised and reconstituted in 0.5 ml of 0.2 M acetic acid. The column was calibrated with ^{125}I-labelled porcine VIP (solid bar) and ^{125}I-labelled albumin (shaded bar). Eluant, 0.2 M acetic acid; flow rate, 12 ml h^{-1}; fraction vol., 1 ml.

the second ligature were homogenised and assayed for VIP content.

In the control (unligated) nerve, VIP content was uniform in all segments examined and averaged 32 ± 5 pg per segment. At all intervals after nerve constriction, the concentration of immunoreactive VIP increased significantly ($P < 0.025$) in the segment just proximal to the ligature. The peptide levels increased with the duration of constriction (Fig. 1), reaching 17 and 46 times the control value after 24 and 72 h, respectively. Accumulation of the peptide occurred only in the segments proximal to the constriction (Table 1), and peptide levels decreased abruptly above the first segment (0–0.5 cm). VIP content also remained low in the segment below a second constriction (14 pg), and in the segment between two ligatures (24 pg).

On chromatography of extracts of sciatic nerves on a column of Sephadex G-25 Fine, immunoreactive VIP was eluted in one peak. The location of this peak was identical for ligated (12–72 h) and unligated nerves, and coincided with the peak of ^{125}I-labelled VIP chromatographed in the same conditions (Fig. 2). These chromatographic data suggest the presence of one molecular species of the peptide in ligated or unligated sciatic nerves.

The findings indicate axonal transport of VIP along the sciatic nerve predominantly in a proximal-to-distal direction. The absence of a concentration gradient of VIP along the contralateral nerve or in the constricted nerve more proximal to the segment immediately above the ligature suggests that the peptide is not formed *in loco*, but is probably synthesised in neuronal cell bodies and transported along the axon toward the nerve endings.

Table 1 Concentration of immunoreactive VIP in 0.5-cm segments of sciatic nerve proximal to constriction for 24 h

Segment	VIP (pg per nerve segment)
0–0.5	527 ± 117 (10)
0.5–1.0	65 ± 10 (10)
1.0–1.5	102 ± 8 (5)
1.5–2.0	103 ± 6 (5)

VIP values are means ± s.e.m. Number of determinations are in parentheses.

The rate of axonal transport of VIP (in mm h^{-1}) could be computed as: $(C - C_c/T)/(C_c/S)$, where C and C_c are the concentrations of the peptide above a constriction and in the contralateral nerve, respectively, T is the duration of constriction (in h), and S is the length of the nerve segment (in mm). From the data after 24 or 72 h constriction, the velocity of axonal transport of VIP was 3.3 mm h^{-1}. This velocity is typical of the relatively fast axoplasmic transport rates reported for cholinesterase in frog sciatic nerve[17], for certain polypeptides synthesised in rabbit retinal ganglion cells[18] and for other systems[19].

Axonal transport of peptides has previously been documented for oxytocin and vasopressin in the hypothalamo–neurohypophysial system[20–22]. Our results now show that neuronal peptides can travel by axonal transport in peripheral nerves as well. The demonstration of axoplasmic flow of VIP supports the notion that this peptide may function as a neurotransmitter or neuromodulator in peripheral nerves.

GABA of CNS origin in the rat anterior pituitary inhibits prolactin secretion

G. Racagni*, J. A. Apud*, V. Locatelli†, D. Cocchi†, G. Nistico'‡, R. M. di Giorgio‡ & E. E. Müller§

§ Institute of Pharmacology and Pharmacognosy, University of Cagliari, Italy

Hypothalamic hormones synthesised in nuclei within the medial basal hypothalamus (MBH) and extrahypothalamic regions and released from nerve endings at the level of the median eminence (ME) into the hypophysial portal capillary system control anterior pituitary (AP) function[1]. The median eminence is a key area for neuroendocrine regulation as it receives projections of neurotransmitter pathways which modulate functions such as

0028-0836/79/420575—04$01.00

synthesis and release of hypothalamic hormones[2]. In addition, transmitters released from the ME into the stalk portal blood may act directly at the AP level to control hormone secretion—this has been demonstrated for dopamine (DA) with respect to prolactin (PRL) secretion[3] and it has been suggested that DA itself may represent the so far elusive PRL-inhibiting factor (PIF)[2,4,5]. Recently, evidence has been presented which suggests that γ-aminobutyric acid (GABA) may also have an important inhibitory role in regulating PRL secretion in the rat. Both GABA and muscimol, a powerful agonist at GABA receptors[6], inhibited PRL secretion when injected into urethane anaesthetised female[7] or freely moving male rats[8]. In view of the poor penetrability of the blood-brain barrier (BBB) by both amino acids[9] and the recently described specific GABA receptor sites in rat AP[10], the above data support the notion that GABA may act directly at the level of the AP to inhibit PRL secretion. This proposition is reinforced by the demonstration that both GABA[11] and muscimol[12] inhibit PRL secretion from rat isolated APs, an effect which is blocked by the antagonist picrotoxin. We report here that GABA, derived from the central nervous sytem (CNS), is present in the rat anterior pituitary, and we provide evidence that GABA has a functional role in the control of PRL secretion.

Male Sprague–Dawley rats (150–200 g) were killed by microwave radiation and their GABA content in the anterior and posterior pituitary lobes was determined by a mass-fragmentographic technique[13] and compared with DA titres in the same tissues.

Table 1 shows that GABA is present in both the anterior and posterior lobes of the pituitary, the concentration of the amino acid being 7–8 times greater in the latter than the former tissue. DA shows a similar pattern of distribution in the pituitary, although absolute levels of the amine in both tissues are consistently lower than those of the amino acid.

Endogenous GABA in the brain is synthesised almost exclusively by decarboxylation of glutamic acid by glutamic acid decarboxylase (GAD)[14] and GABA is degraded by a transamination catalysed by α-ketoglutarate-GABA transaminase (GABA-T)[15]. It is evident from Table 1 that the AP, despite the presence of GABA, does not contain the GABA biosynthetic machinery; no GAD activity was detectable at this level whereas GAD activity was present in the hypothalamus and, although at low levels, also in the posterior lobe. This finding is analogous to the finding that DA is present in the AP even though its biosynthetic enzyme, tyrosine hydroxylase cannot be detected[16]. A further similarity between GABA and DA at AP level is the fact that for both the amino acid transmitter and the amine, the physiological catabolic enzymes, that is, GABA-T (Table 1) and monoamine oxidase[16] respectively, are present in the glandular tissue. GABA-T activity was also detected in the hypothalamus at concentrations similar to those found in the AP (Table 1).

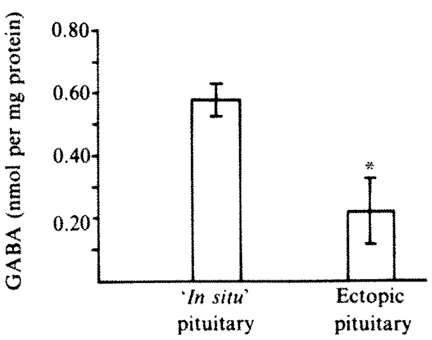

Fig. 1 GABA concentration in the ectopic or in *situ* anterior pituitary gland. Female Sprague–Dawley rats (100–130 g) were hypophysectomised by the transauricular route[36] and 15 days later received implants of one anterior pituitary, obtained from an intact female littermate, under the kidney capsule. After transplantation and before the experiments, animals were weighed daily; only animals which showed a constant body weight increase throughout this period were included in these studies. GABA concentrations were determined in the ectopic gland 10 days after transplantation (ref. 13). Age- and weight-matched female rats served as controls. Significance of differences between groups was calculated by Student's *t*-test. Values represent the mean + s.e.m. of six determinations. $^*P < 0.01$.

Taken together these findings argue against the possibility of local formation of GABA in the AP and suggest instead that the gland may merely be a tissue for storage and catabolism of GABA manufactured elsewhere.

Ethanolamine-*O*-sulphate (EOS), a structurally related analogue of GABA, is a potent, specific, competitive and irreversible catalytic inhibitor of GABA-T *in vitro* and *in vivo*[17]. Experiments were performed to determine whether GABA stored in the AP originated in the CNS. Table 2 shows that EOS injected intracerebroventricularly (i.v.t.) at 2 mg per kg bodyweight into the lateral ventricle of freely behaving unanaesthetised rats induced an increase in GABA content not only in the hypothalamus but also in the anterior and posterior pituitary

Table 1 GABA concentrations and GAD and GABA-T activities in rat pituitary lobes and hypothalamus

Tissue	GABA (nmol per mg protein)	GAD (pmol CO_2 per mg protein per h)	GABA-T (nmol glutamate per mg protein per h)	Dopamine (pmol per mg protein)
Anterior lobe	0.76 ± 0.07	None	324.6 ± 21.1	1.25 ± 0.13
Posterior lobe	5.53 ± 0.60	0.574 ± 0.017	245.2 ± 21.2	53.71 ± 10.01
Hypothalamus	40.11 ± 3.81	6,320 ± 450	224.7 ± 17.0	66.63 ± 3.22

To avoid variability due to circadian fluctuations of GABA content in the hypothalamus[28], these and the following experiments (Tables 2, 3 and Fig. 1) were conducted in the early afternoon. The brain and pituitaries from microwave-radiated (2.0 kW; 2.45 GH; 75 W cm^{-2})[29] male Sprague–Dawley rats were rapidly removed, and the hypothalamus was dissected from the brain according to the procedure described in ref. 30. The weight of an hypothalamic fragment was about 20–25 mg. Pituitaries once removed were washed in cold saline and posterior and intermediate lobes were entirely removed from the isthmus to assure separate analysis of pure anterior and posterior (neural and intermediate) lobes. The mean weight of an anterior or posterior pituitary expressed as mg protein was about 0.5 or 0.1, respectively. For GABA determination, excised hypothalami and pituitary lobes were immediately frozen in dry ice, and then homogenised in 0.1 M formic acid (1 ml for hypothalamus and 200 μl for pituitary lobes) containing the internal standard 4-aminovaleric acid (2 μmol ml^{-1}). The homogenates were centrifuged at 15,000*g* for 20 min and an aliquot of the supernatant was transferred and evaporated under reduced pressure. A mixture of SIL PREP and BSTFA (3 : 1) (Applied Science, Lab. Inc. State College, Bellefonte, Pen.) was added. After incubation for 2 h at room temperature, an aliquot of the reaction mixture was injected into a gas chromatograph–mass spectrometer (Finnigan 3000 E), focused on *m/e* 304 and 174 for GABA-TMS derivative and *m/e* 304 for the internal standard according to Cattabeni *et al.*[13]. DA was also analysed with a mass fragmentographic technique, as described by Cattabeni *et al.*[31]. GAD was assayed by measuring the evolution of $^{14}CO_2$ from L[1-^{14}C]glutamic acid in anaerobic conditions[32]. The $^{14}CO_2$ formed was absorbed in hyamine solution and counted in a liquid scintillation counter. In a typical assay, the incubation vessel contained 0.1 ml of 0.208 M glutamic acid (0.74 μCi L[1-^{14}C]glutamate) in 0.1 M K_3PO_4 buffer containing 0.2 mM pyridoxal phosphate (PLP) *p*H 7.2. The reaction was started by injecting 1 ml enzyme solution in 50 mM K_3PO4 buffer, *p*H 7.2, containing 0.2 mM PP and 1 mM AET (standard buffer) into the incubation vessel. The incubation was performed in a Dubnoff metabolic incubator for 30 min at 37 °C at approximately 150 r.p.m. and was terminated by injecting 0.1 ml of 4 M H_2SO_4 into the reaction mixture. To ensure complete release of CO_2 and absorption in the hyamine base, vessels were incubated for additional 60 min. GABA-T activity was assayed according to Macaione[33] in 100 μl of the reaction mixture containing: GABA, 5 μM; α-ketoglutarate, 5 μM; PLP, 0.4 μM; 0.1 M phosphate buffer, *p*H 7.4 and homogenate (w/v1 : 10). After 1 h incubation at 37 °C, the reaction was stopped by adding 0.4 ml of absolute ethanol. Controls were carried out by adding homogenate after ethanol. GABA content in the homogenate and glutamic acid formed by GABA-T activity were quantitated by means of an amino acid analyser (Carlo Erba). Proteins were determined by the procedure of Lowry *et al.*[34]. For GABA and DA, values represent the mean ± s.e.m. of at least five determinations; for GAD in the pituitary lobes and hypothalamus, values represent the mean ± s.e.m. of five determinations obtained from a pool of 10 glands or 4 hypothalamic fragments, respectively; for GABA-T in the AP and hypothalamus, values represent the mean ± s.e.m. of 6 determinations obtained from 12 tissue samples.

lobes. In the AP the increase in GABA concentration was time related. EOS does not cross the BBB[17] so it is unlikely that these changes are caused by an effect of the drug on GABA catabolism in the systemic circulation. Supporting this view is the observation that intravenous injection of EOS, at a dose 25 times greater than the i.v.t.-injected dose, that is, 50 mg per kg, did not alter GABA concentrations either in the hypothalamus or the pituitary gland (Table 2).

If, as implied by experiments with EOS, the main source of GABA in the AP is via transport of the amino acid from the CNS to the pituitary, location of the pituitary in a site far removed from the sella turcica should result in a lowering of the pituitary concentration of the amino acid. Figure 1 shows that in a gland transplanted under the kidney capsule, the GABA concentration is three times lower than in the pituitary gland *in situ*.

Table 2 GABA levels in rat pituitary gland and hypothalamus after central or systemic administration of ethanolamine-*O*-sulphate (EOS)

	GABA (nmol per mg protein)		
Treatment	Anterior lobe	Posterior lobe	Hypothalamus
Central route			
Saline 10 μl per rat	0.64 ± 0.07	6.05 ± 1.26	48.21 ± 5.40
EOS (2 h)	1.27 ± 0.35*	13.18 ± 3.31*	120.65 ± 15.61*
EOS (4 h)	3.17 ± 0.87*†	19.32 ± 4.97*	150.41 ± 24.50*
Systemic route			
Saline 0.5 ml per rat	0.71 ± 0.18	4.28 ± 1.10	40.11 ± 3.81
EOS (2 h)	0.59 ± 0.20	4.32 ± 1.67	41.33 ± 4.03
EOS (4 h)	0.60 ± 0.17	5.47 ± 1.91	39.67 ± 3.63

In the central experiments, male Sprague–Dawley rats (200–220 g) had a cannula implanted into the lateral ventricle of the brain[35] while under barbiturate anaesthesia. After allowing 2–3 days for recovery, EOS (2 mg per kg in 10 μl saline) was slowly infused through the implanted cannula. When EOS was injected by systemic route, an intravenous (i.v.) dose of 50 mg per kg was used. Animals were killed by microwave radiations 2 and 4 h after EOS administration. Tissues were dissected and assayed for GABA as described in Table 1 legend (ref. 13). Values represent the mean ± s.e.m. of 10 determinations (pooled data of two separate experiments). Significance of difference between groups was calculated by Student's *t*-test.

*$P < 0.01$ versus saline-injected rats;

†$P < 0.01$ versus EOS-injected rats (2 h).

Proof that GABA, probably derived from the CNS and transported into stalk blood to the AP, exerts a functional role in the control of PRL secretion is provided by the experiments summarised in Tables 3 and 4. Table 3 shows that, concomitant with an increase in hypothalamic content of GABA by i.v.t.-injected EOS, there was a clear-cut decrease in plasma concentration of PRL; in contrast, EOS administered systemically affected neither hypothalamic GABA concentrations nor plasma PRL titres. The case for a causal relationship between changes induced in the hypothalamic and pituitary concentrations of GABA and changes in PRL release is strengthened by the observation that they occurred independently of alterations in DA function. In fact, i.v.t. administration of 2 mg per kg EOS, which induced clear-cut rises in GABA concentrations in the hypothalamus and the pituitary, did not affect the DA level in the AP, which is a reliable marker of tubero-infundibular DA function[18] (2.5 ± 1.03 and 2.9 ± 0.35 pmol per mg protein in saline- and EOS-injected rats, respectively). Furthermore, central administration of EOS antagonised the PRL-releasing effect evoked by blockade of DA receptors with domperidone, a drug which, being unable to cross the BBB[19,20], acts almost exclusively at the AP level (Table 4).

Although GABA is a neurotransmitter involved in the control of AP hormone secretion[2], the mechanism(s) underlying its neuroendocrine effects have yet to be clearly established. For instance conflicting data have been presented, indicating both a stimulatory[21–23] and, an inhibitory[7,8,12,24] role for GABA in the regulation of PRL secretion. The data presented here show GABA to be present in the AP gland and offer a plausible explanation for the mechanism underlying the PRL-lowering effect of the amino acid.

Table 3 Prolactin concentrations in the plasma and GABA content in the hypothalamus after i.v.t. or i.v. administration of EOS

	Prolactin (ng ml^{-1})		GABA (nmol per mg protein)	
Treatment	EOS (2 mg per kg) central route	EOS (50 mg per kg) systemic route	EOS (2 mg per kg) central route	EOS (50 mg per kg) systemic route
Saline	20.5 ± 5.5	14.6 ± 3.5	40.01 ± 2.13	45.50 ± 2.60
EOS (2 h)	3.0 ± 0.9*	17.1 ± 1.9	138.99 ± 13.60*	40.20 ± 4.09
EOS (4 h)	9.5 ± 4.2*	15.4 ± 2.4	161.18 ± 24.11*	38.90 ± 3.90

In these experiments central and systemic administration of EOS were performed following the schedule described in the legend to Table 2. Immediately before and 2 and 4 h after EOS administration, male rats were sampled by the retroorbital venous technique[37] for PRL determination in the plasma. PRL was determined by a double antibody radioimmunoassay (RIA), using the method of Niswender *et al.*[38]. All results were expressed in ng ml^{-1} in terms of the NIH standard rat PRL-RP-1, whose potency is 11.0 IU mg^{-1}. The sensitivity of the PRL assay is 1.0 ng ml^{-1}; intra-assay variation was 5% while repeated assay of a reference plasma showed an intra-assay variation of 6%. To avoid possible intra-assay variations, all samples were assayed in a single RIA. The hypothalamus was dissected and GABA was assayed as described in Table 1 legend. Values represent the mean ± s.e.m. of at least five determinations.

*$P < 0.01$ versus saline-injected rats by Student's *t*-test.

Detection of GABA at AP level extends the list of neurotransmitters which have been identified in this glandular tissue[16]. In the absence of a synthetic pathway in the AP, the function of GABA-T at the AP level would be mainly to catabolise GABA released from CNS centres and then transported through the hypophysial portal circulation. The high GABA-T activity found in the AP could readily serve this function. However, in view of the maintenance of GABA titres, although low, in the ectopic gland, we cannot exclude the possibility that a fraction of the GABA measured in the AP gland *in situ* may derive from the systemic circulation.

Table 4 Effect of i.v.t. administration of EOS on the PRL rise induced by blockade of pituitary DA receptors with domperidone

	Plasma prolactin (ng ml^{-1})		
Treatment	Δt_{30}	Δt_{60}	Δt_{90}
Saline + DOM (8)	23.0 ± 5.6	25.8 ± 6.2	26.8 ± 5.7
EOS + DOM (7)	13.1 ± 3.4	13.6 ± 5.0	10.0 ± 2.3*

Sprague–Dawley male rats (200–220 g) were implanted via the lateral ventricle of the brain[32] and prepared with chronic indwelling jugular cannulae inserted into the right atrium[39]. After 2–3 days for recovery, they were given EOS (2 mg per kg in 10 μl saline) or saline injection and 3 h later received an i.v. injection of domperidone (DOM, Motilium, Janssen) 0.01 mg per kg, and were sampled from the jugular cannula for RIA determination of plasma PRL. Values refer to incremental changes (Δ) in plasma PRL (mean ± s.e.m.) recorded at various times after DOM administration (30, 60 and 90 min). Numbers of rats are indicated in parentheses. Baseline PRL levels were 7.8 ± 1.5 (mean ± s.e.m.) and 3.8 ± 0.7 ng ml^{-1} ($P < 0.05$) in saline + DOM and EOS + DOM-injected rats, respectively. Calculation of the areas subtended by PRL profiles revealed a significant difference between saline + DOM and EOS + DOM treated groups (181 ± 19 mean ± s.e.m. versus 122 ± 16, respectively, $P < 0.05$ by Student's *t*-test).

*$P < 0.05$ versus saline + DOM injected rats by Student's *t*-test.

The organisation of GABAergic pathways in the hypothalamus provides neuroanatomical evidence for an action of GABA exerted directly at the AP level. In addition to hypothalamic GABAergic fibres projecting to the MBH, there is evidence for the existence of a medial basal hypothalamic (tubero-infundibular) pathway which projects to the ME[25]. Experiments reported here involving i.v.t.-injected EOS suggest that the increase in GABA content at the AP level was the consequence of inhibition of GABA-T in this pathway with ensuing GABA loading in the stalk circulation. The time-related rise in AP GABA concentration after EOS strongly suggests this mechanism. GABA once released into the portal circulation would be competent to control in an inhibitory fashion PRL secretion from the AP, acting at the level of specific GABA receptor sites[10]. Since EOS, in contrast to muscimol[6], is unable to affect GABA receptor sites directly[17], the above is the more plausible explanation for the PRL-lowering effect of the centrally administered compound. Our data suggest that the inhibitory effect of GABA on plasma PRL occurs independently of DA changes.

The finding of GABA in the posterior lobe of the pituitary, and the increases in GABA titres after blockade of GABA-T confirm previous data[26] and may reflect a functional role for the amino acid at this level. A functional role for DA present in the neuro-intermediate lobe has been recently postulated[27].

The findings reported here underline the functional analogy between the anatomical and biochemical organisation of GABA and DA at ME–AP level, and suggest an important role for the amino acid in the control of PRL secretion.

Dopamine receptors in the retina may all be linked to adenylate cyclase

Keith J. Watling, John E. Dowling & Leslie L. Iversen

MRC Neurochemical Pharmacology Unit, Department of
Pharmacology, Medical School, Hills Road, Cambridge, UK

Dopamine seems to be the principal catecholamine in the vertebrate retina, where it is found in two types of neurone[1]. In most species, there is a subclass of amacrine cell which makes synapses on other amacrine cells in the inner plexiform layer[2]. In teleost fish and New World monkeys, the dopaminergic neurones are interplexiform cells which make synapses in both plexiform layers on horizontal, bipolar and amacrine cells[3]. In other dopamine-rich areas of the central nervous system, there is evidence for multiple dopamine receptor types[4–7], and two sub-types have been suggested[8]. D-1 receptors are associated with an adenylate cyclase system whereas D-2 receptors are not. D-2 receptors are characterised by a high affinity for the butyrophenones haloperidol[9] and spiperone[10], but these ligands also apparently bind to D-1 receptors[11]. The butyrophenone domperidone also binds to central dopamine receptors[12], but it is a very weak antagonist of dopamine-sensitive adenylate cyclase[13] (Table 1), suggesting that it may bind only to D-2 receptors. In the retina of many species, a dopamine-sensitive adenylate cyclase has been demonstrated[14,15], indicating the presence of D-1 receptors. We report here that there is no significant receptor-specific binding of ^{3}H-domperidone to retinal membranes, thus suggesting the absence of D-2 receptors in this tissue.

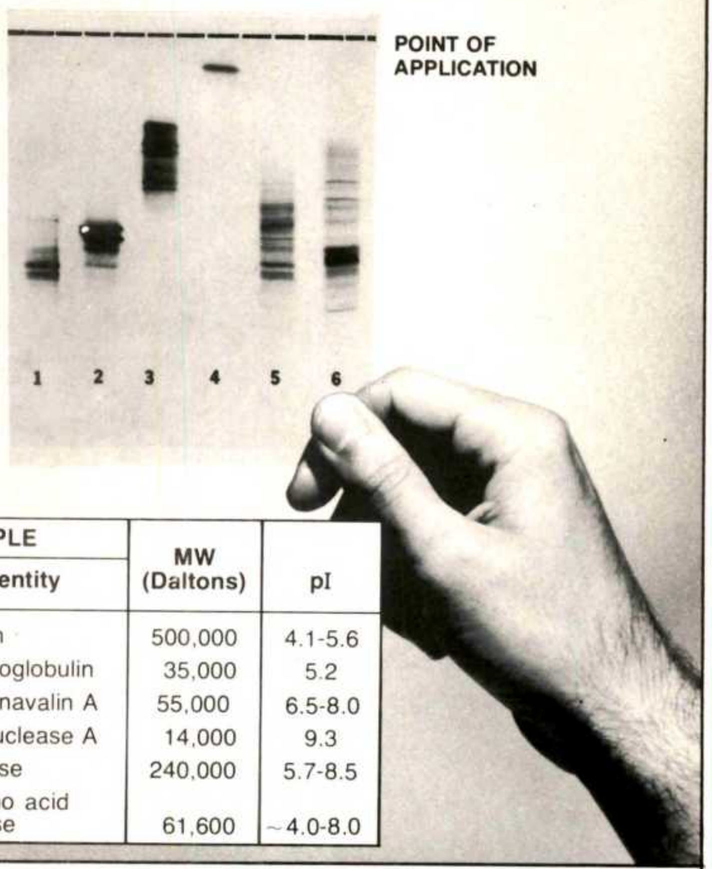
The dopamine-sensitive adenylate cyclase in the retina seems to be identical to that found elsewhere in the brain. Figure 1 shows, for example, adenylate cyclase activity in homogenates of the retina and corpus striatum of the guinea pig prepared in similar conditions. In both homogenates, dopamine elicits a dose-dependent stimulation of cyclic AMP formation, with maximal stimulation occurring at concentrations of 0.1–1 mM, and half-maximal stimulation with approximately 10μM dopamine. When expressed in terms of cyclic AMP produced above baseline levels, an average maximal response of 38.3 ± 6.7 pmol cyclic AMP per mg protein per min was obtained in four striatal homogenates, whereas a value of 47.3 ± 4.6 pmol per mg protein per min was obtained in seven retinal homogenates. These results indicate that there are substantial

Table 1 Inhibition of dopamine-stimulated adenylate cyclase in homogenates of guinea pig and carp retinae and rat striatum

	K_i values (M)		
Drug	Guinea pig retina	Carp retina	Rat striatum
Fluphenazine	3.9×10^{-9}	3.0×10^{-9}	4.3×10^{-9}
α-Flupenthixol	4.8×10^{-9}	5.1×10^{-9}	1.0×10^{-9}
(+)Butaclamol	2.4×10^{-8}	2.5×10^{-8}	8.8×10^{-9}
Chlorpromazine	4.5×10^{-8}	7.3×10^{-8}	4.8×10^{-8}
Haloperidol	9.0×10^{-8}	9.4×10^{-8}	9.1×10^{-8}
(−)Butaclamol	$>1\times10^{-6}$	$>1\times10^{-6}$	$>1\times10^{-6}$
Domperidone	$>1\times10^{-6}$	$>1\times10^{-6}$	$>1\times10^{-6}$

The effect of each drug on dopamine-stimulated adenylate cyclase activity in homogenates of carp and guinea pig retina was examined at six concentrations in the range 0.01–100 μM. Data are the results from two or three separate experiments involving quadruplicate determinations and s.e.m. values of < 10% of the mean. Drugs were added immediately before dopamine. K_i Values for each drug were calculated from the equation $IC_{50} = K_i(1 + S/K_m)$, where IC_{50} is the concentration of drug required to produce 50% inhibition of the maximum dopamine-induced response, S is the concentration of dopamine used (100 μM) and K_m is the concentration of dopamine producing half-maximal stimulation of adenylate cyclase (guinea pig, 10 μM: carp, 1 μM); $>1\times10^{-6}$ M = less than 50% inhibition at 100 μM. Competitive inhibition has been assumed for all compounds tested. K_i values for rat striatum are taken from previous reports (refs 5, 13, 16).

Marine Colloids' Unique IsoGel™ (Agarose) System opens up new frontiers in Isoelectric focusing.



SAMPLE No.	SAMPLE Identity	MW (Daltons)	pI
1	Ferritin	500,000	4.1-5.6
2	B-Lactoglobulin	35,000	5.2
3	Concanavalin A	55,000	6.5-8.0
4	Ribonuclease A	14,000	9.3
5	Catalase	240,000	5.7-8.5
6	L-amino acid oxidase	61,600	~4.0-8.0

- **Non Toxic and easy to use**
- **All proteins ($\leq 2 \times 10^6$) focused in less than 30 minutes**
- **Resolution as sharp as in Polyacrylamide**
- **Direct "fingerprinting" of untreated tissue**
- **Excellent reproducibility**
- **No photography or prolonged destaining required**
- **Dry, permanent record of each run within 30 minutes of the time you turn the power off**
- **The IsoGel system does away with the problems of Polyacrylamide and glass plates**

MORE THAN JUST A CELL...

BIO-RAD'S MODEL 1415 IS THE HEART OF AN ELECTROPHORESIS SYSTEM FOR ANALYTICAL AND PREPARATIVE ELECTROFOCUSING, IMMUNOELECTROPHORESIS AND DNA AGAROSE ELECTROPHORESIS!

125 x 430 mm cooling platform — gives tremendous flexibility

Condensation coil — eliminates buffer dripping on gels, fogging

Removable electrode/buffer chambers — easy emptying, easy cleaning

Direct contact electrofocusing electrodes — adjustable for running lengthwise or crosswise; dual electrode jacks for two simultaneous electrofocusing runs

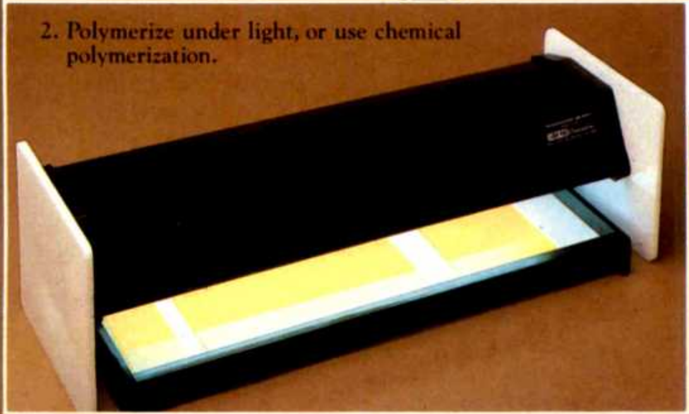
Complete systems — Four complete systems are available to take advantage of the versatility designed into the Model 1415 cell.

AND MORE THAN JUST ACCESSORIES...

The Analytical Electrofocusing system includes all of the Electrophoresis Purity reagents you need for high resolution electrofocusing plus a complete set of components—many of advanced design available nowhere else. It's one of four complete systems that can be used in combination with the Model 1415 and other horizontal cells. More than just accessories, these systems bring you new simplified techniques, greater economy and better results.

SIMPLIFY GEL CASTING

1. Lay plates on spacer rails and pipette monomer/ampholyte mixture under each plate.



2. Polymerize under light, or use chemical polymerization.

3. Lift completed gel plate from tray. Acrylic surface prevents sticking.

The versatile **Analytical Electrofocusing System, allows you to...**

cast thinner gels. Save ampholyte, improve resolution and improve heat dissipation over standard 2 mm thick gels with a choice of 1.6 or 0.8 mm thick gels.

cast and run three plate sizes. System includes 45 mm, 100 mm and 205 mm wide plates for running different numbers of samples. No need to cast gels larger than required.

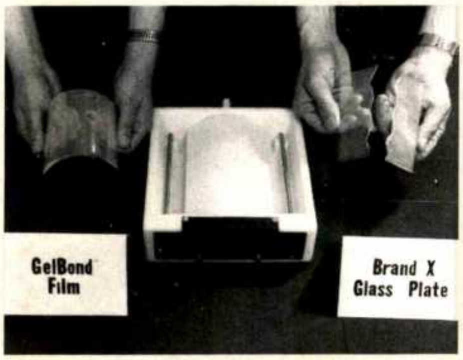
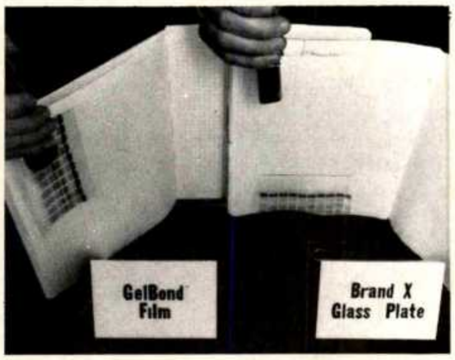
ELECTROPHORESIS?

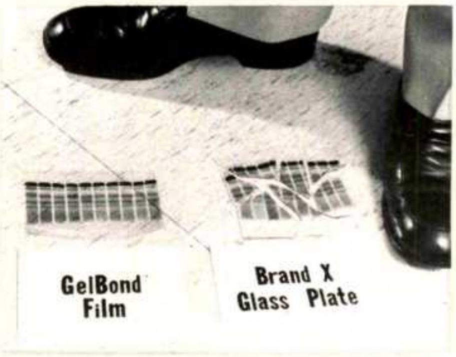
If you're still using glass plates, here are some facts MARINE COLLOIDS would like you to know



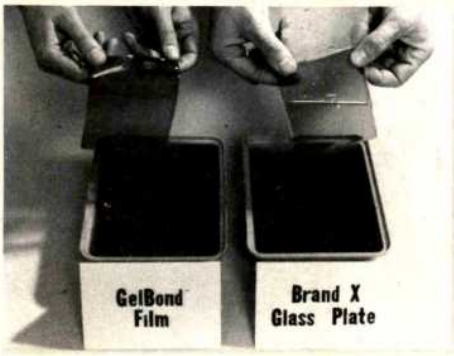
Flexible GelBond™ film
is easier to work with



GelBond becomes a permanent record,
easily stored, filed, projected



Glass is fragile; GelBond
won't break or splinter



Gels won't slide off GelBond
as with glass

Glass is 20X heavier
and bulkier than GelBond

GelBond costs less than half
as much as glass plates

One more advantage: If you recycle your glass plates, you can do away with that expensive photography to record results. With GelBond*, your results are already on film—GelBond film. So free your lab from the clutter of glass plates. Call or write for free samples of GelBond, the transparent, gel adhering polyester film. You'll find it clean, ready for use. It's the perfect gel support for agarose gel electrophoresis. Try it once. You'll never go back to the tyranny of glass plates. GelBond is available in sheets or rolls, in 4 or 7 mil thickness. In the U.S.A, call us toll-free at 1-800-341-1574. Or write FMC Corporation, Marine Colloids Division, Bio Products, Rockland, Maine 04841.

*GelBond is manufactured for Marine Colloids by the 3M C

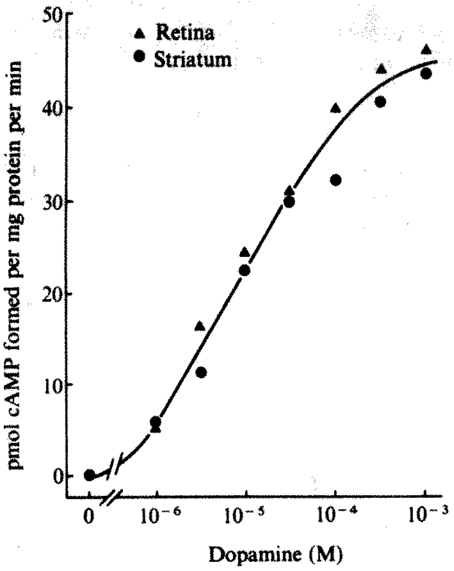

Fig. 1 Effect of dopamine on cyclic AMP production in homogenates of guines pig retina and striatum. Results are expressed as pmol cyclic AMP per mg protein per min produced above baseline levels. Each point is the mean of three separate experiments involving quadruplicate determinations. s.e.m. values were less than 20% of the mean. Adenylate cyclase activity was assayed using the method of Kebabian *et al.*[17] as follows. Retinae and striata were removed from guinea pigs (250–300 g) and separately homogenised in 2 mM Tris-maleate buffer containing 2 mM EGTA. Retinae were homogenised using a ratio of 1 retina to 500 μl buffer, and striata using a ratio of 1 mg wet weight striata to 25 μl buffer. Aliquots (20 μl) of this homogenate were added to assay tubes containing 130 μl of 80 mM Tris-maleate buffer (*p*H 7.4), 2 mM $MgSO_4$, 10 mM theophylline and 0.2 mM EGTA plus dopamine as indicated. The reaction in each tube was initiated by the addition of 50 μl ATP to a final concentration of 1 mM. The tubes were incubated with shaking at 30°C for 3 or 5 min and transferred to a boiling water bath for 3 min followed by centrifugation. Duplicate 10 μl samples of the final supernatant were assayed for cyclic AMP content by the method of Brown *et al.*[18]. Baseline cyclic AMP levels in four striatal homogenates were 70.6 ± 12.8 pmol cyclic AMP per mg protein per min and 19.4 ± 2.9 pmol cyclic AMP per mg protein per min in seven retinal homogenates. Protein contents were determined according to the method of Lowry *et al.*[19] using bovine serum albumin as a standard.

amounts of dopamine-sensitive adenylate cyclase, and presumably D-1 receptors, in both guinea pig retina and striatum.

Furthermore, in guinea pig retinal homogenates, neither the α-adrenoreceptor agonist phenylephrine nor the β-adrenoreceptor agonist isoprenaline produce any significant stimulation of adenylate cyclase at concentrations up to 100 μM, indicating that the catecholamine receptors linked to adenylate cyclase in the retina are specific for dopamine. In addition, various dopaminergic antagonists, including fluphenazine, α-flupenthixol, chlorpromazine and haloperidol, inhibit the retinal dopamine-sensitive adenylate cyclase with K_i values similar to those previously obtained in striatal homogenates[5] (Table 1). The dopamine-sensitive adenylate cyclase in retinal homogenates is also antagonised by the neuroleptic agent (+)-butaclamol, whereas (−)butaclamol is essentially inactive. This stereospecificity is also similar to that observed in striatal homogenates[5]. Finally, in agreement with results obtained in homogenates of rat striatum[13], domperidone shows no significant antagonism of the retinal dopamine-sensitive adenylate cyclase at concentrations up to 100 μM.

Significant binding of ^{3}H-domperidone can be demonstrated readily in guinea pig striatal homogenates (Fig. 2), and 85–90% of this binding is displaced by non-radioactive dopamine at a concentration of 1 mM, with 50% displacement of specific binding at 1 μM dopamine. These data indicate that there are many dopamine-specific binding sites for domperidone in the guinea pig striatum. In contrast, comparatively little ^{3}H-domperidone binding is detectable in similarly prepared homogenates of guinea pig retinae, and dopamine at concentrations up to 10 μM fails to displace any of the bound drug. A small amount of displacement seems to occur with dopamine concentrations of 100 μM and 1 μM, but this effect is not statistically significant.

The amount of non-displaceable ^{3}H-domperidone binding observed in retinal homogenates is comparable to the level of nonspecific binding remaining in striatal homogenates incubated with 1 mM dopamine, and probably represents binding of the ligand to non-receptor sites. In one homogenate of the rabbit retina there was a comparable small amount of ^{3}H-domperidone binding (2.5 fmol per mg wet weight tissue) which was also not affected by dopamine at concentrations up to 1 mM.

We have also studied the dopamine-sensitive adenylate cyclase and ^{3}H-domperidone binding in the carp retina, whose dopaminergic neurones are of the interplexiform type[3]. As in the guinea pig, a prominent dopamine-sensitive adenylate cyclase is present in this retina. This cyclase also seems to be identical to those in other retinae and other brain regions in terms of its specificity for dopamine, sensitivity to various neuroleptic drugs but insensitivity to domperidone (Table 1). As in the other retinae examined, no dopamine-displaceable ^{3}H-domperidone binding was observed in homogenates of the carp retina in five experiments. However, in carp, the amount of non-displaceable binding was approximately twice that found in the guinea pig (4.4 fmol, per mg wet weight compared with 2.8 fmol per mg wet weight).

In preliminary experiments, we have examined the binding of another butyrophenone derivative, ^{3}H-spiperone, to guinea pig and carp retinal homogenates. This ligand apparently binds to both D-1 and D-2 receptors in striatal homogenates[11]. In

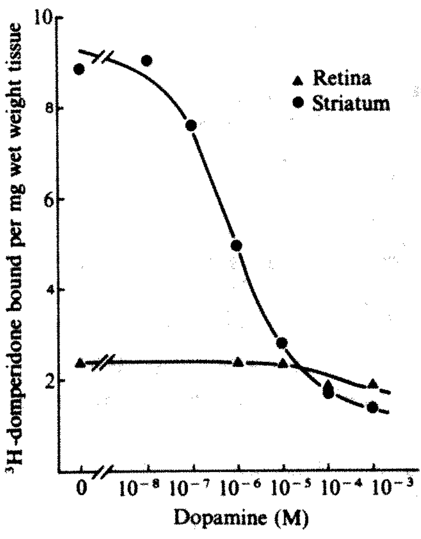

Fig. 2 Effect of dopamine on the binding of ^{3}H-domperidone to guinea pig striatal and retinal homogenates. Binding of ^{3}H-domperidone (corrected for filter blanks) to guinea pig striatal or retinal membranes, in the absence or presence of various concentrations of dopamine, is expressed as fmol bound per mg wet weight tissue. Each point represents the mean of four experiments involving triplicate determinations. s.e.m. values were less than 15% and 30% of the mean in the striatum and retina, respectively. Membrane preparations were prepared as previously described[10,20,21]. Incubation tubes containing 50 μl ^{3}H-domperidone (Janssen, specific activity 10 Ci $mmol^{-1}$) to give a final concentration of 1 nM, 50 μl dopamine (final concentration as indicated) or distilled water and 900 μl homogenate (equivalent to ~5 mg wet weight of original tissue for striatum and 7–10 mg wet weight of original tissue for retina) were incubated for 20 min at 30°C. Membranes were then collected by filtration, washed, and the bound radioactivity determined[10,20,21]. Total binding of ^{3}H-domperidone was 8.87 ± 0.16 and 2.38 ± 0.38 fmol per mg wet weight tissue in striatum and retina, respectively. In the presence of 1 mM dopamine, this binding was reduced to 1.38 ± 0.11 and 1.86 ± 0.39 fmol per mg mg wet weight tissue.

agreement with this, we have observed a significant amount of dopamine-displaceable ^{3}H-spiperone binding in both these retinae.

In conclusion, our results suggest that the retina may represent an area of the vertebrate central nervous system which contains a pure population of D-1 receptors; that is, all linked to adenylate cyclase. This situation apparently holds regardless of the type of dopaminergic neurone present in the retina. Thus, whether the dopaminergic neurones are a class of amacrine cell, as in the guinea pig or rabbit, or interplexiform cells, as in the carp, no D-2 dopamine receptors seem to be present. These results further imply that all neurones postsynaptic to the retinal dopaminergic cells, namely amacrine cells in the guinea pig and rabbit, and bipolar, horizontal and amacrine cells in the carp, possess a dopamine-sensitive adenylate cyclase.

We thank John Horne for carrying out several of the experiments on the guinea pig retinal adenylate cyclase and Dr P. Laduron (Janssen) for providing the ^{3}H-domperidone. Combined effects of adrenaline and insulin on active electrogenic Na^+–K^+ transport in rat soleus muscle

J. A. Flatman & T. Clausen

Institute of Physiology, University of Aarhus, 8000 Aarhus C, Denmark

Both β_2-adrenoreceptor stimulants (such as adrenaline and salbutamol) and insulin can increase active Na^+–K^+ transport[1–6] and hyperpolarise skeletal muscle cells[1,2,7–9]. Thus, adrenaline and insulin, which are otherwise antagonistic regulators of several metabolic processes, have one action in common, namely, stimulation of active ion translocation. This is especially interesting as cyclic AMP stimulates Na^+–K^+ transport[2], whereas a lowering of the cytoplasmic concentration of cyclic AMP has been proposed as an early signal in the action of insulin[10,11]. Here we report the results of experiments in which the active Na^+–K^+ transport and membrane potential (E_M) of rat soleus muscles were studied during the action of supramaximal doses of insulin and β_2-adrenoreceptor stimulants, alone and in combination. We conclude that the stimulant action of insulin on active electrogenic Na^+–K^+ transport is unlikely to be evoked by a lowering of the intracellular concentration of cyclic AMP.

All experiments were carried out using the rat soleus muscle. The techniques for measuring Na^+–K^+ transport and E_M have been described in detail previously[2,6,12]. For the measurements of the content and transport of Na^+ and K^+, muscles obtained from rats weighing 60–70 g were used. It was earlier demonstrated that there is no significant difference between the E_M of muscles from small (60–70 g) and large (200–400 g) rats[2]. As large fibres allow more stable recordings, the major part of the present measurements *in vitro* and *in vivo* were carried out using animals weighing 200–400 g.

In vivo recordings of E_M were made using pentobarbitone-anaesthetised rats weighing 300–400 g. In these experiments, the dorsal surface of the right soleus muscle was exposed at the bottom of a 'pool' formed by lifting the edges of the skin incision. The muscle surface was covered by a thin layer of standard Krebs–Ringer bicarbonate buffer on which a light paraffin oil was layered. The temperature of the pool and the body of the animal was maintained at 37 °C using a thermostated heating blanket. Venous blood samples were taken through a catheter in the left superior vena cava and drugs infused through a catheter in the left femoral vein. A Ag/AgCl reference electrode was buried in the left thigh muscles (the details of this technique are described elsewhere[13]).

Supramaximal concentrations of either adrenaline (10^{-5} M) or insulin (100 mU ml^{-1}) stimulated ^{22}Na efflux and ^{42}K influx (Table 1), and increased E_M within approximately the same interval of time (Table 2). These large doses were used to ensure that maximal stimulation was evoked by each agent alone. The effects of insulin were somewhat less pronounced and slower in onset than those of adrenaline. Ouabain (10^{-3} M) blocked the hyperpolarising effect of both hormones (Table 2), indicating that this is related to a stimulation of active Na^+–K^+ transport. The effects of adrenaline and insulin were partially additive on Na^+–K^+ transport, whether the insulin was added before, after or simultaneously with adrenaline (as in Table 1). On the other hand, although the addition of adrenaline to muscles already exposed to insulin gave a further hyperpolarisation, this was smaller than that produced by adrenaline alone. Moreover, the hyperpolarisation produced by adrenaline was significantly reduced by the later addition of insulin. Similar results were obtained with salbutamol alone or combined with insulin (Table 2).

Also *in vivo*, salbutamol and adrenaline produced a hyperpolarisation[13,14]. This was dose dependent and accompanied by a small reduction of plasma K^+. The hyperpolarisation produced by a supramaximal salbutamol concentration *in vivo* was larger than that evoked by a similar concentration *in vitro*. Insulin, whether released in response to the intravenous (i.v.) injection of glucose (Table 3) or injected i.v., also produced a hyperpolarisation and a non-significant fall of plasma [K^+]. The i.v. injection of 0.5 IU insulin to a 250-g rat produced a hyperpolarisation of 15.2 mV (from −69.9 ± 0.6 [39 observations] to −85.1 ± 0.5 [44]) which was seen in all four fibre layers investigated. The much larger response to exogenous insulin is poss-

Table 1 Effect of insulin and adrenaline on ^{22}Na washout and ^{42}K uptake in rat soleus muscle

	^{22}Na Efflux (min^{-1})	*P*	^{42}K Influx (μmol per g per min)	*P*
Control	0.058 ± 0.002 (5)		0.54 ± 0.02 (8)	
		<0.001		<0.005
Insulin (100 mU ml^{-1})	0.081 ± 0.004 (6)		0.65 ± 0.03 (8)	
		<0.005		<0.001
Insulin (100 mU ml^{-1}) + adrenaline (10^{-5} M)	0.103 ± 0.004 (6)		0.81 ± 0.02 (8)	
		>0.10		<0.01
Adrenaline (10^{-5} M)	0.098 ± 0.004 (6)		0.71 ± 0.02 (8)	

For experimental details, see refs 2 and 6. The rate of ^{22}Na washout is given as the fraction of ^{22}Na activity lost from the tissue per min, and ^{42}K uptake as the amount of ^{42}K activity gaining access to the tissue compartment not available to ^{14}C-sucrose. The measurements were carried out within the first 10 min of exposure to the hormones, and all results are given ±s.e.m. with the number of observations in parentheses.

Table 2 The action of insulin and adrenaline on the E_M of rat soleus muscle

Muscle	Additions	ΔE_M(mV)	*n*	*P*
(i)				
a	Insulin	+3.5±0.2	(199/5)	<0.001
	Insulin + adrenaline	+7.3±0.3	(192/5)	
b	Adrenaline	+7.4±0.4	(194/5)	<0.001
	Adrenaline + insulin	+6.0±0.3	(182/5)	
a	Insulin	+3.6±0.4	(151/4)	<0.001
	Insulin + salbutamol	+9.3±0.4	(146/4)	
b	Salbutamol	+9.1±0.4	(144/4)	<0.10
	Salbutamol + insulin	+8.1±0.4	(155/4)	
(ii)				
a	Insulin	+4.3±0.4	(171/4)	<0.001
b	Ouabain + insulin	−0.5±0.4	(172/4)	
a	Adrenaline	+5.8±0.7	(115/5)	<0.001
b	Ouabain + adrenaline	−0.9±1.0	(136/5)	

(i) The action of insulin (100 mU ml^{-1}) and adrenaline (10^{-5} M), or insulin (100 mU ml^{-1}) and salbutamol (10^{-5} M), applied individually or in combination, on the E_M of rat soleus muscle fibres (animal size 200–400 g). Paired experiments were carried out in which insulin was added either before (muscles *a*) or after (muscles *b*) the β_2-adrenoreceptor agonist (using contralateral muscles of the same rats). A series of penetrations was first made while the muscle was bathed in drug-free Krebs–Ringer bicarbonate buffer (control). A further series of penetrations was started when the maximum drug-induced hyperpolarisation had been reached, that is, about 7 min after the bath concentration of β_2-adrenoreceptor agonist was brought to 10^{-5} M (ref. 2). In the experiments with insulin, the maximum rise was only reached 15 min after the onset of exposure. Although the ion contents of the muscle as a whole continued to change after these time intervals, no further change of potential was noted. The mean (±s.e.m.) changes in E_M produced by drug addition, compared with the drug-free control E_M, are tabulated (ΔE_M). *n* Indicates the number of fibres penetrated and the number of muscles investigated.

(ii) The action of insulin (100 mU ml^{-1}) and adrenaline (6×10^{-6} M) on the E_M of rat soleus muscle fibres in the absence and presence of ouabain (10^{-3} M). Paired experiments were carried out in which insulin was added to the soleus muscles of 250-g rats individually, or after the muscles had been pretreated with ouabain (contralateral muscles). This lasted 30 min to allow time for ouabain-induced muscle fibrillations to cease. In a corresponding series carried out on 60-g rats adrenaline was added alone or after ouabain pretreatment. The penetrations were timed as in (i). The *P* values given express the significance of difference between ΔE_M values obtained with one agent alone or two agents combined. Except in the presence of ouabain, all test values were significantly different ($P < 0.001$) from the control values obtained in drug-free solution.

Table 3 Effect of i.v. administration of glucose on serum K$^+$, serum insulin and E_M of rat soleus muscle *in vivo*

	Control ±s.e.m.	10–20 min after glucose i.v. ±s.e.m.	Δ	*n*	*P*
Serum [K$^+$] (mM)	4.2±0.2	3.9±0.1	−0.3	8/4	>0.10
Serum insulin (μM ml^{-1})	20±3	179±16	+159	4/2	<0.001
E_M (mV)	−70.3±0.6	−75.8±0.6	+5.5	130/4	<0.001

Female fed rats weighing 300–400 g were anaesthetised with pentobarbitone and the dorsal surface of the right soleus muscle exposed to allow the recording of E_M. Following a control period, each animal was given an i.v. injection of D-glucose (1 mg per g body weight) and the changes in serum K$^+$, serum immunoreactive insulin and E_M were recorded. Control experiments in which mannitol (1 mg per body weight) was given instead of glucose showed no significant change in any of these parameters. *n* Indicates the number of observations and the number of animals.

Table 4 Effect of adrenaline and insulin on Na$^+$–K$^+$ contents in isolated rat soleus muscle

	Na$^+$ Content (μmol per g wet weight)		K$^+$ Content (μmol per g wet weight)	
Control	10.9±0.4 (7)		77.5±1.2 (7)	
		$P < 0.001$		$P < 0.001$
Adrenaline (10^{-5} M)	5.9±0.5 (6)		84.1±0.8 (6)	
		$P < 0.01$		$P < 0.001$
Adrenaline (10^{-5} M) + insulin (100 mU ml^{-1})	3.7±0.4 (6)		94.1±1.6 (6)	
		$P < 0.001$		$P < 0.005$
Insulin (100 mU ml^{-1})	8.5±0.5 (7)		85.1±1.7 (7)	

Groups of six or seven muscles were incubated for 90 min in 3 ml of Krebs–Ringer bicarbonate buffer containing 1 mM ^{14}C-sucrose with or without the additions indicated. They were then blotted, homogenised in 4 ml 5% trichloroacetic acid and the extract centrifuged. Aliquots of the clear supernatant were taken for flame photometry and measurement of ^{14}C activity. The Na$^+$–K$^+$ contents of the tissue compartments not available to ^{14}C-sucrose were calculated and expressed as μmol per g tissue wet weight. The results are given as mean ±s.e.m. with the number of observations in parentheses.

ibly related to the hypoglycaemia and the ensuing catecholamine release from the adrenals. *In vivo*, the combined action of adrenoreceptor agonists and insulin was additive. In two animals (250 g) the injection of 50 μg salbutamol produced a hyperpolarisation of 12.2 mV (from −66.2±0.6 [40 observations/2 muscles] to −78.4±0.5 [52/2]). The subsequent injection of 1 IU of insulin produced a further 4.6 mV hyperpolarisation (to −83.0±0.5 [64/2]).

As demonstrated earlier, stimulation of the active Na$^+$–K$^+$ transport, whether induced by insulin[6] or adrenaline[2], leads to a drop in the intracellular Na$^+$–K$^+$ concentration ratio (Table 4). Again, the actions of the two hormones on Na$^+$–K$^+$ distribution seems to be additive, indicating that even during a long-term exposure, their respective sets of cellular signals do not interfere with each other.

There is strong evidence that among the cellular signals initiated by adrenaline, cyclic AMP is important in eliciting a variety of effects produced by β_2-adrenoreceptor stimulation. Both cyclic AMP and dibutyryl cyclic AMP (in combination with the phosphodiesterase inhibitor, theophylline) stimulate the active electrogenic Na$^+$–K$^+$ transport[2]. Our observations are not readily compatible with the assumption that the action of insulin on Na$^+$–K$^+$ transport (judged by the measurement of active ion fluxes and cell Na$^+$–K$^+$ content) is secondary to a decrease in the concentration of cytoplasmic cyclic AMP. It seems reasonable to conclude that the system mediating active Na$^+$–K$^+$ transport is sensitive to two hormonal regulators sharing a final common path (see ref. 15).

The finding that a combination of β_2-adrenoreceptor agonist plus insulin can produce a hyperpolarisation that is significantly smaller than that of β_2-adrenoreceptor agonist alone does not correlate with the studies of ion transport and contents. This discrepancy may be explained if insulin not only induces a stimulation of a 3:2 coupled active Na$^+$–K$^+$ transport[6] but also increases the membrane permeability to Na$^+$ (ref. 8). A permeability increase could thus 'shunt' electrogenic ion translocation, or directly depolarise the membrane. However, we cannot explain why a change in the sequence of addition of insulin and adrenaline can produce significantly different results.

We thank M. Stürup-Johansen for technical assistance. This investigation was supported in part by a grant from Århus Universitets Forskningsfond.

Contractions of cat small intestinal smooth muscle in calcium-free solution

Allen W. Mangel, D. O. Nelson, John A. Connor & C. Ladd Prosser

Department of Physiology and Biophysics, University of Illinois, Urbana, Illinois 61801

A rise in internal Ca^{2+} is the signal which activates the contractile mechanism in muscle. In striated muscle there is a well developed sarcoplasmic reticulum which stores and releases the bulk of the Ca^{2+} involved in the contraction cycle[1,2], allowing the muscle to operate relatively independently of external calcium levels. In smooth muscle the sarcoplasmic reticulum system is much less extensive[3,4] and normal contractile activity is very sensitive to calcium levels in the bathing medium[5–7]. These findings, together with the small size of smooth muscle cells which minimises diffusion time from the plasma membrane to the contractile apparatus, have suggested to some investigators that the Ca^{2+} which enters the cell during Ca^{2+}-mediated action potentials is either sufficient by itself to activate contraction or is a necessary trigger for the further release of Ca^{2+} from internal stores[8–11]. This notion is given support by the observation that contractile activity rapidly dies out when smooth muscle preparations are exposed to calcium-free solutions. However, electrical activity is eventually lost in these solutions. We report here on spontaneous contractile and electrical activity, and evoked mechanical activity, recorded after prolonged exposure to calcium-free EGTA saline in intestinal smooth muscle of cat.

Segments of small intestine were removed from cats anaesthetised with α-chloralose and placed immediately into Krebs solution of the following composition (mM): NaCl, 118.5; KCl, 4.7; $MgCl_2$, 1.2; $NaHCO_3$, 23.8; KH_2PO_4, 1.2; $CaCl_2$, 2.5, and glucose 5.5 (ref. 12). External electrical recording techniques were used[11]. Mechanical recordings were made with an isometric tension transducer (Grass Instruments model FTO3C). Experiments were performed at 35–37 °C.

Normal electrical activity in cat small intestine consists of slow rhythmic depolarisations (slow waves) with spike potentials often superimposed near the slow wave peak. The slow depolarisation is maintained for 2 to 4 s and peak amplitude recorded intracellularly ranges between 16 and 40 mV in normal musculature[12]. Spike potentials seldom reach 0 mV in intracellular recordings. When gross contractions occur they are associated with spike activity.

Prosser *et al.*[13] showed that normal electrical activity in cat small intestine was eliminated by incubation in Krebs solution containing no added calcium and 5–10 mM EGTA ('calcium-free Krebs'). Following periods of electrical quiescence which ranged from 10 to 40 min, the muscle developed prolonged potentials in the calcium-free Krebs solution. Intracellularly recorded, the potentials were approximately 40 mV in amplitude. Thus the prolonged potentials apparently result from sodium ions traversing channels normally used by calcium.

Mechanical and electrical events in control Krebs, during the period immediately after exposure to calcium-free Krebs and after incubation for 40 min in calcium-free Krebs, are shown in Fig. 1*a*, *b*, *c*. The prolonged potentials developed in approximately 40% of the preparations tested, and rhythmic contractions, such as those shown in Fig. 1*c* and 1*d*, were displayed by 90% of these spontaneous preparations. The mean amplitude of the EGTA contractions was 65% of the control contractions, although some were larger than control activity. Calcium-free Krebs flowed continuously through the chamber during experiments.

To exclude the possibility that calcium might be leached from the mucosa into the interstitial fluid and act as an extracellular calcium store to the muscle cell, 30 preparations in which the mucosa was surgically removed were tested. The results of incubation of mucosa-free preparations in calcium-free saline were qualitatively the same as those obtained for intact preparations except the success rate of obtaining EGTA-induced activity was diminished in preparations devoid of the mucosa, possibly due to the more extensive manipulation of the tissue.

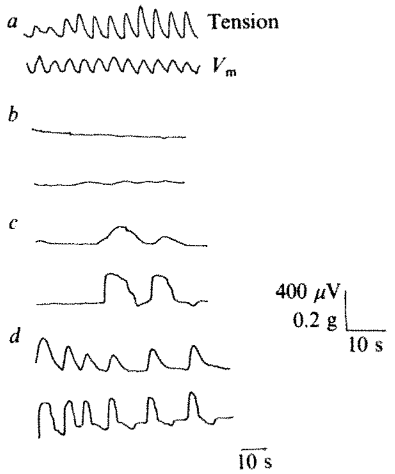

Fig. 1 *a*, Pressure electrode[11] recording of electrical activity (V_m, lower trace) and corresponding mechanical activity (upper trace) in control saline solution. *b*, Resulting activity following incubation for 7 min in calcium-free saline. *c*, Exposure for 40 min to calcium-free saline. *d*, Approximately 47 min exposure to calcium-free solution. Note change in time calibration.

Electrical stimulation could induce contractions in preparations remaining quiescent in calcium-free solution (Fig. 2). In some cases these preparations developed spontaneous electrical and contractile activity after stimulation. In other quiescent preparations barium chloride was applied and induced spikes with accompanying contractions (Fig. 3). Either treatment was effective even after preparations had been in calcium-free saline for over 2 h.

In the barium experiments the possibility exists of direct activation of the contractile apparatus by barium. However, this seems unlikely in view of the relative concentrations involved. Ebashi *et al.*[14] demonstrated that myosin B preparations from chicken gizzard and bovine aortic muscles are approximately 200 times less sensitive to barium than to calcium. Barium-induced contractions in calcium-free saline can be as large as control contractions, suggesting that internal barium levels would have to approximate 200 times internal calcium levels during peak contractions (~2 μM level for calcium-activated contractions). We would suggest, instead, that barium acts by supporting large action potentials[15] and that the plasma membrane depolarisation results in a release of internal calcium. The action of barium would then be similar to direct electrical stimulation on preparations in calcium-free saline.

Barrett and Barrett[16] have demonstrated the existence of a 'protected' extracellular compartment of calcium in frog skeletal muscle. The contents of this compartment were not removed by incubation of muscles in solutions with no added calcium plus 1 mM EGTA but were removed by high EGTA saline. To eliminate the possible presence of a 'protected' extracellular calcium compartment in cat small intestine, we incubated

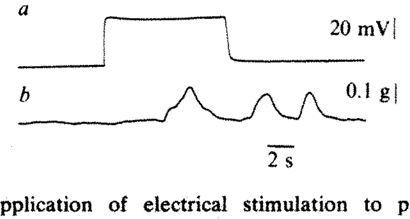

Fig. 2 Application of electrical stimulation to preparation remaining quiescent after exposure for 30 min to calcium-free saline. Preparation is mucosa free.

0028–0836/79/420582—02$01.00

mucosa-free preparations in 10 mM EGTA for 20 min and then in 30–50 mM EGTA for 30 min. Contractions could be elicited by electrical stimulation or barium chloride for the first 10 min in high EGTA. The final muscle contraction in high EGTA did not relax and tension thereafter showed a slow, steady increase, indicating that the muscle may have gone into contracture. This state was observed for periods of up to 20 min but may have lasted significantly longer. High EGTA concentrations might have induced contracture by large membrane depolarisations[16].

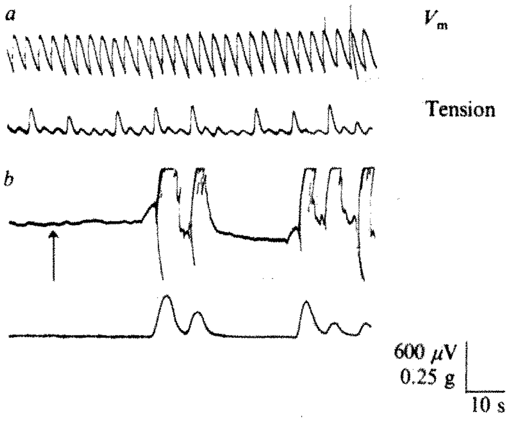

Fig. 3 *a*, Volume recording of electrical activity (upper trace) and corresponding mechanical activity (lower trace) in control saline solution from a mucosa-free preparation. *b*, Thirty seconds (at arrow) after the start of 3 mM $BaCl_2$ in calcium-free saline; the preparation was incubated in calcium-free saline for 175 min.

Our findings are similar to those of Somlyo *et al.*[4] who observed spontaneous contractions of turtle oviduct that persisted for ~30 min in calcium-free saline (4 mM EGTA). These investigators concluded that intracellular as well as extracellular sources of calcium can contribute to activation of contraction in smooth muscle. In contrast, others have reported that rhythmic mechanical activity is eliminated by EGTA[17,18]. It is possible that these observations were made during a time corresponding to the transition period between normal activity and EGTA-induced activity in our experiments.

In the calcium-free solutions it is unlikely that there is an appreciable inward-directed calcium gradient. The ability of prolonged potentials, barium spikes or electrical stimulation to induce contractile activity then suggests that an influx of calcium is not a prerequisite for contractions to occur and that internal stores of calcium which may be released by membrane depolarisation can support the contractile process. It is not clear to what extent this internal store of calcium participates in contractions in physiological conditions. Since the contractions we observed in calcium-free saline lasted for up to 1 h, it seems probable that a substantial portion of the activating calcium is recycled and therefore not readily accessible to extrusion mechanisms such as Na–Ca exchange.

Control of cytoplasmic actin gel–sol transformation by gelsolin, a calcium-dependent regulatory protein

Helen L. Yin & Thomas P. Stossel

Hematology-Oncology Unit, Massachusetts General Hospital,
Department of Medicine, Harvard Medical School, Boston,
Massachusetts 02114

The peripheral cytoplasm of macrophages is involved in the control of locomotion, secretion and endocytosis, events common to many eukaryotic cells. During these activities, the cortical cytoplasm, which contains numerous actin filaments[1,2], appears to undergo reversible gel–sol transformations[3]: cycles of gelation and solation are demonstrable in suitably prepared macrophage extracts, and the gels contain tangled actin filaments[4]. These changes in consistency of cytoplasmic actin may regulate motile events in the macrophage periphery. Calcium in micromolar concentrations prevents gelation of crude macrophage cytoplasmic extracts[4], providing a possible link to abundant indirect evidence implicating calcium in the regulation of locomotion, secretion and endocytosis[5]. Similar calcium-sensitive gelation phenomena occur in crude cell extracts from diverse cell types and may have a relevance for control of cell movements in general[6–11]. Actin gelation results from the cross-linking of actin filaments (F-actin) by other proteins. In macrophages, a high molecular weight actin-binding protein (ABP) is the principal actin cross-linking protein[12]. Cross-linking of actin by these purified actin-binding proteins, however, is insensitive to changes in the calcium concentration[4,12], so that another factor must mediate the expression of a calcium effect. We have now isolated such a calcium-dependent regulatory protein from macrophages and call it gelsolin.

Rabbit lung macrophage cytoplasmic extracts, prepared in buffered sucrose solution containing protease inhibitors[12] and 5 mM EGTA, solidified to form gels when warmed in the presence of 0.1 M KCl. Addition of calcium chloride to micromolar-free calcium concentration inhibited gelation and caused solation of existing gels. Chelation of Ca^{2+} with EGTA restored gelation to the calcium-treated extract, ruling out calcium-dependent denaturation of the gelation components. The fluid expressed from gelled extract by centrifugation at 12,000*g* for 15 min at 25 °C, designated S2, did not gel by itself. However, it inhibited the gelation of rabbit muscle F-actin by purified macrophage ABP or chicken gizzard filamin in the presence of Ca^{2+}. Excess EGTA restored gelation. The experimental conditions used to demonstrate the Ca^{2+}-dependent regulator activity in S2 were as described in Table 1 for the purified gelsolin protein, and the results were qualitatively similar. The inhibitory activity in S2 was sensitive to trypsin digestion (1 mg ml^{-1} for 30 min at 25 °C) and boiling at 100 °C for 1 min.

The regulatory activity in S2 was purified by sequential ion-exchange chromatography and gel filtration (Fig. 1). The gelation inhibitory activity eluted from a DEAE-Sepharose column in one symmetrical peak at KCl concentrations between 0.10 and 0.15 M, and eluted in a single symmetrical peak from a Sephadex G-200 column. Based on the elution of globular proteins with known molecular weights from this column, the regulator protein had an apparent molecular weight (MW) of 160,000. The purification recovered 26–69% of the gelation inhibitory activity present in S2 and enriched the specific inhibitory activity 36- to 61-fold. Purification of the calcium-dependent inhibitory activity coincided with the enrichment of a

0028-0836/79/420583—04$01.00

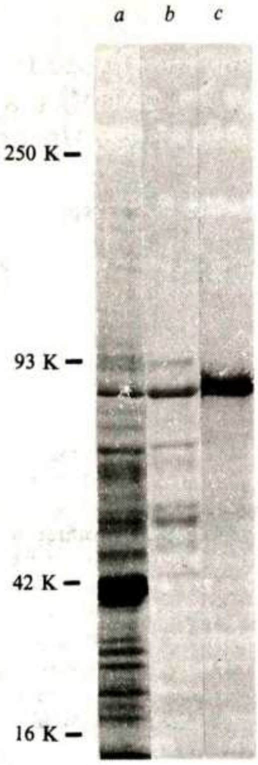

Fig. 1 Purification of gelsolin. All purification procedures were carried out in the cold. S2 (100 ml) was dialysed against 30 volumes of a solution containing 1 mM EGTA, 1 mM dithiothreitol, 0.5 mM ATP and 9 mM imidazole-HCl, *p*H 7.8. The dialysed sample was applied to a DEAE-Sepharose column (1.5 × 21 cm) equilibrated with the same buffer. The adherent proteins were eluted with a 500 ml linear 0–0.6 KCl concentration gradient. Fractions with gelation inhibitory activity (determined as described below) were pooled and solid ammonium sulphate was added to a final concentration of 306 mg ml^{-1}. The precipitated proteins were collected by centrifugation at 15,000*g* for 10 min, dissolved in 1 ml of a solution containing 0.8 M KCl, 1 mM EGTA, 5 mM dithiothreitol, and 10 mM imidazole-HCl, *p*H 7.5, and dialysed against the same solution. This solution was used for equilibration and elution of a Sephadex G-200 column (1.6 × 90 cm) to which the sample was applied. Calcium-dependent inhibition of actin gelation by the eluted fractions was measured by the sedimentation assay of Brotschi *et al.*[12]. Rabbit muscle F-actin (2 mg ml^{-1} prepared as in ref. 14, and filamin (0.05 mg ml^{-1}, prepared as in ref. 13) were incubated with the fractions to be tested in a solution of 0.1 M KCl, 20 mM imidazole-HCl, *p*H 7.2, 0.045 mM $CaCl_2$, for 30 min at 25 °C. Samples were centrifuged at 10,000*g* for 10 min at 20 °C and protein concentrations of the supernatant were determined by the method of Lowry[15]. The difference in protein concentrations between the initial reaction mixture and the final supernatant was a measure of the amount of protein incorporated into the sedimented gel pellet. The concentration of cross-linker in the control sample (without inhibitor) was adjusted to sediment about 50% of the total actin by 10 min, and the sedimentation rate was constant with time over this period. A decrease in actin plus cross-linker sedimented in the presence of added test fractions indicated an inhibition of gelation. The specific inhibitor activity was computed as: (mg protein sedimented in control − mg protein sedimented in sample with test protein)/mg test protein. Proteins from each purification step containing inhibitory activity were boiled for 1 min in 8 M urea, 10% SDS, 2% 2-mercaptoethanol and resolved by electrophoresis in 5–15% polyacrylamide gradient slab gels in the presence of SDS[16]. *a*, Macrophage S2 extract, 300 μg; *b*, DEAE-Sepharose fraction, 300 μg; *c*, Sephadex G-200 fraction, 50 μg. The subunit MWs (×10^{-3}) of standard proteins are indicated.

Table 1 Calcium-dependent reversible inhibition of actin gelation by gelsolin

	Treatment		
Proteins	First incubation	Second incubation	Gelation %
1. Actin, ABP	Ca^{2+}	—	100
2. Actin, ABP	EGTA	—	100
3. Actin, ABP, gelsolin	Ca^{2+}	—	0
4. Actin, ABP, gelsolin	EGTA	—	91
5. Actin, gelsolin	Ca^{2+}	—	0
6. Actin, gelsolin	EGTA	—	0
7. Actin, ABP, gelsolin	Ca^{2+}	EGTA	76
8. Actin, ABP, gelsolin	EGTA	Ca^{2+}	33
9. Actin, filamin	Ca^{2+}	—	100
10. Actin, filamin	EGTA	—	112
11. Actin, filamin, gelsolin	Ca^{2+}	—	0
12. Actin, filamin, gelsolin	EGTA	—	99
13. Actin, filamin, gelsolin	EGTA	Ca^{2+}	25

F-actin (2 mg ml^{-1}), actin cross-linking proteins (macrophage ABP, 0.024 mg ml^{-1} prepared as in ref. 12, or chicken gizzard filamin, 0.045 mg ml^{-1}) and gelsolin (0.025 mg ml^{-1}) were incubated in a solution containing 0.1 M KCl, 20 mM imidazole-HCl, *p*H 7.2, either 0.07 mM $CaCl_2$ or 1 mM EGTA, for 30 min at 25 °C. Samples no. 8 and 13 contained 0.2 mM EGTA. In a second incubation (40 min), EGTA was added to sample 7 to a final concentration of 1 mM, and $CaCl_2$ was added to samples 8 and 13 to 0.5 mM. An equivalent volume of buffer was added to the remaining tubes. Actin cross-linking was quantitated by the sedimentation assay of Brotschi *et al.*[12]. Data were pooled from three separate experiments, and gelation was expressed as per cent of that observed in paired control samples (without gelsolin). 100% gelation for the experiment shown in lines 1–6 was 0.7 mg ml^{-1} after a 10 min centrifugation, 1.1 mg ml^{-1} for line 8 and 0.9 mg ml^{-1} for lines 9–13.

91,000-MW polypeptide resolved by SDS polyacrylamide gel electrophoresis. This polypeptide was the major Coomassie blue-stained protein of the pooled G-200 activity peak (Fig. 1*c*). We therefore concluded that the 91,000 polypeptides are subunits of gelsolin and, based on the gel filtration data, suggest that the native molecule contains two of these subunits. Purified gelsolin, like the inhibitory factor in S2, was heat-labile, and conferred reversible calcium sensitivity to the gelation of actin filaments by actin cross-linking proteins (Table 1). Gelation of rabbit muscle actin by purified rabbit macrophage ABP was insensitive to Ca^{2+} (lines 1 and 2). Actin gelation by macrophage ABP became sensitive to Ca^{2+} when gelsolin was included: gelation was inhibited completely in the presence of calcium (line 3) but not in the presence of excess EGTA (line 4). Gelsolin by itself did not cross-link actin (lines 5 and 6). The inhibitory effect of gelsolin was partially reversible; gelation was largely restored to a calcium-treated sample by subsequent addition of sufficient quantities of EGTA (line 8). Similar calcium-dependent inhibition of gelation occurred when filamin was used as the actin cross-linking agent (lines 9–13). Inhibition of gelation

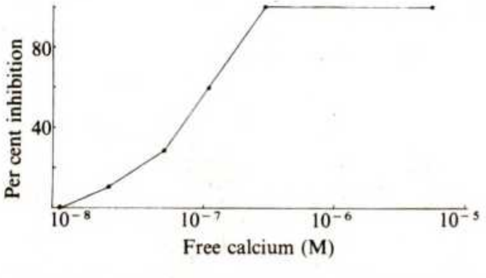

Fig. 2 Effect of calcium concentration on the inhibition of actin gelation by gelsolin. Gelsolin (0.03 mg ml^{-1}) was incubated with F-actin (2.0 mg ml^{-1}) and filamin (0.07 mg ml^{-1}) in a solution containing 0.1 M KCl, 20 mM imidazole-HCl, *p*H 7.2. The free Ca^{2+} concentration was varied by the use of Ca/EGTA buffers containing 0.4 mM EGTA, and calculated with the computer program of Perrin and Sayce[17], as described by Potter and Gergley[18].

Table 2 Effects of gelsolin on filamin–actin binding and actin sedimentability

Proteins	Conditions	Per cent of each protein sedimented Actin	 Filamin	 Gelsolin	Weight ratios of sedimented proteins Filamin : actin	 Gelsolin : actin
1. Actin, filamin	Ca^{2+}	92	100	—	1:18	—
2. Actin, filamin, gelsolin	Ca^{2+}	82	100	47	1:16	1:55
3. Actin	Ca^{2+}	85	—	—	—	—
4. Actin, gelsolin	Ca^{2+}	71	—	47	—	1:48
5. Actin, filamin	EGTA	95	100	—	1:18	—
6. Actin, filamin, gelsolin	EGTA	93	100	18	1:18	1:163
7. Actin	EGTA	91	—	—	—	—
8. Actin, gelsolin	EGTA	91	—	15	—	1:192

F-actin (1.9 mg ml^{-1}) was incubated for 30 min at 25 °C with gelsolin (0.06 mg ml^{-1}) and filamin (0.1 mg ml^{-1}) in a solution of 0.1 M KCl, 20 mM imidazole-HCl, *p*H 7.2. Either 0.07 mM $CaCl_2$ or 0.4 mM EGTA was present. The tubes were centrifuged at 93,000*g* for 1.5 h at 4 °C. Equivalent aliquots of the initial mixtures and pelleted proteins were analysed by polyacrylamide gel electrophoresis in the presence of SDS[16]. The intensities of the Coomassie blue-stained bands were determined by scanning with a densitometer (E–Z Apparatus Corp), and the amounts of each protein sedimented were expressed as a percentage of that present in the initial mixtures.

occurred instantaneously, and the extent of inhibition was proportional to gelsolin concentrations. Assuming a MW of 90,000 for gelsolin subunit, the molar ratio of gelsolin subunit to actin monomers (MW 42,000) was 1:166, and gelsolin subunit to ABP or filamin (MW 500,000) was 1:0.45 when gelation was maximally inhibited.

Figure 2 shows the concentration of Ca^{2+} required for inhibition of actin gelation by gelsolin. These concentrations of free Ca^{2+} also inhibit gelation of cytoplasmic extract of macrophages and are within the limits observed in living cells.

To determine the site of action of gelsolin, we examined its effects on the binding of cross-linker proteins to actin, and on actin sedimentability and viscosity in the absence of cross-linking proteins. The binding of filamin and F-actin was determined from the extent of co-sedimentation of the two proteins at high centrifugal force. Filamin alone did not sediment. The amount of filamin which co-sedimented with F-actin was not changed after incubation with Ca^{2+} at a concentration of gelsolin in excess of that required to produce maximal inhibition of gelation (Table 2, lines 1, 2). In fact, because the sedimentability of actin decreased in the presence of gelsolin (compare lines 1 and 2), the filamin to actin weight ratios in the pellet increased slightly in the gelsolin-containing sample, compared with the control. Therefore, inhibition of gelation did not result from a decrease in the number of cross-linker molecules bound to the actin filaments.

A small decrease in actin sedimentability was also observed when actin was incubated with gelsolin and calcium in the absence of filamin (compare Table 2, lines 3 and 4). No change occurred in the presence of EGTA (compare lines 5 and 6, 7 and 8). A direct calcium-dependent effect of gelsolin on actin was demonstrable by measuring the viscosities of F-actin solutions. When an F-actin solution (2.0 mg ml^{-1}) was incubated with gelsolin (0.03 mg ml^{-1}), a concentration which completely inhibited gelation of actin by filamin, the specific viscosity, measured with Cannon–Manning microviscometers (size 100), decreased by 30% in the presence of Ca^{2+}, but did not change in the presence of EGTA. The Ca^{2+}-dependent drop in specific viscosity was equivalent to a decrease in F-actin concentration from 2.0 mg ml^{-1} to 1.3 mg ml^{-1}.

Although the decreases in actin viscosity and sedimentability are consistent with shortening of actin filaments, it is clear from the small magnitude of the change that a substantial amount of gelsolin-treated actin remained in the polymerised state in conditions of complete inhibition of actin gelation.

Gelsolin may exert its effects by binding to actin in the presence of calcium. Gelsolin alone did not sediment under high-speed centrifugation. After incubation with F-actin and Ca^{2+}, about half of the added gelsolin co-sedimented with actin (Table 2, line 4). Addition of filamin did not change the proportion of gelsolin co-sedimented with actin (line 2), suggesting that gelsolin bound directly to actin and not filamin. In these experiments, a large amount of gelsolin, in excess of that required to dissolve actin gels, was used to render the polypeptide visible on stained polyacrylamide gels. Because of this excess, some of the added gelsolin remained in the supernatant. Furthermore, less actin sedimented in these conditions, and any gelsolin which might be bound to the non-sedimented actin would also remain in the supernatant. In the presence of EGTA, less than 20% of the gelsolin sedimented with actin, even though more actin was pelleted (Table 2, lines 6, 8). The ratios of pelleted gelsolin to actin were therefore much lower in the EGTA-treated samples than the calcium-treated samples.

These experiments have shown that gelsolin bound to actin in a Ca^{2+}-dependent manner, and decreased the viscosity and sedimentability of actin in the absence of cross-linking proteins. Inhibition of actin gelation by gelsolin may therefore be mediated by a direct effect of gelsolin on actin filaments. To explain complete inhibition of actin gelation following limited decrease in actin viscosity and sedimentability, we propose that gelsolin divides actin filaments between cross-linking points, thereby increasing the number of filaments. This mechanism of disrupting cross-linked networks is consistent with the established theory for polymer gels, which predicts that small changes in the cross-linker to polymer ratio near a critical point can abruptly effect sol–gel transformations[19]. Actin ABP and actin–filamin networks behave in accordance with this theory[12,20]. If gelsolin divides actin filaments, and the number of cross-links remains the same, the resulting increase in number of filaments effectively lowers the cross-link : polymer ratio, and causes dissolution of actin gels. The small number of gelsolin molecules required to inhibit gelation of actin is consistent with the idea that gelsolin can dissolve actin gels by causing a few breaks in actin filaments.

Our findings demonstrate that gelsolin, a heat-labile protein isolated from macrophages, dissolves actin networks in association with the limited breakdown of actin filaments. The expression of the regulatory function of gelsolin depends on variation in free calcium concentrations likely to occur in living cells. This is the first report of successful reconstitution of a Ca^{2+}-controlled actin gelation system from purified proteins, similar to that described in cytoplasmic extracts from diverse sources. We conclude that gelsolin is a physiological calcium-dependent regulator of macrophage cytoplasmic structure.

Neurectoderm markers retained in phenotypical skeletal muscle cells arising from a glial cell line

Vanda A. Lennon & Susan Peterson

Neuroimmunology Laboratory, Departments of Neurology and Immunology, Mayo Clinic and Medical School, Rochester, Minnesota 55901

David Schubert

Neurobiology Laboratory, Salk Institute for Biological Studies, San Diego, California 92112

Differentiation *in vitro* of striated muscle from apparently non-muscle precursor cells has been reported in thymus reticulum[1], a fibroblast-like mouse embryo line[2] and in a neurone-like cell line derived from a rat brain tumour[3]. Also Tomozawa and Sueko reported the differentiation of a peripheral neurotumour clonal stem cell line into separate neuronal and glial cell types[4]. We report here the reproducible and stable phenotypic change of a well characterised rat glial cell line, B_9 (refs 5–7), into multinucleate contractile skeletal muscle. The B_9 line was derived from a nitrosoethylurea-induced brain tumour, contains S-100 and 14-3-2 proteins, is electrically non-excitable[5] and has a putative glial-specific surface antigen, G2 (ref. 6). It has been phenotypically stable in its laboratory of origin at Salk Institute since 1973. After being transported to the Mayo Clinic in Minnesota the cells began to change from cuboidal to elongate shape, fuse into contractile multinucleate fibres and express nicotinic acetylcholine receptors (AChR) on their plasma membranes. Striated myofibrils appeared in their cytoplasm. The first sign of mesectodermal differentiation in B_9 was the transitory appearance on its surface of Thy-1 which, in the rat, is a marker of thymocytes[8], certain brain cell lines[7], immature skeletal muscle[9,10], mammary myoepithelial lines[11] and fibroblasts[12]. This antigen was not detected in previous studies at Salk Institute[7]. The inductive influence is not yet known. We propose that transformation of a neurectodermal line into muscle may be evidence of the capacity of mammalian neurectoderm to give rise to skeletal tissues. The concept that skeletal muscle in different anatomical regions might have different embryonic origins could be relevant to the distribution of muscles affected by certain diseases in man.

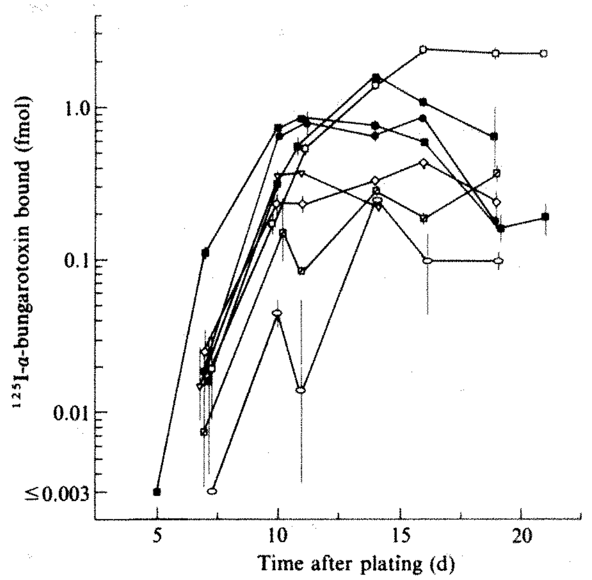

Fig. 1 Quantitation of nicotinic ACh receptors (AChR) on rat cell lines grown in microculture (2×10^3 cells in 0.2 ml DMEM/FCS, Microtest II plates, Falcon). Specific binding of α-bungarotoxin (α-BT, prepared and labelled with 5 mCi ^{125}I per 100 μg as described elsewhere[22]) was measured at multiple time points as follows. DMEM was withdrawn and 12 replicated wells washed once with HEPES-buffered DMEM (HBM) with 5% FCS. To 6 of the 12 wells was added 0.2 M carbamylcholine (CC). After 20 min at 21 °C an excess of ^{125}I-α-BT (4×10^{-9} M) was added to all 12 wells. Fluid was withdrawn after 90 min and the wells were washed three times with HBM/FCS, then one drop of 1 M KOH was added to each. After 15 min, the wells were swabbed with cotton-tipped applicators which were transferred to glass tubes for γ counting. Specific binding sites for ^{125}I-α-BT were calculated as: (mean c.p.m. without CC) − (mean c.p.m. with CC) × (mol standard ^{125}I-α-BT/c.p.m. standard ^{125}I-α-BT). Demonstration of antigenic determinants of nicotinic AChR in association with an α-BT binding macromolecule, extracted in non-ionic detergent from B_9M (subclone 33), distinguished this AChR from that of sympathetic ganglia type AChR[14]. Washed B_9M no. 33 cells (grown for 15 d in dishes of 150 cm^2 area) were extracted with 3% Triton X-100 (in 10 mM Tris, 100 mM NaCl, 1 mM EDTA, 5×10^{-4} M NaN_3 and 5×10^{-5} M PMSF). In the presence of an excess of ^{125}I-α-BT, a macromolecule binding α-BT was quantitated by chromatography on Sephadex G-100 (yield 2.34 fmol per cm^2 plate), as well as by precipitation from Triton X-100 extract[22] by sequential addition of rat antibodies against *Torpedo* electric organ AChR and goat anti-rat Ig (yield 2.18 fmol per cm^2 plate). Cell lines shown include: ●, L6 (mesenchymal muscle); ■, B_9M (B_9-derived; muscle phenotype) and six subclones of B_9M: ▽, 13 (predominantly cuboidal; thin myotubes); ○, 15 (mixed, elongate and cuboidal); ◇, 20 (mixed, cuboidal and elongate; large myotubes); ▨, 27 (predominantly cuboidal; less fusion of elongates); ☒, 31 (mixed elongate and cuboidal; many multinucleate myotubes); □, 33 (predominantly elongate, large myotubes). Glial cell lines B_{92} and B_9 are not shown, as they had no significant α-BT binding at any time (<0.01 fmol per well).

Glial lines B_9 and B_{92} (ref. 5) and a myogenic line, L6, from rat limb muscle[13], were transported by air at room temperature in plastic flasks containing Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal calf serum (FCS), penicillin G and streptomycin. B_9 and L6 were collected by Viokase treatment (20%, 37 °C, 15 min), and passaged every 7 days at low density (1.5×10^4 cells) in no. 3002 dishes (Falcon Labware) containing 5 ml DMEM with 10% FCS, penicillin G (20 U ml^{-1}) and streptomycin (0.02 mg ml^{-1}). B_{92} was collected by vigorous pipetting and similarly passaged. After the 7th passage, at 37 °C in humidified 12% CO_2/88% air, confluent cultures of B_9 were noted to have changed from cuboidal to fusiform shape. Many cells had fused to form multinucleate, vigorously contracting myotubes. At that time the laboratory had not received L6 or any other myogenic cell line. The changed cell line was renamed B_9M. Some cells were sent to California for continued passage and observation of phenotype; their progeny retained the skeletal muscle morphology on return to the original laboratory environment. Fresh stock of B_9 was sent from California for reference testing with B_9M and samples were cryopreserved after one subculture. After two passages in the new environment (with a different preparation of FCS) the second shipment of B_9 similarly became elongate and expressed pharmacological and antigenic markers of skeletal muscle (described below).

Cloning of B_9M at limiting dilution yielded 36 subclones (plating efficiency 47%). All were initially cuboidal; some became elongate and fused to form contractile myotubes; some remained predominantly cuboidal, but at high density all developed into a mixture of elongate and cuboidal. Specific binding sites for α-bungarotoxin (α-BT, indicative of AChR) were demonstrated on B_9M and on subclones of differing

β-Alanine	1.9; 2.3	2.1; 3.0	<0.1; <0.1

Analyses are expressed as residues per 1,000. Free amino acids were extracted as trichloracetic acid-soluble residues from two separate preparations of each cell line in the exponential growth phase as described previously[16]. The content of GABA and β-alanine in B_9 and B_9M is characteristic of neurectodermally derived cells; lack of these two amino acids in L6 is characteristic of cells of mesodermal origin[16]. Although significant differences are apparent in the content of several other amino acids in the B_9 and L6 lines, these differences are not found consistently between other cells of neurectodermal and mesodermal origin.

morphology (Fig. 1). Subclones giving rise to abundant myotubes bound more α-BT. Myotubes of no. 33 were widest in diameter and in repeated experiments this subclone had approximately four times more AChR than the standard muscle line L6. Neither glial line B_{92} nor the original B_9 bound ^{125}I-α-BT. Demonstration of antigenic determinants of skeletal muscle-type AChR in association with an α-BT-binding macromolecule extracted from B_9M (Fig. 1 legend) distinguished this receptor from that of sympathetic ganglia-type AChR[14].

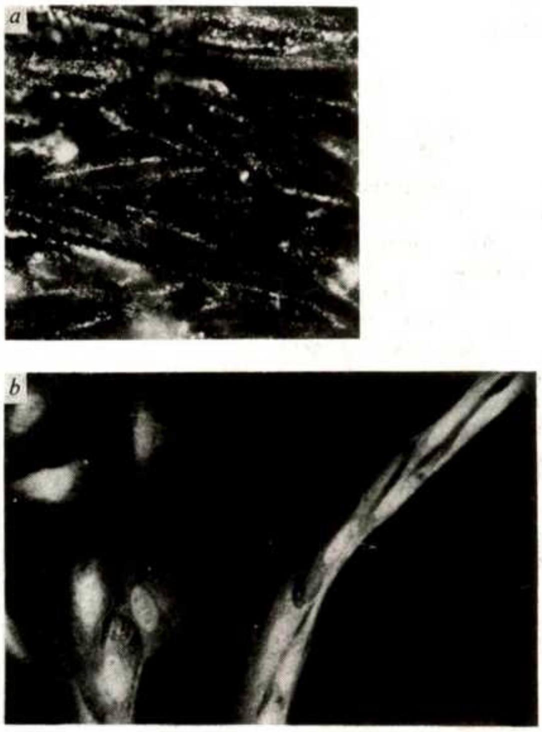

Fig. 2 For assay of Thy-1 by indirect immunofluorescence, cells were plated at 10^4 ml^{-1} into Petri dishes (1005, Falcon) containing round glass coverslips (no. 1 CGS, Propper Manufacturing Co.). ATS was used at a dilution of 1/50 followed by goat anti-rabbit IgG at 1/200 (Cappel Laboratories). *a*, In the living state the surfaces of elongate forms of subclone 33 of B_9M were Thy-1 positive. The characteristic coarse speckling of Thy-1 glycoprotein on developing myotubes in 10-day cultures is most prominent on cells of narrow diameter (×1,512). *b*, Acetone fixation revealed immunoreactive Thy-1 in the cytoplasm of cuboidal forms of the parental B_9M line and in aligned elongate pre-fusion cells 72 h after plating. Thy-1 glycoprotein is concentrated in the region of the nucleus in cuboidal forms and is more uniformly distributed in elongate forms (×1,512).

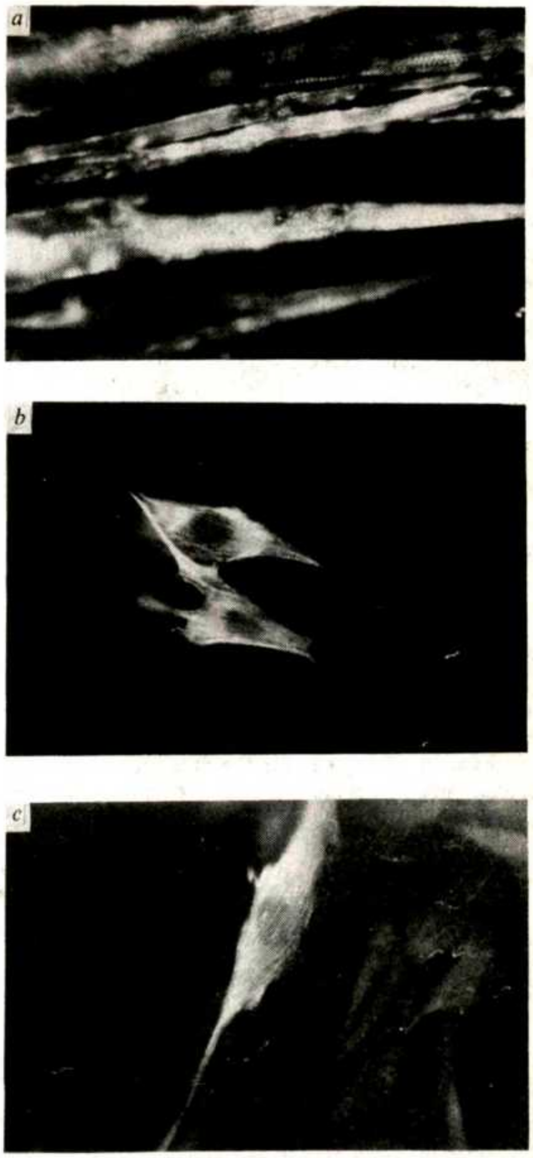

Fig. 3 Striated myofibrils characteristic of skeletal muscle were demonstrated in cytoplasm using serum (dilution 1/100) containing spontaneous autoantibodies reactive with contractile elements of skeletal muscle (obtained from a patient with myasthenia gravis). Indirect immunofluorescence used fluoresceinated goat anti-human IgG (Cappel Laboratories). *a*, Multinucleate L6 myotubes after 10 days in culture (×1,512); *b*, two aligned elongate B_9M cells after 72 h in culture (×1,512); *c*, positive elongate B_9M cell contrasts with negative background cells of more cuboidal morphology after 72 h in culture (×1,512).

Thy-1 glycoprotein was detected by indirect immunofluorescence using rabbit anti-rat thymocyte serum (ATS) described elsewhere[9]. No cell line exhibited fluorescence with ATS which had been absorbed by rat brain. In earlier studies of L6 and primary rat muscle cultures[9] we found Thy-1 on the surface of myoblasts and myotubes in early stages of fusion, but not on multinucleate myotubes. In the present study, L6 myoblasts, elongate forms of B_9M and its subclones and cuboidal cells contiguous with elongate forms were unequivocally positive (Fig. 2*a*). Acetone fixation revealed immunoreactive Thy-1 in the cytoplasm of cuboidal forms of B_9M (Fig. 2*b*). Small myotubes of B_9M and its subclones were most strongly positive for Thy-1; Thy-1 fluorescence on intermediate-sized myotubes was reduced (Fig. 2*a*) and multinucleate forms in 10-day cultures lacked detectable Thy-1. Recently transported B_9 lacked Thy-1, but after several passages, a few elongate Thy-1-positive cells appeared on top of the Thy-1-negative cuboidal monolayer.

Sera from certain patients with myasthenia gravis contain antibodies which react with contractile elements of striated muscle[15]. A myasthenia gravis patient's serum with this reactivity revealed cytoplasmic filaments in some mononucleate B_9M and L6 cells and striated myofibrils in multinucleate myotubes of both lines (Fig. 3). B_9 was negative for myofibril antigen.

Intracellular γ-aminobutyric acid (GABA) and β-alanine are found in cell lines derived from neurectoderm but not in cells derived from mesoderm[16]. To determine whether B_9M retained this neurectodermal marker, exponentially growing B_9, B_9M and L6 cells were analysed for free amino acids[16] (Table 1). B_9M and B_9 had very similar free amino acid compositions, but these differed appreciably from L6; B_9M and B_9 contained significant amounts of GABA and β-alanine whereas L6 characteristically lacked these two amino acids. Thus, the phenotypically changed B_9 metabolised amino acids in a manner similar to its parental cell line but distinct from mesoderm-derived skeletal muscle.

Experimental observations in lower vertebrate embryos indicate that certain mesenchymal elements of the head and neck arise from neural crest[17,18]. By grafting neural crest cells between quail and chick, LeLievre and LeDouarin[18] established that crest cells of the cephalic neural axis down to the 5th somite can give rise to mesenchymal derivatives (including skeletal muscle). If mammalian cephalic neurectoderm can also give rise to mesenchyme, this may explain the rare occurrence of striated muscle elements in primary tumours of the central nervous system (CNS) in man[19], and the derivation of clonal cell lines of skeletal muscle phenotype from tumours induced chemically in developing rat CNS (ref. 5, and D.S., unpublished observation). Rarely, tumours of skeletal muscle arise in the thymus[20], which is a pharyngeal pouch derivative. Thymic mesenchyme is predominantly neural-crest derived[21] and it is likely that its skeletal muscle elements[22,23] are also of neural crest origin. The thymus is prominently involved in the immunopathology of myasthenia gravis; it is probably the major site of autoimmunisation against AChR which is the cause of failure of neuromuscular transmission in this disease[23]. If AChR of thymic myogenic cells and cranial muscle were to share antigenic determinants unique to AChR of neurectodermal origin, the head and neck muscles, which are commonly involved in myasthenia gravis, might be the preferential targets of circulating antibodies with specificities restricted to neurectodermal determinants of AChR. Our observation of skeletal muscle differentiation from a neurectodermal cell line of rat suggests that the cephalic neural crest of mammals, like that of lower vertebrates[17,18], might have myogenic potentiality. It remains to be determined whether mammalian neurectoderm contributes to skeletal structures of the head and neck in normal histogenesis.

This work was supported by grants from the Muscular Dystrophy Association (V.L. and D.S.), the NIH (NS 15057, V.L.) and the Kroc Foundation, Santa Ynez, California (V.L.).

Note added in proof: Striated muscle fibres are known to exist in normal pineal glands, including human[24]. Recent documentation of the electrophysiological and pharmacological properties of skeletal muscle fibres arising from primary cultures of rat pineals[25] further supports our hypothesis of the myogenic potentiality of mammalian neurectoderm.

The production of the arachidonate metabolite HETE in vascular tissue

James E. Greenwald, Joseph R. Bianchine & Lan K. Wong

Department of Pharmacology, The Ohio State University, College of Medicine, Columbus, Ohio 43210

Blood platelets contain two enzyme systems which oxygenate arachidonic acid (AA). First, a cyclooxygenase[1] which metabolises AA into the biologically active prostaglandin endoperoxides (PGG_2 and PGH_2) which are precursors for the platelet prostaglandins PGE_2, $PGF_{2\alpha}$ and thromboxane A_2 (TxA_2). And second, a lipoxygenase that metabolises AA into 12-*L*-hydroperoxy-5, 8, 10, 14-eicosatetraenoic acid (HPETE)[1,2]. HPETE is a labile intermediate which is nonenzymatically reduced in aqueous environments to a more stable metabolite, 12-*L*-hydroxy-5, 8, 10, 14-eicosatetraenoic acid (HETE). HPETE is produced in significant quantities by aggregated platelets, but its exact biological role is not known. Turner *et al.*[3] has suggested that HETE may be a mediator of neutrophil chemotaxis. Vane and coworkers demonstrated that 15-hydroperoxy-5, 8, 10, 14-eicosatetraenoic acid[4,5] as well as HPETE were potent inhibitors of prostacyclin (PGI_2), the major arachidonate metabolite in vascular tissue. These data suggest that HPETE, if present in vascular tissue, might act as endogenous regulator of PGI_2 production. Using radiochemical techniques and mass spectrometry we have now identified a lipoxygenase enzyme in vascular tissue (rabbit aorta) in which biosynthesis of HETE also occurred. The detection of HETE in this suggests a potential role of the lipoxygenated product as an endogenous regulator of PGI_2 biosynthesis.

Rabbit aorta was cut into small rings (3–5 mg wet weight) and incubated with ^{14}C-labelled AA at 37 °C for 5 min. After incubation, the reaction medium was acidified with 1.0 M formic acid and extracted with ethyl acetate. The radioactive products were partitioned into the organic phase which was then evaporated to dryness under nitrogen. The products were resuspended in ethyl acetate/methanol (1 : 1) and subjected to TLC.

As shown in Fig. 1*a* and *c*, initial incubations of aortic rings yielded an unknown radioactive peak with an R_F value very similar to ricinoleic acid when developed in solvent system I or solvent system II. In a second experiment, indomethacin at a concentration (10^{-4} M) which completely inhibits the cyclooxygenase enzyme was added to the incubation medium, and production of this unknown arachidonate metabolite was stimulated by 50% (Fig. 1*b*, Table 1). From these data it can be concluded that this compound is not a cyclooxygenase product.

AA is prone to nonenzymatic oxidation and this mechanism might account for the unknown component. To differentiate between nonenzymatic and enzymatic oxidation of AA, aortic rings were preincubated with eicosatetraenoic acid (ETYA),

Table 1 Effects of inhibitors on HETE production in rabbit aorta

Inhibitors	HETE (pmol)	% Change from control
—	125.47*	+55
Indomethacin (1×10^{-4} M)	194.31*	
—	107.86†	−61
ETYA (1×10^{-4} M)	42.08†	
—	149.18‡	−48
PCMB (2×10^{-3} M)	78.03‡	

* An average of three animals.
† An average of two animals.
‡ An average of five animals.

which inhibits both lipoxygenase and cyclooxygenase[1]. As shown in Table 1, ETYA (10^{-4} M) completely blocked the formation of this compound, suggesting an enzymatic (lipoxygenase) pathway for the formation of this unknown compound.

If the unknown were HETE, selective inhibition of lipoxygenase would be expected to abolish the formation of this compound and desuppress the biosynthesis of PGI_2. Nugteren[6] found that para-chloromercuribenzoate (PCMB) was a selective inhibitor of human platelet lipoxygenase at 2×10^{-3} M. In our studies, incubation of PCMB (2×10^{-3} M) with aortic rings (Fig. 1*d*, Table 1) caused 50% inhibition of formation of the unknown compound, but no stimulation of PGI_2. PCMB tested at various concentrations with lipoxygenase from washed human platelets did not selectively inhibit HETE production—PCMB at 2×10^{-3} M inhibited formation of both HETE and PG (data not shown).

We further characterised the unknown component by gas chromatography–mass spectrometry (GC–MS) analysis. The TLC zone of interest was scraped and eluted with methanol. This extract was concentrated and derivatised with diazomethane followed by trimethylsilylation[1]. The sample was then analysed by selected ion monitoring on a Hewlett Packard model 5985 GC-MS system. Characteristic ions of HETE at *m/e* 391 (M-15), *m/e* 295 (base peak) and *m/e* 225 were observed at the expected retention time. These data show the unknown component to be HETE.

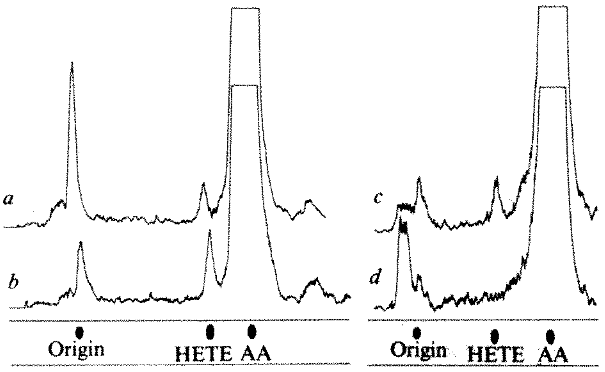

Fig. 1 TLC radiochromatograms of arachidonic acid metabolites in rabbit aorta. Rabbits (2–4 kg) were each given intravenously 1,000 units of sodium heparin to avoid blood clotting and anaesthetised with sodium pentobarbital. The animals were killed and their aortas excised and cut into small rings (4–5 mg per ring) in 50 mM Tris-HCl (*p*H 7.5) at 4 °C. Each incubation was carried out on 80–90 mg tissue with 7 nmol ^{14}C-labelled AA and 0.5 ml *p*H 7.5 Tris buffer in the presence or absence of a drug. The incubation was allowed to proceed for 5 min with shaking at 37 °C in a waterbath. Then the reaction was quenched with 1.0 M formic acid, extracted twice with three times its own volume of ethyl acetate and subjected to TLC. Authentic standards of PG and fatty acid were chromatographed in parallel with unknowns. Zones of radioactivity were detected by a Packard radioscanner and by iodine vapour visualisation. The zones were collected for liquid scintillation counting. *a*, An incubation in the absence of any drug using TLC system I (chloroform/methanol/acetic acid, 60:40:3). *b*, An incubation in the presence of 1×10^{-4} M indomethacin using TLC system I. *c*, An incubation similar to *a* but using TLC system II (ethyl acetate/2,2,4-trimethylpentane/water, 75:75:100). *d*, An incubation in the presence of 2×10^{-3} M PCMB using TLC system II.

Since the intermediate HPETE is an inhibitor of PGI_2 biosynthesis, the lipoxygenase enzyme in rabbit aorta may have a role in modulating PGI_2 production in vasculature. A high activity of lipoxygenase would suppress PGI_2 formation and result in vasoconstriction, and a low level of lipoxygenase would favour PGI_2 biosynthesis and cause vasodilation. Our findings suggest a physiological role of the lipoxygenase in the cardiovascular system.

We thank the Central Ohio Heart Chapter of the American Heart Association for support (grant no. 79-40 to Lan K. Wong).

Tumour promoter induces anchorage independence irreversibly

Nancy H. Colburn, Brigitte F. Former, Katherine A. Nelson & Stuart H. Yuspa

In Vitro Pathogenesis Section, Laboratory of Experimental Pathology, National Cancer Institute, Bethesda, Maryland 20014

Tumour-promoting phorbol esters elicit a variety of molecular responses from cells in culture[1–3]. Phorbol esters are also active as promoters of neoplastic transformation in 10T1/2 mouse fibroblasts, previously initiated by polycyclic aromatic hydrocarbons[4] or UV[5] or X-ray irradiation[6]. As many *in vivo* studies of the tumour-promoting activity of phorbol esters have been carried out in mouse skin[7], it seems desirable to use mouse epidermal cell lines to study the mechanism of tumour promotion *in vitro*. Mouse epidermal cell lines would be particularly useful if they responded to phorbol esters by progressing towards a neoplastic phenotype. We have previously reported the development of cell lines derived from primary mouse epidermal cultures after carcinogen or solvent exposure[8]. Some of these cell lines remained non-tumorigenic for many passages and failed to form colonies in soft agar (frequency less than 10^{-4})[9]. We next asked whether some of these non-tumorigenic cells might respond to tumour promoters like 'initiated' or 'post-initiated' cells *in vivo* by progressing towards a neoplastic state[9,10]. We report here the identification of three epidermal cell lines which respond to tumour-promoting but not to non-promoting phorbol esters by irreversibly acquiring capacity to grow in soft agar. As anchorage-independent growth characterises malignant cells derived from a variety of sources including mouse epidermis[8,11], this response to phorbol esters may be analogous to a late stage of tumour promotion *in vivo*.

Primary epidermal cell cultures[12] were prepared from newborn BALB/c mice[8] or non-inbred Sencar mice[9] which had been bred for sensitivity to a 7,12-dimethylbenz (*a*) anthracene (DMBA)/12-*O*-tetradecanoyl phorbol-13-acetate (TPA) initiation-promotion scheme of skin carcinogenesis[13]. Cell lines were derived after exposure to carcinogen or to solvent alone as previously described[8,9]. All of these cell lines retained epidermal-specific cell-surface antigen (N.H.C. *et al.*, in preparation).

Table 1 Induction of growth in 0.33% agar medium after exposure to TPA

		No. of colonies per 10^4 cells			
		10% Serum		20% Serum	
Cell line	Initial treatment	Solvent control	TPA	Solvent control	TPA
JB-6	Solvent	<1	696	84	3888
D-2	DMBA	<1	24	84	756
JB-10	MNNG	<1	72	36	264

JB-6 and JB-10 cell lines were derived from solvent or MNNG-treated BALB/c primary cultures as described previously[8,9]. The D-2 line was derived from DMBA-treated (0.01 μg ml^{-1}, twice a week for 3 months) Sencar primary cultures. Cells were grown in monolayer culture in Eagle's minimal essential medium containing 10% fetal calf serum (FCS) and antibiotics and replated once a week[8]. Cells were suspended in 0.33% Difco agar medium[8] containing solvent alone (0.1% DMSO) or TPA at 0.1 μg ml^{-1} (1.6×10^{-7} M) and layered at 10^4 cells per 60-mm dish over a 0.5% agar base. The temperature of agar medium when mixed with phorbol esters was less than 40 °C. Assays were carried out in duplicate at both 10% and 20% FCS concentrations without refeeding and colonies were counted at 14 days. Cells were assayed at the following passages: JB-6: 35–51; D-2: 10–24; JB-10: 31–39. Each value is the mean for 3 to 8 separate experiments in which the s.e.m. ranged from 5 to 15% of the value.

While some lines were tumorigenic and formed colonies in 0.33% agar[8], others failed to grow in agar (in 10% serum) for at least 39 passages[8,9]. Twenty-one lines of the latter group were screened for colony formation in agar in response to tumour promoters. Three responders were identified including BALB/c lines JB-6, initially exposed only to solvent[8], and JB-10, initially exposed to *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG)[8]; and a Sencar line D-2, initially exposed to DMBA (N.C., unpublished). As with all anchorage-dependent mouse epidermal lines tested so far, JB-6 and JB-10 did not give rise to tumours after injection into syngeneic newborns at passages 57 and 15 respectively (refs 8, 9 and unpublished).

When exposed to the tumour-promoting phorbol ester TPA in agar medium, these three non-tumorigenic cell lines showed anchorage-independent growth (Table 1). Colony induction occurred at serum concentrations of 10% and 20%, with greater sensitivity for detection of induced colonies and higher background at 20% serum. This background may reflect weak colony inducing activity of serum growth factor(s) in agar medium. One growth factor, epidermal growth factor (EGF), has been reported to enhance skin tumour yield in 3-methylcholanthrene-treated mice[14]. Recent results (unpublished) have shown that EGF and sarcoma growth factor of Todaro and coworkers[15] will induce growth in agar by JB-6 cells. Previous findings indicated that epidermal cell lines which formed colonies at frequencies less than 1 per 10^4 in 10% serum in soft agar consistently turned out to be non-tumorigenic[8,9]. In contrast, tumorigenic lines usually formed colonies at frequencies greater than 200 per 10^4 in 10% serum. Hence, it seems likely that this TPA-dependent increase in anchorage independence represents induction of tumour cell phenotype. Of the three cell lines, JB-6 showed the highest response to TPA with 39% of the cells giving rise to colonies in 20% serum. To acquire this responsiveness, the JB-6 line required some 30 or more passages in culture. Cells from earlier passage (for example 18, 20, 28) showed no detectable response to TPA in agar (data not shown). Thus whatever 'initiation' or post-initiation events occurred in this solvent-treated line, they did so independently of exposure to added carcinogen and required considerable time in culture. In contrast the TPA responsiveness of D-2 and JB-10 appeared in earlier passages (10 and 15 respectively) and may have resulted from carcinogen exposure during primary culture (see Table 1).

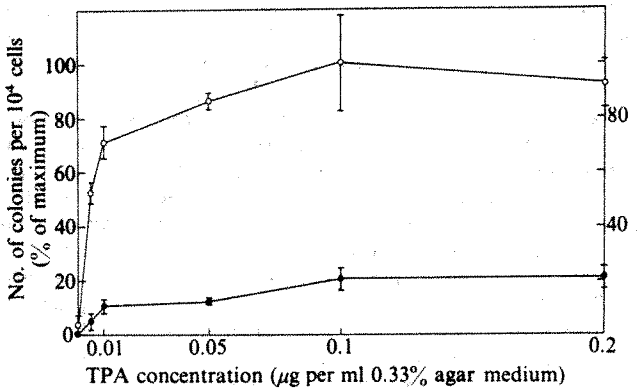

Fig. 1 Effect of TPA concentration on colony formation in soft agar. Assay of growth in 0.33% agar medium was carried out as described in the Table 1 legend. TPA concentration ranged from 0.005 to 0.2 μg ml^{-1} (8×10^{-9} M–3.3×10^{-7} M). JB-6 cells were assayed at passages 35 to 51. Each point represents the mean of 4 to 16 experiments. Vertical bars indicate s.e.m. Colony forming efficiency is expressed as a per cent of the maximum induced value (that obtained with 0.1 μg ml^{-1} TPA in 20% serum). This form of expression allows the combining of data from a number of experiments as colony forming efficiency varies with serum batch (unpublished). ●, 10% serum; ○, 20% serum.

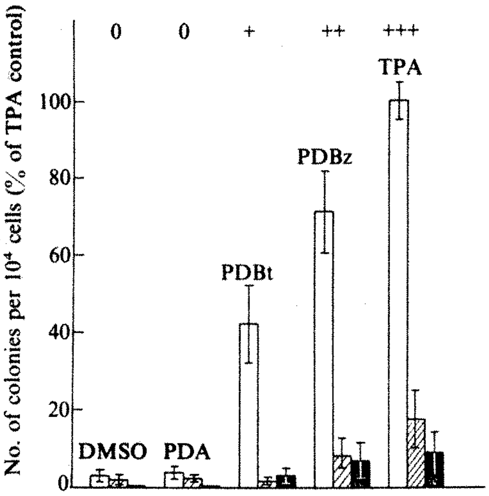

Fig. 2 Correlation of colony inducing activity with tumour-promoting activity of phorbol esters. Assay of growth in 0.33% agar medium was carried out as described in the Table 1 legend. All phorbol esters were used at a concentration of 0.1 μg per ml agar medium and a dimethyl sulphoxide (DMSO) concentration of 0.1%. The rank ordering of tumour-promoting activity of phorbol esters indicated by 0 to +++ is based on Baird and Boutwell[16]. Open bars: JB-6, 20% serum. Shaded bars: D-2, 20% serum. Solid bars: JB6, 10% serum. PDBz, phorbol-12,13-dibenzoate; PDBt, phorbol-12,13-dibutyrate; PDA, phorbol-12,13-diacetate; DMSO, dimethyl sulphoxide control.

Figure 1 shows the dependence of colony induction on TPA concentration. TPA at concentrations from 0.005 to 0.2 μg ml^{-1} induced colony formation with maximum induction occurring at 0.1 μg ml^{-1} (1.6×10^{-7} M). The dose–response curves are of similar shape in 10% or 20% serum but absolute colony forming efficiency is 4–5-fold higher in 20% serum. TPA at a concentration as low as 10^{-10} M has been found to induce colony formation in JB6 cells grown in agar medium containing 20% serum (data not shown).

Figure 2 indicates that other tumour-promoting phorbol esters but not non-promoting phorbol esters induced anchorage-independent growth in JB-6 and D-2 cells. For JB-6 at 20% or 10% serum the order of colony inducing activity was as follows: TPA > phorbol dibenzoate > phorbol dibutyrate, with the non-promoter phorbol diacetate showing no inducing activity (values identical to solvent control). In D-2 cells only TPA and phorbol dibenzoate induced colony formation. The colony inducing activity paralleled the tumour promoting activity reported for these phorbol esters by Baird and Boutwell[16].

Many changes induced by tumour-promoting phorbol esters in normal cells are transient and tend to mimic the neoplastic phenotype[17]. These changes include loss of cell-surface fibronectin[3] and induction of high levels of plasminogen activator[18] and ornithine decarboxylase[19–21]. Many of the phenotypic changes become permanent during pre-neoplastic progression at the time of conversion to overt malignancies often under the influence of promoters[22]. Thus if the TPA responsive cell lines represent a late stage in tumour promotion, one would expect promoter-induced anchorage independence to be irreversible.

After induction by TPA in agar, colonies were removed with a capillary tube and grown in monolayer culture to yield cell lines, each derived from a single agar colony. The cell lines were then suspended in 0.33% agar medium in the absence of TPA to determine whether the cells retained the capacity for anchorage-independent growth. As shown in Table 2, all of the 11 lines obtained formed colonies in soft agar at frequencies ranging from 96 to 1,992 per 10^4 cells in 10% serum and from 678 to 4,968 per 10^4 cells in 20% serum. Even the lower values were many times higher than those found for the untreated control. The original values obtained for colonies induced in the presence of TPA (TPA-treated control) are presented for comparison. The values for agar derived colonies ranged from 15% to 300% of the original TPA induced values and remained undiminished for at least 2 months following the colony isolation. Cell lines derived from the D-2 line (see Table 1) after induction of anchorage independence by TPA were also found to be stable for growth in soft agar (data not shown). The retained values for the D-2 derived lines were 7–11-fold higher than the original TPA-induced values. Retention of anchorage independence by TPA treated JB10 cells has not yet been tested.

The mechanism of the agar colony response to tumour promoters has yet to be elucidated. Studies in our laboratory (ref. 22, and manuscript in preparation) suggest that TPA induces a shift in anchorage independence rather than selecting for pre-existing anchorage-independent cells, as colonies form from single JB6 cells (plated one per well in soft agar) in response to TPA. Because induction of anchorage independence by tumour-promoting phorbol esters seems to occur rapidly and irreversibly in the JB-6 and D-2 epidermal cell lines, the process may be analogous to a late phase of tumour promotion *in vivo* in which TPA apparently converts benign premalignant lesions to malignant tumours irreversibly[22,23].

Table 2 Retention of anchorage independence in the absence of TPA

Cell line	Derivation Cells	Passage	No. of colonies per 10^4 cells 10% Serum	20% Serum
JB6		62–74	7	128
JB6 + TPA (0.01 μg ml^{-1})		62–74	649	2,073
T61	JB6	70	138	1,410
T62	JB6	70	1,992	3,504
T63	JB6	70	96	1,050
T64	JB6	70	824	2,784
T2111	JB6 C121	23	216	678
T2121	JB6 C121	23	852	3,594
T2122	JB6 C121	23	432	1,848
T2123	JB6 C121	23	162	1,632
T2124	JB6 C121	23	756	4,968
T2125	JB6 C121	23	1,050	2,796
T2126	JB6 C121	23	492	2,820

Cells were suspended in 0.33% agar medium as described in the legend to Table 1. Except for the TPA-treated controls (JB6 + TPA), all cell lines were grown in agar in the absence of TPA. Lines T61–T64 were derived from single colonies induced in soft agar after exposure of JB-6 cells to TPA (0.01 μg ml^{-1}) in 10% serum. Lines T2111–2126 were obtained from colonies produced after identical exposure of a clone derived (by growth from single cells in standard medium) from the JB-6 line, passage 50 and designated JB6 Clone 21. Cell lines derived from soft agar colonies were grown for 2 passages in monolayer culture (2–3 weeks) before assaying for retention of anchorage independence. Clone 21 yielded values for untreated controls and TPA-treated controls which were about 20% higher than the respective values for JB-6. Cell lines derived from background colonies (without TPA) in 20% serum retained colony forming frequencies similar to the original background levels shown. Each value is the mean for 2 experiments run in duplicate. The differences from earlier passages (Table 1) for solvent and TPA treated JB-6 controls may be attributable to a change in serum batch.

We thank Drs Katherine Sanford and Takeo Kakunaga for reviewing the manuscript and Lina De Leonibus for typing.

Tumour promoters enhance anchorage-independent growth of adenovirus-transformed cells without altering the integration pattern of viral sequences

Carcinogenesis often involves interaction between multiple factors and proceeds through several discrete steps[1–4]. In mouse skin two distinct phases, 'initiation' and 'promotion', have been described[2]. The most potent tumour-promoting agents in mouse skin are 12-*O*-tetradecanoylphorbol-13-acetate (TPA) and related diterpenes[3–5]. A significant experimental advance in studies on the mechanism of action of tumour promoters has been the demonstration that they induce specific biochemical and biological effects in cell culture[6–8]. These effects include phenotypic changes that mimic those seen during transformation; modulation of differentiation; enhancement of the expression of markers of transformation in cells that are already transformed; and an increased yield of transformed foci in cultures exposed to chemical carcinogens or radiation[6–11]. We have previously reported that TPA also increases the yield of transformed foci in rat embryo cultures previously infected with a mutant of type 5 adenovirus[12]. When foci of adenovirus-transformed cells are picked, cloned and serially passaged, they

0028–0836/79/420591—04$01.00

undergo progressive changes, the most notable of which is acquisition of anchorage-independent growth[13]. The present study demonstrates that although TPA enhances the acquisition of anchorage-independent growth in adenovirus-transformed cells (and not in normal cells), this alteration in growth properties is not due to a change in the integration pattern of adenovirus DNA sequences in the genome of the host cell.

Normal secondary rat embryo (2°RE) cultures were infected with a mutant of type 5 adenovirus, H5ts125. This mutant was used because at 37 °C it is defective in DNA replication and has a higher transforming efficiency than wild-type virus[14]. In some experiments, the cultures were exposed to chemical carcinogens just before virus infection[12]. Epithelioid foci characteristic of adenovirus transformation were picked 5 to 6 weeks later, cloned and then passed in serial culture[12,13]. The presence of adenovirus DNA sequences in all of the isolated epithelioid clones was demonstrated by reassociation kinetics of ^{32}P-labelled Ad5 DNA *Hin*dIII restriction fragments and excess unlabelled transformed cell DNA[15]. We found that during early passages (<10) these clones had a low or negligible capacity to grow in agar, whereas at later passages (>30); they spontaneously acquired the ability to grow in agar, although with varying cloning efficiencies[13].

Although TPA does not induce growth in agar of normal 2°RE cells, it causes an appreciable enhancement of the agar cloning efficiency of the adenovirus-transformed clones (Table 1). With certain early passage adenovirus-transformed clones, growth in agar was undetectable unless TPA was added. With later passages, these clones spontaneously acquired the ability to grow in agar but their growth in agar was significantly enhanced by TPA. Similar results were obtained with 14 other clones of adenovirus-transformed cells[13]. The E11-E (assayed before 10 serial passages) and E11-L (assayed after 30 serial passages) clones have been studied in greater detail. Concentration curves demonstrated that 3 ng ml^{-1} was the optimal concentration of TPA (in agar) to effect anchorage-independent growth; a half-maximal effect was obtained with 1 ng ml^{-1} (1.6×10^{-10} M). Specificity of the TPA effect was demonstrated by the fact that 200 ng ml^{-1} of either phorbol or 4α phorbol-12-13-didecanoate (4αPDD), which are inactive as tumour promoters on mouse skin[3-5], failed to enhance growth in agar.

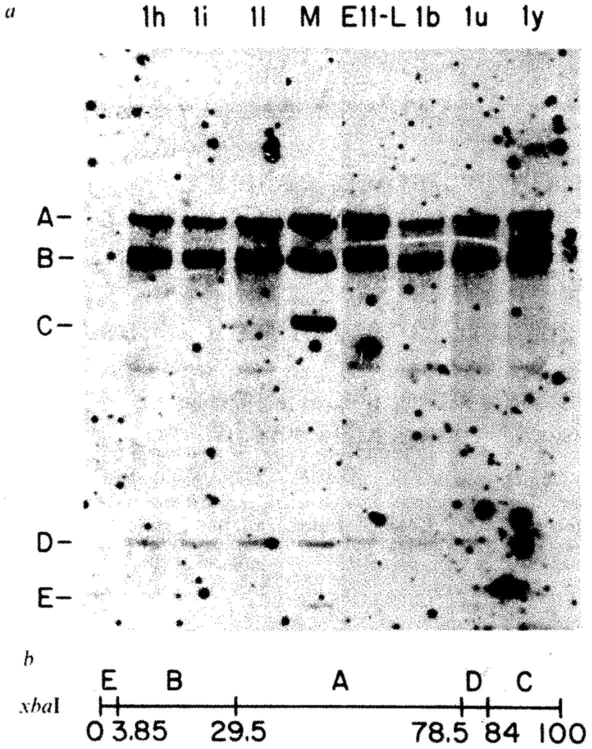

Fig. 1 *a*, Integration pattern of Ad5 DNA in a cloned population of H5ts125-transformed 2°RE cells (E11-L) and in subclones of E11-L isolated from agar either containing or lacking 100 ng ml^{-1} TPA. Confluent monolayers were grown from each subclone in low Ca^{2+} medium. DNA was isolated as described by Pellicer *et al.*[24] and 5 μg of DNA from each clone was cleaved with the restriction endonuclease *Xba*I. The DNA was electrophoresed in 0.7% agarose gels and then transferred to cellulose nitrate sheets according to a procedure slightly modified from the method of Southern[22]. Ad5 DNA labelled by nick-translation with ^{32}P to a specific activity of $2-4 \times 10^8$ c.p.m. per μg DNA[24] was used as a probe for filter hybridisation. The slot labelled M contains an artificial mixture of 5 μg DNA isolated from 2°RE cells and 5×10^{-5} μg purified Ad5 DNA cleaved with *Xba*I restriction endonuclease. The bands on the autoradiographs are identified as A–E. *b*, *Xba*I restriction map of Ad5 DNA.

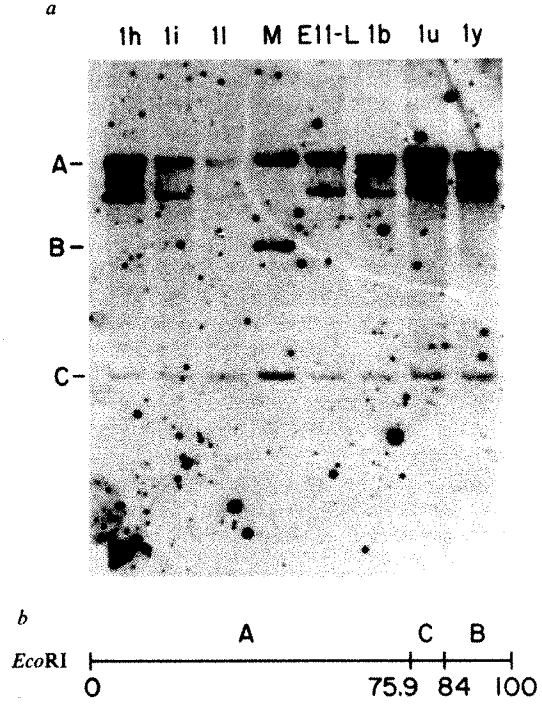

Fig. 2 *a*, Integration pattern of Ad5 DNA in a cloned population of H5ts125-transformed 2°RE cells (E11-L) and in subclones of E11-L. 5 μg of DNA was cleaved with *Eco*RI and hybridised with Ad5 DNA as described in Fig. 1 legend. The varying intensities of the bands in the different subclones from E11-L are due to uneven transfer of the DNA from the gel to the cellulose nitrate filter. The external B fragments migrated considerably more slowly than the corresponding marker B fragment. Note, however, that the external A fragments in transformed cell DNA did not appear to migrate more slowly than the corresponding A fragment of viral DNA because of the poor resolving power of the gel system in the region of the large A fragment (26.6 kilobase pairs). *b*, *Eco*RI restriction map of Ad5 DNA.

To determine whether or not the TPA enhancement of growth in agar was an irreversible effect, subclones of E11-L cells were isolated from agar lacking or containing TPA and further studied. Even in the absence of TPA these subclones grew with a 3.5- to 14.6-fold greater efficiency in agar than the parental clone (Table 1). Note that, with the exception of one subclone (E11-A-11), the addition of TPA to the agar resulted in a further enhancement (1.3- to 4.8-fold) in agar growth, and in some cases the cloning efficiency in agar than exceeded 50% (Table 1). Analysis of 14 additional E11-L subclones isolated from agar, which contained or lacked TPA, revealed that with serial passage in the absence of TPA none of these subclones reverted to the lower agar cloning efficiency characteristic of the parental E11-L clone. As with the parental E11-L clone, growth in agar of the subclones was not enhanced by 200 ng ml^{-1} of the non-tumour-promoting agents phorbol or 4αPDD.

When studied in monolayer culture, E11-L and all of its subclones had shorter average doubling times and higher saturation densities than normal 2°RE cells (Table 2). TPA did not significantly alter the average doubling time of normal 2°RE or any of the adenovirus-transformed clones (Table 2). TPA did, however, increase the saturation density of some, but not all of these cells. With serial passage E11 cells acquired a higher saturation density (compare E11-L to E11-E, Table 2) and, in general, the E11-L subclones derived from agar had higher saturation densities than the parental E11-L clone. However, there was no direct relationship between saturation densities and cloning efficiencies in agar of E11-L or its subclones, either in the absence or presence of TPA.

Previous studies have demonstrated that the transformation of Syrian hamster embryo cells following a single exposure to the carcinogen benzo(*a*)pyrene involves a series of progressive changes—morphological transformation, enhanced fibrinolytic activity, growth in agar and tumorigenicity[16,17]. These are acquired in a temporal fashion during repeated serial passage of the culture[16,17]. The acquisition of anchorage independence and tumorigenicity following the exposure of guinea pig embryo fibroblasts[18], rat brain cells[19], rat liver cells[20], or mouse epidermal cells[21], to a single exposure with chemical carcinogens has also been found to require extended serial passage (in these cases several months) in culture.

Table 1 Effect of TPA on anchorage-independent growth of normal and adenovirus-transformed rat embryo cells

Cell type	Colony number		Agar cloning efficiency (%)		TPA enhancement factor
	−TPA	+TPA	−TPA	+TPA	
2°RE	0	0	<0.001	<0.001	0
A18-E (<10 pass.)	0	2.4 ± 0.8	<0.001	0.1	>100
A18-L (>30 pass.)	2.8 ± 0.4	10.4 ± 2.2	0.1	0.5	5.0
E7-E (<10 pass.)	0	4.8 ± 2.0	<0.001	0.2	>200
E7-L (>30 pass.)	23.2 ± 2.4	54.4 ± 5.0	1.2	2.7	2.3
E11-E (<10 pass.)	22.2 ± 5.8	58.4 ± 6.4	1.1	2.9	2.6

Subclones of E11-L isolated from agar plus TPA					
E11 A-T-1 1b	826 ± 68.6	1,118 ± 72.4	43.1	55.9	1.3
E11 A-T-1 1u	232 ± 17.0	1,034 ± 72.2	11.6	51.7	4.5
E11 A-T-1 1y	245 ± 16.4	1,102 ± 96.6	12.7	55.1	4.3

Secondary rat embryo (2°RE) cultures were established from 14-d gestation Sprague–Dawley rat embryos[23] and were grown at 37 °C in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum (FBS). Clonal populations of type 5 adenovirus H5ts125-transformed 2°RE cells were formed as previously described[12] and were grown at 37 °C in 0.1 mM Ca^{2+} medium supplemented with 7.5% FBS (low-Ca^{2+} medium)[23]. Clones A18 and E7 were originally isolated from two foci (on different plates) of acetone pretreated (solvent control) H5ts125-transformed 2°RE cells and clone E11 cells were derived from a focus of benzo(*a*)pyrene (0.05 $\mu g\ ml^{-1}$)-pretreated, H5ts125-transformed 2°RE cells[12,13]. The original transformed cell population was cloned and tested for growth in agar followng early (E-, <10) and late (L-, >30) serial passage. E11-L subclones were isolated directly from agar lacking or containing 100 ng ml^{-1} TPA and were maintained as separate cell lines in low Ca^{2+} medium. Agar cloning efficiency of early (<10) and late (>30) passage adenovirus-transformed clones and E11-L subclones was determined by plating 2×10^3 cells in 4 ml of agar overlay medium containing 0.4% Noble agar prepared in low Ca^{2+} medium on top of prehardened 4-ml base layers consisting of 0.8% Noble agar in the same medium. Parallel cultures contained TPA at a final concentration of 100 ng ml^{-1} incorporated in both the agar overlay and base layers. Cultures were fed after 4 and 10 days with 3 ml of 0.4% Noble agar in low-Ca^{2+} medium containing or lacking 100 ng ml^{-1} TPA. Agar cloning efficiency of 2°RE cells in the presence or absence of 100 ng ml^{-1} TPA was determined as above except 2×10^4, 2×10^5 or 2×10^6 cells were seeded and the medium was DMEM in Noble agar. Colony number was determined by light microscopy after 14 days (colony size >0.1 mm) and 21 days (colony size >2 mm). Results reported are the average colony number from four replicate plates ± s.e.m. TPA enhancement factor refers to agar colony-forming ability in the presence of TPA relative to cultures not receiving TPA. Phorbol and 4α phorbol-12-13-didecanoate (4αPDD), two compounds inactive in tumour promotion, did not inhibit agar growth or induce enhanced agar cloning efficiency of any of the adenovirus-transformed clones even when tested at 200 ng ml^{-1}.

Experiments were therefore carried out to determine whether acquisition of anchorage independence following serial passage of adenovirus-transformed cells, or TPA treatment in agar, altered the amount or the pattern of viral DNA integration. Nucleic acid hybridisation techniques, reassociation kinetics[15], and Southern blotting filter hybridisation[22], were used to determine the amount of DNA present and the state of the DNA (that is, whether still integrated as single linear molecules). Reassociation kinetics indicated that E11-E and E11-L transformed cells each contained approximately one copy of the entire Ad5 genome. Furthermore, the Southern blotting technique revealed that the integration patterns of E11-E and E11-L were identical (data not shown) and that when the transformed cell DNA was cleaved with *Xba*I enzyme the integration patterns of viral DNA in E11-L and its subclones were indistinguishable (Fig. 1). Note that because of their attachment to host DNA, the terminal C and E fragments migrated more slowly than the C and E viral DNA marker fragments. Moreover, the C fragments of E11-L and all of its subclones co-migrated; similarly, all E fragments from E11-L and its subclones isolated from agar with or without TPA co-migrated with each other. In contrast, the internal fragments (A, B and D) from all clones co-migrated with the corresponding internal fragments of marker viral DNA, demonstrating that the viral DNA was integrated as intact linear molecules without interruption by cellular sequences and hence without disturbed specific endonuclease restriction sites. Similar conclusions can be drawn from patterns found following cleavage of transformed cell DNA with the *Eco*RI restriction endonuclease (Fig. 2).

The data presented here indicate that acquisition of anchorage-independent growth by adenovirus-transformed cells requires prolonged serial passage and that exposure to TPA markedly accelerates the acquisition of this property. These events are not due simply to random mutation and cell selection; their frequency is too high and they do not obey the properties of a classical mutation in a fluctuation analysis (P.B.F. and I.B.W., unpublished). In addition, the data presented indicate that these changes in cell phenotype are not due to alterations in the extent or state of integration of adenovirus sequences in the genome of the host cell. Two major alternatives remain to be considered: (1) a change in expression of the integrated viral sequences, either at the level of transcription and RNA processing or protein synthesis; or (2) alterations in the expression of specific host genes which might act in concert with integrated viral genes to modulate the phenotype of the transformants. We are now

Table 2 Effect of TPA on doubling time and saturation density of normal and adenovirus-transformed rat embryo cells

Cell type	Average population doubling		Saturation density (cells cm^2 × 10^5)	
	−TPA	+TPA	−TPA	+TPA
2°RE	32.2 ± 1.2	31.6 ± 1.5	1.7	2.1
A18-E (<10 pass.)	32.5 ± 1.0	29.5 ± 1.0	6.7	8.2
A18-L (>30 pass.)	19.4 ± 2.1	20.2 ± 1.7	8.7	9.9
E7-E (<10 pass.)	46.3 ± 3.5	45.7 ± 2.8	5.3	6.3
E7-L (>30 pass.)	21.4 ± 1.7	20.2 ± 2.1	7.9	9.5
E11-E (<10 pass.)	18.2 ± 1.0	15.4 ± 0.7	9.2	11.2

The average population doubling times and saturation densities of 2°RE and H5ts125-transformed clones in the presence or absence of TPA were obtained by plating 5 × 10^4 cells per 50 mm tissue culture plate in low-Ca^{2+} medium at 37 °C, changing the media after 6 or 24 h to low-Ca^{2+} medium with or without 100 ng ml^{-1} TPA and determining cell numbers over a 21-d period. Cells in triplicate plates were dispersed with trypsin/EDTA (0.25% trypsin w/v, 0.2% EDTA w/v) and counted every 24 h using a Coulter counter (Model Zf). The media were changed every 72 h with or without 100 ng ml^{-1} TPA. Population doubling times were calculated over a 72-h period corresponding to the logarithmic phase of growth. Saturation densities represent the maximum cell densities obtained in confluent cultures grown in the presence or absence of TPA.

analysing transcription patterns of viral mRNA in serially cultured clones of adenovirus-transformed cells, in the presence or absence of TPA, to determine whether changes in the type or amount of specific mRNA transcripts can be detected during the course of progression of these cell cultures. Thus, the cell system described here may be useful for understanding the mechanism by which transformed cells acquire anchorage-independent growth; it may also provide a useful model for studying the complex phenomena involved in tumour promotion and progression.

Lysozyme-induced T-suppressor cells and antibodies have a predominant idiotype

Michael A. Harvey, Luciano Adorini, Alexander Miller & Eli E. Sercarz

Department of Microbiology, University of California, Los Angeles, California 90024

The existence of shared idiotypic determinants on the surfaces of T and B cells is now firmly established, suggesting that on both these cell types immunoglobulin variable regions are expressed which presumably function as antigen receptors. In most systems this has been inferred through the use of anti-idiotypic antibody instead of antigen to induce either helper or suppressor T cells[1,2]. Recent evidence demonstrates that antigen-specific suppressor or helper factors can also bear idiotypic determinants[3,4]. It is possible that these factors represent released receptors or portions of receptors. We show here the direct elimination of an antigen-induced T-suppressor population by an anti-idiotypic serum and complement. These suppressor T cells as well as the idiotypic population used to generate the antiserum are each specific for the same limited portion of the multi-determinant antigen, lysozyme. Apparently, these suppressor cells are restricted in specificity as well as share idiotypy with antibodies of the same specificity.

Lysozymes are small (molecular weight ~14,300) globular proteins. The amino acid sequence and three-dimensional structure for lysozymes from many different species are known[5]. The murine response to a series of bird egg white lysozymes, typified by chicken lysozyme (HEL), is under H-2-linked genetic control. Mice of the H-2^b and H-2^s haplotypes (B10 and B10.S) are non-responders while mice bearing other haplotypes are responders[6]. We have demonstrated T-suppressor cells in

In vitro cell cultures were carried out using a miniaturised two-chamber diffusion culture system[14]. Culture medium was RPMI 1640 (GIBCO) supplemented with 10% fetal calf serum (Flow), 2 mM L-glutamine, 5 × 10^{-5} M 2-mercaptoethanol. B10 mice were primed intraperitoneally with CFA or HEL–CFA (100 μg per mouse) 4 weeks before culture. Spleen cells (2 × 10^6) were cultured together with 2 × 10^6 HEL-SRBC in 0.1 ml in the inner chamber, separated by a dialysis membrane from the reservoir in which 1.5 ml of medium was placed. At day 4 of culture, cells were collected and tested for direct PFC formation against HEL–burro (B)RBC, BRBC or sheep(S)RBC using the Cunningham and Szenberg technique[15]. Antiserum treatment: before culturing, 2 × 10^6 spleen cells were pelleted and resuspended in 0.1 ml of heat-inactivated normal guinea pig serum (NGPS) (final dilution 1 : 10) or guinea pig anti-idiotype (anti-id) (1 : 5) for 30 min at 4 °C. Cells were then washed once, resuspended in 0.1 ml rabbit complement (Cedarlane Low-Tox), diluted 1 : 8, incubated at 37 °C for 30 min and finally washed three times before culture. PFC data are presented as arithmetic means ± s.e.m. from three replicate cultures.

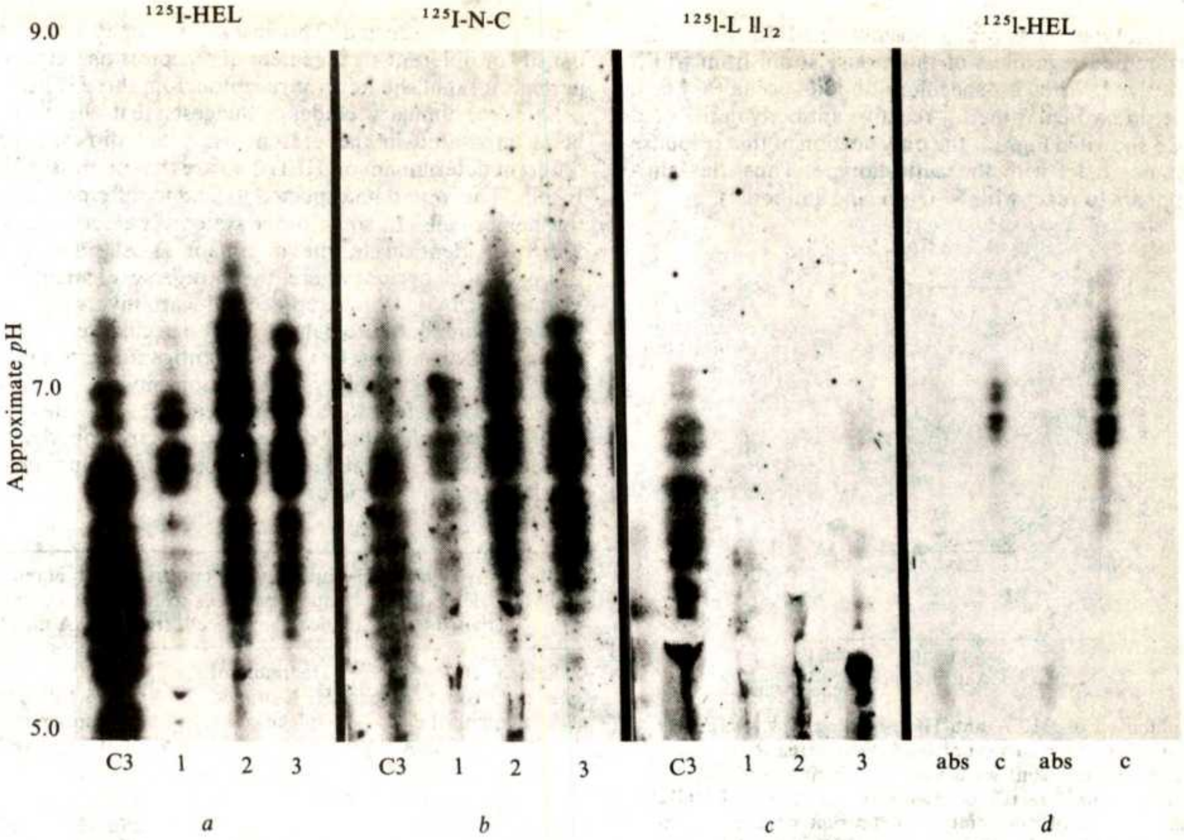

Fig. 1 Autoradiographs of isoelectric focusing in polyacrylamide gels showing specificity and idiotypy of anti-HEL antibodies. *a*, IEF patterns of 2 μl A/J C3 and B10.A (1, 2, 3) immune ascitic fluids, stained with ^{125}I-HEL. *b*, Same fluids as in *a* stained with ^{125}I-N–C peptide. *c*, Same fluids as in *a* stained with ^{125}I–L_{II} peptide. Isoelectric focusing was carried out as described previously[11]. Iodination of N–C peptide, which lacks tyrosine, was accomplished by first reacting the peptide with methyl-*p*-hydroxybenzimidate as described by Wood *et al.*[12], followed by iodination with the Chloramine T method[13], *d* Represents the effect of absorbing the anti-HEL from B10.A mice 1 and 3 with anti-idiotype before isoelectric focusing. Briefly, 2 μl of each B10.A anti-HEL was placed in a small conical centrifuge tube to which 10 μl guinea pig anti-idiotype was added. Control tubes were 2 μl ascitic fluid plus 10 μl normal guinea pig serum. All tubes were incubated for 30 min at 37 °C and overnight at 4 °C. The entire contents of each tube was then placed on isoelectric focusing gels. If immune complexes form during this incubation, specific antibody bands are eliminated from the autoradiograph, as these complexes appear to be too large to enter the gel. abs, absorption with anti-idiotype; C, the mixture with normal guinea pig serum. Left two lanes are from B10.A mouse 1; right two lanes are from B10.A mouse 3.

the spleens of B10 mice injected intraperitoneally with HEL emulsified in Freund's complete adjuvant (CFA). Helper cells are demonstrable in the spleens of similarly immunised congeneic B10.A mice[7]. We have also established that a disulphide-containing peptide derived from this multi-determinant antigen (N–C peptide = 1–17: Cys 6–Cys 127:120–129) is equally capable of inducing these suppressor cells while another peptide from HEL (L_{II} peptide = 13–105) induces helper T cells in B10 mice[8]. To further characterise T-cell receptors in this system we have examined the effect of anti-idiotype on HEL-induced suppressor cells from non-responding B10 mice and HEL-induced helper cells from responding B10.A mice.

To investigate the lysozyme T-cell idiotypic repertoire in B10.A and B10 mice, anti-idiotypic antisera were generated against restricted anti-HEL antibody populations, which are often found in B10.A mice. Figure 1*a* shows the isoelectric focusing patterns (IEF) of antibodies from immune ascitic fluid of three B10.A mice after immunisation with HEL. These patterns are more restricted than those produced by similarly immunised A/J mice.

Two lysozyme-derived peptides, N–C and L_{II}, were used to investigate the specificity of these anti-HEL antibodies. Figure 1*b* and *c* show the IEF patterns of the same fluids as in Fig. 1*a* stained with the N–C peptide and the L_{II} peptide, respectively. As can be seen, all the antibody in the ascitic fluid of the HEL-immunised B10.A mice appears to react with the N–C peptide but not with the L_{II} peptide. Experiments with N–C immunoadsorbents corroborate the N–C staining results (data not shown). The selected A/J fluid shows some L_{II} reactivity but it does not represent a large portion of the total antibody (~15%).

Purified antibody from the ascitic fluid of one B10.A mouse (1 of Fig. 1) was isolated by adsorption to and elution from an HEL immunoadsorbent. The isolated antibodies were used to immunise guinea pigs and the resulting antiserum repeatedly passed over normal B10.A Ig columns. Figure 1*d* shows that the absorbed serum reacts with all the antibody bands present in the immunising population as well as all other B10.A anti-HEL antisera. The addition of large amounts of normal Ig to absorption mixtures had no effect on the ability of the guinea pig anti-idiotype to absorb HEL-specific antibody bands (data not shown).

As idiotypic determinants are antigenic structures close to or including the antigen-binding site of the antibody molecule, anti-idiotypic antibodies may interfere with the interaction of idiotype with antigen. Figure 2 demonstrates that the anti-idiotypic serum can inhibit the binding of B10.A anti-HEL to radiolabelled HEL by as much as 80%. The same anti-idiotype has no effect on the binding of B10.A anti-human lysozyme (HUL) antibodies to radiolabelled HUL. This inhibition of HEL binding is consistent with recognition of determinants associated with, or near, the antigen-binding site by the anti-idiotypic serum.

This anti-idiotype reacts with almost all anti-HEL antibodies we have examined regardless of the mouse strain from which they were derived. When L_{II}-specific antibodies occur, they lack the idiotype; in particular the L_{II}-reactive antibody in the fluid from A/J C3 shown in Fig. 1 is the only portion of that response which does not react with the anti-idiotype. Thus, this anti-idiotype appears to react with N–C-specific antibodies.

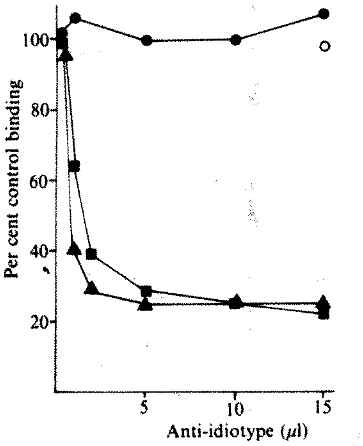

Fig. 2 Inhibition of B10.A anti-HEL binding to ^{125}I-HEL by anti-idiotype. Inhibition curves obtained when increasing amounts of anti-idiotypic antiserum were used to inhibit the binding of B10.A anti-HEL to ^{125}I-HEL or B10.A anti-HUL to ^{125}I-HUL. Increasing amounts of anti-idiotypic antiserum were added to tubes containing a suitable dilution of anti-HEL ascitic fluid. This dilution was capable of binding 49–55% of 10 ng of ^{125}I-HEL, or 10 ng of ^{125}I-HUL. Following appropriate incubation all the γ-globulin in each tube was precipitated by adding an equal volume of 36% (w/v) Na_2SO_4. After 2 h incubation at room temperature, the precipitates were collected by centrifugation, washed twice and counted in a Nuclear Chicago γ-counter. Data are presented as the per cent of control binding (that is, binding obtained in reaction mixtures without inhibitor). ■, B10.A mouse 1 anti-HEL; ▲, B10.A mouse 3 anti-HEL; ●, a single B10.A anti-HUL serum binding to ^{125}I-HUL. ○, Inhibition of B10.A mouse 1 anti-HEL binding to ^{125}I-HEL by 15 µl normal guinea pig serum.

This anti-idiotypic serum was used to examine the expression of idiotypic determinants on functional T-cell subpopulations. Results in Table 1 demonstrate that preimmunisation of B10 mice with HEL generates a cell population capable of suppressing the anti-HEL plaque-forming cell (PFC) response of primary spleen cell cultures stimulated *in vitro* with HEL–red blood cell (RBC). These suppressor cells have been shown to be sensitive to rabbit anti-mouse thymocyte or anti-I-J treatment[7]. Furthermore, suppressive activity is found in the cell population remaining after passage through nylon wool (B. Araneo, personal communication). Sequential treatment of HEL-primed spleen cells with anti-idiotype and complement eliminates the ability of these cells to suppress the anti-HEL PFC response, while treatment with normal guinea pig serum and complement does not affect suppression. If complement is omitted and the cells are only incubated with anti-idiotype for 30 min at 4 °C, attempting to block suppressive activity, almost no effect is observed. These results indicate that the suppressor T cells raised against HEL express some or all of this set of idiotypic determinants.

Using the same approach we tried to determine if these idiotypes were expressed on helper T cells. Results shown in Table 2 demonstrate that the helper activity induced in B10.A mice by HEL priming is not affected by treatment of HEL-primed spleen cells with anti-idiotype and complement, while in the same experiment, HEL-induced suppressor cells in B10 mice are sensitive to this treatment. Even when sodium azide (10^{-2} M) was added to stabilise membrane receptors, the helper activity was unaffected. This insensitivity may reflect a lower density or different arrangement of receptors on helper cells, or perhaps a rapid shedding of receptor from these cells.

Some preliminary evidence suggests that the helper cells being measured in the present assay are directed against a different determinant on HEL than are the suppressor T cells or B cells. This would be expected to lead to different idiotypy for the helper cells. In some other systems, helper cells can bear idiotypes identical to the dominant B-cell idiotype. Interestingly, this occurs where the antigenic element is multivalent, such as with streptococcal carbohydrates[9] or phosphorylcholine[10], where helper T cells specific for the repeating determinant can present the same antigenic determinant to B cells. In our system, this type of relationship is obviated because HEL is monovalent for any given epitope. The clear requirement for helper T cells of different specificity from that of the B cell could quite naturally lead to a functional helper population lacking the dominant idiotype.

Table 2 Anti-idiotype and complement treatment eliminates the activity of HEL-induced suppressor cells from B10 mice but not the activity of HEL-induced helper cells from B10.A mice*

Spleen cells (×10^6) per culture from mice primed with:		Treatment of HEL-primed spleen cells	Direct PFC per culture on day 4

* Immunisations, *in vitro* cultures, and antisera treatments as described in Table 1. HEL–human RBC were substituted for HEL–SRBC as antigen *in vitro*.

† Primary anti-HEL PFC responses obtained with normal B10.A spleen cells are routinely much lower than those obtained with normal B10 spleen cells.

Thus, the antibody specificity in the secondary response to lysozyme, a multi-determinant antigen, is restricted. Likewise, suppressor cells raised in the non-responder mouse show a remarkably similar restriction to this same determinant. We consider it no accident that receptors on each of these two cell populations should bear the same idiotypic determinants. This arrangement ensures that there will be mediation between suppressor T cells and B cells by helper T cells with complementary idiotypic or epitypic receptors. We are now studying the rules of antigenic and idiotypic circuitry which are involved in the selection of particular B cells for activation.

Immunoreactive forms of human erythrocyte ankyrin are present in diverse cells and tissues

Vann Bennett

Department of Molecular Biology, Wellcome Research Laboratories, Research Triangle Park, North Carolina 27709

Ankyrin is a polypeptide of molecular weight (MW) 200,000 which is tightly bound to the cytoplasmic surface of the human erythrocyte membrane and has been identified as the high-affinity membrane attachment protein for spectrin[1-3]. This protein has also been shown to be associated with band 3 (ref. 4), the major transmembrane protein in erythrocytes. Ankyrin is thus an example of a polypeptide which links a cytoplasmic structural protein to an integral membrane protein. A water-soluble, 72,000-MW, proteolytic fragment of ankyrin has been purified which retains the ability to bind to spectrin, and competitively inhibits reassociation of spectrin with membranes[5]. Monospecific antibodies directed against this fragment have been prepared[1] and demonstrated to cross-react only with ankyrin among the erythrocyte membrane proteins[1,4]. The present study reports the use of these antibodies to develop a radioimmunoassay capable of detecting femtomolar quantities of ankyrin, and demonstrates the presence of small but significant amounts of immunoreactivity in a variety of types of cells and tissues.

Ankyrin itself is not suitable as a ligand for radioimmunoassay because it is very sensitive to proteolysis, and has hydrophobic properties which would make nonspecific binding a serious problem[1]. The 72,000-MW water-soluble fragment of ankyrin, however, was readily radioiodinated and exhibited low background radioactivity in assay conditions. Monospecific anti-fragment IgG bound ^{125}I-labelled fragment with both a high-affinity interaction ($K_D = 0.3$ nM) and a lower-affinity association ($K_D = 12$ nM); 75–80% of the ^{125}I-labelled fragment was immunoreactive.

Binding of ^{125}I-labelled fragment to low concentrations of monospecific antibody (0.2 nM) was blocked completely by 0.4 pmol of unlabelled fragment, and a significant inhibition occurred with as little as 2 fmol of fragment (Fig. 1). Binding assays were carried out in the presence of Triton X-100, which permitted analysis of membranes and whole cells without prior solubilisation. Human erythrocyte ghosts block binding of ^{125}I-labelled fragment completely above 500 ng of membrane protein, and by 50% at 20 ng of protein (Fig. 1).

To estimate the amount of ankyrin present in ghost membranes, it was necessary to control for the possibility that the protein in a native conformation might associate with antibody to a different degree from its association with the soluble fragment. Accordingly, SDS-denatured fragment and ghost membranes were assayed for inhibition of binding. SDS-treated fragment exhibited unchanged activity, whereas SDS-treated membranes were twofold less effective (Fig. 1). The SDS-treated ghosts contained the equivalent of 0.36 pmol or 26 ng of fragment per μg membrane protein, which agrees closely with the previous estimate that the fragment constitutes 2.4% of the membrane protein[5]. Ankyrin thus comprises 7.2% of the total protein, a value corresponding to about 120,000 molecules per erythrocyte using the data of Steck for erythrocyte membrane proteins[9]. (This value is based on the assumption that the 72,000-MW fragment of ankyrin does not contain antigenic determinants that are repeated in the remainder of the molecule.)

Radioimmunoassay provides quantitative information only when the ligand used as a standard and the material to be assayed bind to the antibody with the same affinity and the same extent of cross-reaction. However, useful qualitative comparisons of levels of immunoreactivity can be made in heterologous systems, although the actual amount of antigen will in most cases be underestimated. Peripheral human blood neutrophils, platelets and human cultured fibroblasts from foreskin or embryonic lung exhibited a significant amount of immunoreactivity (Fig. 2). ^{125}I-labelled fragment was displaced by 50% using 5×10^4 erythrocytes, 8×10^3 neutrophils, 2×10^6 platelets and 1.4×10^5 fibroblasts per assay. These numbers correspond to 6×10^5 copies of ankyrin per neutrophil, 3×10^3 per platelet and about 3×10^4 per fibroblast. The slopes of the inhibition curves of these cells are less than that of erythrocytes, indicating partial cross-reactivity and/or decreased affinity for the antibody. The values for molecules per cell are thus probably underestimates. The activity of these cells is unlikely to be due to proteolysis by lysosomal enzymes, as samples boiled in SDS still compete for binding. Furthermore, problems of nonspecific interference in the assay were minimised by the very small quantities of cells used.

It was important to determine whether immunoreactivity could be detected in various tissues. Due to difficulty in obtaining fresh human material, erythrocytes from other species were compared for cross-reactivity. Rat cells were about 10-fold less active than those of humans, but were 3–5-fold more reactive than cells of horses or rabbits. Membrane fractions from rat brain, liver, kidney, testes and isolated epidydimal fat cells all exhibited immunoreactivity, with 50% inhibition at 0.4 μg for rat erythrocytes, 5.7 μg for brain, 9.5 μg for testes and about 12.6 μg for liver, kidney and fat cells (Fig. 3). These values correspond to the presence of ankyrin at 0.5% of the total membrane protein in brain, 0.2% in liver, kidney and fat cells, and 0.3% in testes, assuming that rat and human erythrocytes

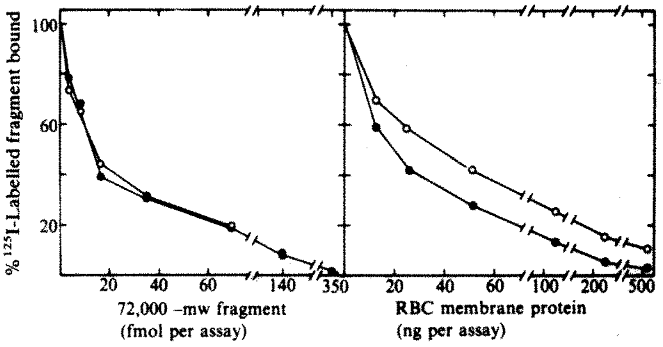

Fig. 1 Inhibition of binding of ^{125}I-labelled 72,000-MW fragment to monospecific anti-fragment IgG by unlabelled 72,000-MW fragment (left) and human erythrocyte membrane protein (right). Anti-fragment IgG (0.18 nM) was incubated for 1 h at 0 °C in 0.075 ml of buffer (100 mM NaCl, 10 mM sodium phosphate, *p*H 7.5, 1 mM EDTA, 250 μg ml^{-1} bovine serum albumin, 5 μg ml^{-1} pancreatic trypsin inhibitor, 0.2% (v/v) Triton X-100, 10 μg ml^{-1} preimmune IgG) in the presence of various concentrations of 72,000-MW fragment or erythrocyte ghost protein which were either untreated (●) or had been exposed to SDS (0.1%) (○). The final concentration of SDS was not more than 0.0025% at the highest dilution of these samples. ^{125}I-labelled fragment (prepared by the method of Hunter and Greenwood[6]; 3.6×10^6 c.p.m. pmol^{-1}, 0.4 nM final concentration) and 0.2 μl protein A-bearing staphylococci were then added as a second antibody[7], and the incubation was continued for another hour at 0 °C. The reaction was terminated by addition of 3.5 ml 2 M urea, 0.1 M glycine and 1% (v/v) Triton-X-100, and the bacteria, with adsorbed IgG, were collected by centrifugation (10 min, 3,000*g*), and analysed for ^{125}I. The data are presented as per cent of binding in the absence of additions, and are corrected for nonspecific binding by subtracting the value obtained with preimmune IgG alone at each concentration of fragment and membrane protein. Erythrocyte ghosts were prepared by hypotonic lysis in 7.5 mM sodium phosphate, *p*H 7.5 (ref. 8).

0028–0836/79/420597—03$01.00

contain the same amount of ankyrin and that the immunoreactive protein has the same molecular weight as ankyrin. Liver homogenates were fractionated by differential centrifugation into microsomal membranes which contained 55% of the immunoreactivity, a mitochondrial/lysosomal pellet which had 7% and a soluble fraction which had 30%. The soluble immunoreactivity may be due to proteolytic cleavage of the membrane-bound protein, for the 72,000-MW fragment of erythrocyte ankyrin is released frŏm the membrane with very limited proteolysis[5].

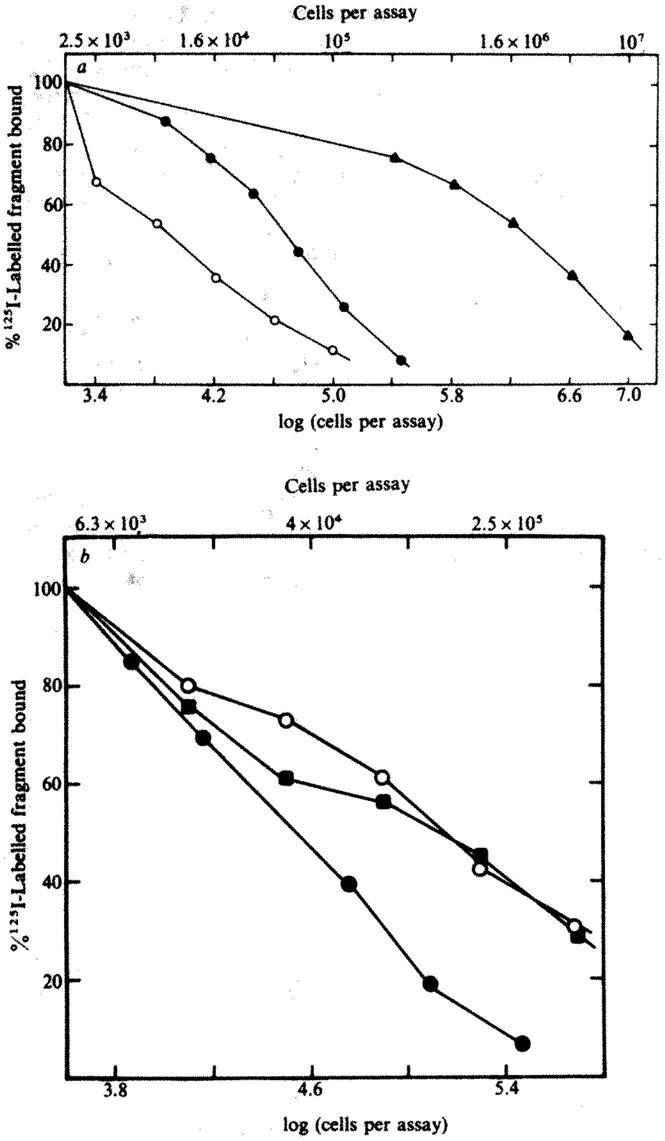

Fig. 2 Inhibition of binding of ^{125}I-labelled 72,000-MW fragment to monospecific anti-fragment IgG by human erythrocytes, neutrophils and platelets (a), and by cultured human foreskin fibroblasts and Wi-38 lung fibroblasts (*b*). Anti-fragment IgG (0.18 nM) was incubated as described in Fig. 1 in the presence of various amounts of human erythrocytes (●), neutrophils (○) and platelets (▲) (*a*), and, in a separate experiment, with human erythrocytes (●), cultured foreskin (■) and Wi-38 lung (○) fibroblasts. Binding of ^{125}I-labelled 72,000-MW fragment (3.6 × 10^6 c.p.m. pmol^{-1}, 0.6 nM) was then determined (Fig. 1). Peripheral blood cells were separated into erythrocytes, neutrophils and a combined lymphocyte and platelet fraction by the method of Boyum[10]. Lymphocytes and platelets were separated by sedimentation on sucrose gradients[11]. Cultured human fibroblasts from a foreskin explant and from embryonic lung (Wi-38) were grown to confluency in Eagle's minimum essential medium supplemented with 10% (v/v) fetal calf serum, and were detached after exposure to 150 mM NaCl and 5 mM Na EDTA, *p*H 7.5. The erythrocytes in these assays contain the equivalent of 100,000 ankyrin molecules per cell based on a radioimmunoassay with SDA-denatured cells and comparison with a standard curve of 72,000-MW fragment.

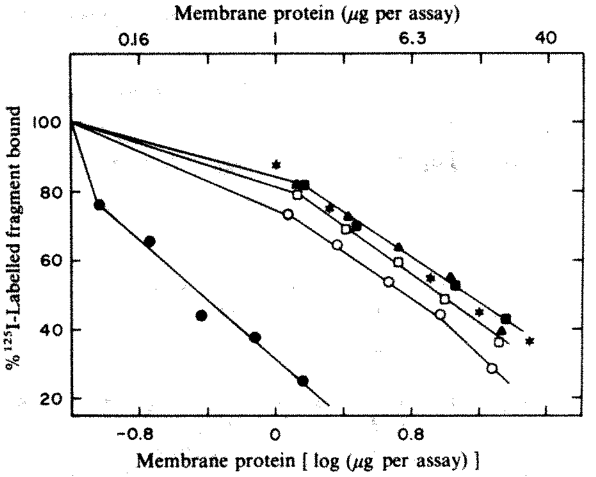

Fig. 3 Inhibition of binding of ^{125}I-labelled 72,000-MW fragment to monospecific anti-fragment IgG by membrane protein from rat erythrocyte ghosts, brain, liver, kidney, testes and epidydimal fat cells. Anti-fragment IgG (0.23 nM) was incubated in the presence of various concentrations of membrane protein from rat erythrocyte ghosts (●), brain (○), liver (■), kidney (▲), testes (□) and epidydimal fat cells (*), and binding of ^{125}I-labelled fragment (2 × 10^6 c.p.m. pmol^{-1}, 0.5 nM) was then determined (Fig. 1). Membrane fractions from rat tissues were prepared by homogenising 1 g of perfused liver or kidney, brain cerebrum, testes or isolated fat cells from eight 100-g rats[12] in 9 ml of 0.25 M sucrose, 2 mM Na EGTA, *p*H 7.0, and 200 μg ml^{-1} phenylmethylsulphonyl fluoride with a Brinkman polytron (30 s, 3,200 r.p.m.); the suspensions were pelleted for 10 min at 900*g* to remove nuclei, large particles and possible contaminating erythrocytes. The supernatants were then diluted 10-fold and centrifuged for 30 min at 250,000*g* to collect the membrane fractions.

The possibility of contamination of the membrane fractions from solid tissues by erythrocytes was minimised by using conditions for homogenising the tissues that lyse only 10–15% of erythrocytes, and including a low-speed centrifugation step to remove unbroken cells before isolation of the membranes. The amount of contamination by intact and lysed erythrocytes in these low-speed supernatants was estimated by solubilising membranes with Triton X-100, and measuring haemoglobin by absorbance at 578 nm. The values obtained by this assay corresponded to a maximum contamination of membranes with erythrocyte ankyrin of 0.005% for brain, 0.009% for liver, 0.008% for kidney and 0.006% for testes. The activity of these membrane fractions thus cannot be explained by contamination with erythrocyte membranes. Furthermore, fat cells have a density of less than 1 g cm^{-3}, and consequently float whereas other cells are sedimented. These buoyant cells are thus completely free of erythrocyte contamination, and still contain the same amount of immunoreactivity as liver and kidney.

The small amounts of immunoreactivity in these membrane fractions, and the extreme sensitivity of ankyrin to proteolysis, makes a detailed analysis of the cross-reacting polypeptides quite difficult. However, it was possible to immunoprecipitate with anti-ankyrin IgG a polypeptide of MW ~200,000 from ^{125}I-labelled brain and fat cell membranes (not shown). This polypeptide was not precipitated in the presence of excess, 72,000-MW ankyrin fragment, nor by preimmune IgG. Many other polypeptides were also present in the immunoprecipitates, but their precipitation was not reduced by the ankyrin fragment, and they were also obtained with preimmune IgG.

The molecular weight of erythrocyte ankyrin is similar to that of myosin and of filamin. These proteins, however, did not contribute to the cross-reactivity in these various cell types. as partially purified myosin or filamin from human platelets were not active in the radioimmunoassay. Furthermore, the total protein fraction from rat skeletal myofibrils exhibited very low activity.

These results demonstrate the ubiquitous presence of small amounts of an ankyrin-like protein distinct from myosin or filamin which is associated primarily with membrane components. Ankyrin links band 3 to the erythrocyte cytoskeleton[4], and may have a related function in specialised regions of the plasma membrane in other cells. Spectrin was not detected in cultured cells by radioimmunoassay[14], but this negative result could be explained by poor cross-reactivity of the antibody or by insufficient sensitivity of the assay. It is conceivable that proteins analogous to ankyrin, spectrin and band 3 could be present together in non-erythrocyte cells, and could be involved in processes requiring direct contact between integral membrane proteins and structural proteins on the inner surface of the membrane.

A mutation in *Caenorhabditis elegans* that increases recombination frequency more than threefold

A. M. Rose & D. L. Baillie

Department of Biological Sciences, Simon Fraser University, Burnaby, British Columbia, Canada

In higher organisms the rate of recombination between genetic loci is presumably responsive to selective pressure. Recently, selective pressures[1] and mutational events[2] that influence recombination have been reviewed. Mutational sites and chromosomal rearrangements that enhance or suppress recombination frequency in specific regions are known, but general mechanisms that enhance recombination have not yet been discovered. We describe here the isolation and characterisation of a strain of the hermaphroditic nematode, *Caenorhabditis elegans*, that has a recombination frequency at least threefold higher than that found in the wild type[3,4]. In this strain, *rec-1*, the number of reciprocal recombination events between linked loci is increased. This is true for all pairs of linked loci studied so far. The high recombination strain behaves as if it carries a classical, recessive mutation, although a second mutation exists which can alter the recessive behaviour of *rec-1*.

We established a strain heterozygous for mutations in closely linked loci on chromosome I. This strain, *dpy-5 unc-15+/++unc-13*, has a wild-type appearance. When allowed to self-cross it segregates dumpy paralysed (*dpy-5 unc-15/dpy-5 unc-15*), uncoordinated (*unc-13/unc-13*) and wild-type appearing (*dpy-5 unc-15+/++unc-13*) progeny. *dpy-5 unc-15/dpy-5 unc-15* are short, fat worms that cannot move, and *unc-13/unc-13* have a characteristic contorted appearance and movement. In addition to these phenotypes, recombinant dumpy (*dpy-5+/dpy-5 unc-15*) and paralysed (*+unc-*15*/dpy-5 unc-15*) progeny will occur. By selecting the hermaphrodites with wild-type appearance, this strain was maintained for several generations, and eventually scored for recombination between the *dpy-5* and *unc-15* loci. The frequency of recombination in this region was known from previous experiments[4] to be approximately 2% at 20 °C when all the progeny of a single parent were scored. In the heterozygous strain that we were maintaining, the recombination frequency between *dpy-5* and *unc-15* was approximately 7%. We hypothesised that our *unc-13/unc-13* strain, used to make the heterozygous strain, carried a factor responsible for this increase in recombination frequency. To demonstrate the existence of this factor, we out-crossed our uncoordinated strain to wild type and generated *unc-13/+* males. These males were crossed to *dpy-5 unc-15/dpy-5 unc-15*. On self-crossing, half the F_1 heterozygotes from this cross showed a high frequency of recombination among their progeny, while the other half had a normal recombination frequency. Successive generations of the high recombination individuals were measured for recombination frequency until a homozygous strain of high recombination hermaphrodites (XX) was established. This strain was treated at 26 °C for 30 h to produce males (X0) by X-chromosome nondisjunction. When these males were crossed to *dpy-5 unc-15/dpy-5 unc-15*, all the F_1 heterozygotes segregated a high number of recombinant individuals. After elimination of *dpy-5*, *unc-15* and *unc-13* mutant alleles by recombination, we established a male strain homozygous for *rec-1*, but having no visible mutant phenotype.

Table 1 The effect of *rec-1* on recombination frequency (%)

	Parental genotypes		
ab	*ab/++*	*ab/++; rec-1/+*	*ab/++; rec-1/rec-1*
dpy-5 unc-13 (I)	1.51±0.3*	1.30±0.3	12.41±1.6
dpy-14 unc-56 (I)	†	0.61±0.2	4.14±1.5
unc-22 unc-43 (IV)	1.90±0.6	1.55±0.4	3.95±1.4
dpy-11 unc-42 (V)	2.21±0.3	2.60±0.7	7.92±1.8

* ±95% confidence intervals.
† Not determined.

Table 2 The influence of *s155* on the expression of *rec-1*

	Parental genotypes	
ab	*ab/++; s155/+*	*ab/++; s155/+ rec-1/+*
	Recombination (%)	
dpy-5 unc-13 (I)	1.15±0.3	7.34±0.9
dpy-5 unc-15 (I)	1.80±0.4	9.11±0.9
dpy-5 dpy-14 (I)	1.62±0.6	5.50±0.9

Males from this strain were crossed to *dpy-5 unc-13/dpy-5 unc-13* individuals. Unlike before, all the F_1 heterozygotes produced a normal number of recombinants among their progeny. In the F_2, two types of heterozygote occurred—those which gave a normal frequency of recombinants and those which gave a high frequency of recombinants. Approximately one-quarter of the F_2 heterozygotes had high recombination frequencies and produced true-breeding high recombination progeny. In a parallel control experiment, *dpy-5 unc-13/dpy-5 unc-13* were crossed to *+/+* males and scored for recombination frequency in the F_1, F_2 and F_3. In this case the recombination frequency remained approximately 2% in every generation. From these studies, we concluded that the *rec-1* strain has a segregating factor which assorts independently of chromosome I. This factor is responsible for at least a threefold elevation in recombination frequency.

To investigate the generality of this increased recombination phenomenon, *rec-1/rec-1* males were crossed to other pairs of linked loci on chromosomes I, IV and V. The results showed that *rec-1* acts recessively to increase recombination frequency between two pairs of linked loci on chromosome I (Table 1). On

0028-0836/79/420599—02$01.00

chromosomes IV and V, recombination frequency in the *unc-22 unc-43* and the *dpy-11 unc-42* regions, respectively, was measured. Here also, an increase in recombination frequency was observed (Table 1). We interpret these results as evidence that *rec-1* is a general enhancer of recombination frequency in *C. elegans.*

With certain pairs of linked loci, a high recombination frequency was observed in the F_1 generation. For example, when *rec-1* males were crossed to *dpy-5 unc-15/dpy-5 unc-15* or *dpy-5 dpy-14/dpy-5 dpy-14*, the F_1 heterozygotes had a higher recombination frequency than wild type. From these results we hypothesised that *dpy-5 unc-15/++* and *dpy-5 dpy-14/++* individuals carry a site, *s155*, responsible for the dominant behaviour of the high recombination factor.

A strain, homozygous for *dpy-5 unc-13* and *s155* was constructed. If *s155* is, in fact, responsible for conferring dominant behaviour on *rec-1*, then *s155*-carrying *dpy-5 unc-13/dpy-5 unc-13* individuals should behave differently from *dpy-5 unc-13/dpy-5 unc-13* individuals when crossed to *rec-1*. Table 2 shows that when pairs of loci on chromosome I are tested in the presence of *s155*, *rec-1* acts dominantly. This provides evidence that a second mutation can modify the recessive nature of *rec-1*. Experiments are in progress to test whether *s155* can confer dominance on regions on other chromosomes.

We believe this to be the first demonstration of a general enhancer of recombination frequency in a higher eukaryote. The existence of a gene that can alter recombination and that is susceptible to mutation provides a mechanism whereby recombination frequency can be selected. It may be possible that, in addition to this allele of *rec-1*, other alleles which decrease recombination frequency can be recovered. If so, perhaps different levels of recombination frequency are selected in exclusively self-crossing or exclusively out-crossing populations. Furthermore, our *rec-1* strain may have an elevated spontaneous mutation rate. Three new visible phenotypes independent of *rec-1* have been observed in this strain. Thus, it is possible that the mechanism by which *rec-1* acts also alters the mutation frequency. This and other questions regarding the mode of action of *rec-1* are being investigated.

Correlation between fragmented immunoglobulin genes and heavy chain deletion mutants

Blas Frangione* & Edward C. Franklin

Irvington House Institute, Departments of Pathology* and Medicine, New York University Medical Center, 550 First Avenue, New York, New York, 10016

It is generally accepted that the variable (V) and constant (C) regions of immunoglobulin (Ig) chains are under separate genetic control[1]. The notion that the different domains and interdomain regions are also under the control of independent genetic units was initially based on the clearcut results obtained by studying the primary structure of deletion mutants[2-9] and received definitive support from direct analysis of cloned heavy (H) and light (L) chain genes[10-13]. Here we present additional studies carried out on two selected γ3 deletion mutants which indicate that the genetic control of human H chains may be even more complex than previously believed.

L and H chains of Ig molecules consist of two functionally differentiated segments: the amino-terminal V region which contains the antigen binding sites, and the carboxy-terminal C region[14]. Sequence and crystallographic studies have shown that the C region of the IgG H chain is composed of three domains: CH1, CH2 and CH3. The striking structural homology among the C region domains, each of which is composed of about 110 residues folded into an almost identical tertiary structure, and the lesser homology to the V regions suggest a common evolutionary origin by a series of gene duplications. Each domain has a well defined function. The CH1 domain contains the attachment point for the L chain and pairs with the CL domain; together with paired VH and VL domains containing the antigen binding sites they form the Fab fragments of the IgG molecules. The CH2 domains, which act in complement fixation, and the CH3 domains, which are involved in cell surface interactions together form the Fc fragment. In the middle of the H chains of all subclasses of IgG, there is a region of 15–62 residues of unknown origin and function called the hinge region or Fh fragment, which separates the Fab and Fc fragments[15,16]. Thus, the γ H chain is composed of five discrete structural and functional units.

Heavy chain disease (HCD) protein SPA is an 80,000-molecular weight (MW) dimeric γ3 human H chain mutant with a blocked amino terminus. The amino-terminal sequence after unblocking is: $<\overset{1}{\text{Glu}}$-Glu-Glu-Val-Arg-Glu-Ser-$\overset{8}{\text{Glu}}$-Leu-Lys-Thr-Pro-Leu-Gly-Asp-Thr-Thr-(His)-Thr-Cys-Pro-(Pro)-Cys-Pro. Comparison with the prototype VH amino-terminal sequences shows that although the first seven residues bear some resemblance to the normal amino terminus they do not correspond to any known VH subgroup or CH1 sequence[25]. Position 8 is the beginning of the normal γ3 hinge region[16]. On the basis of its amino acid analysis and high cysteine content it seems

IVS II, III, VII and VIII are present in the cloned DNA fragment coding for the murine γ1 constant region[13], and IVS I–VII are suggested by the structure of γ3 deletion mutants and myeloma proteins with a deleted hinge[5,23,24]. ↓, Indicate splicing sites as defined by deletion mutants; ⇣, not observed in man. *b*(ii), Human γ3 heavy chain. . . . V domain; ▩, VC region; ■, hinge region (quadruplicated); ——, CH1, CH2, CH3: constant domains. *c*, γ3 deletion mutants. Heavy chain disease proteins WIS, SPA, CHI[7] and ZUC[2,17]. For a complete list of deleted H chains see refs 6 and 9 for mouse and human, respectively.

likely that the intact hinge and the entire Fc fragment are present and that protein SPA has an internal deletion of about 210 residues comprising most of the V, the VC or J (junction) and CH1 regions.

HCD protein WIS is an 86,000-MW protein composed of two identical 289-residue chains. Figure 1 shows its amino acid sequence (details will be published elsewhere). It has two carbohydrate moieties attached to Asn 6 and Asn 140 and position 7 contains an unusual cysteine residue. Homology of the first 11 residues to both VH and the VC junction region has been previously pointed out[8]. The size of the deletion is about the same as that of protein SPA as position 12 marks the beginning of a normal hinge, consisting of 62 residues composed of 4 homologous regions. The hinge starts with a 17-residue segment (residues 12–28) followed by a 15-residue segment which is identically and consecutively repeated three times (residues 29–43, 44–58 and 59–73). The sequence from residue 74 to the carboxy terminus seems to be similar to that of previously reported Fc fragments[17].

The unexpectedly high frequency of deletion mutants belonging to the γ3 subclass allows conclusions of general significance. Figure 2*c* compares protein WIS and SPA with two other previously reported γ3 deletion mutants, protein CHI (ref. 7) and ZUC (refs 2, 17). The most constant feature of γ-chain deletion mutants is the presence of an internal deletion involving part of the VH and usually all of the CH1 domains which usually ends at the hinge. In the case of γ3 mutants, the deletion can end either at the beginning of quadruplicated hinge, or in one case (ZUC), at the beginning of one of the segments. In contrast, in different γ heavy chain deletion mutants the amino terminus can be normal—similar but not identical to—the known VH subclasses, as is the case in the proteins reported here, or very different from the usual amino terminus[3]. This complexity precludes any generalisations as to possible mechanisms responsible for these findings and has been discussed previously[18]. The constancy of the remainder of the Fc fragment as reflected by the relatively infrequent occurrence of additional mutations in CH2 and CH3 domains has also been emphasised before and is further supported by the sequence of protein WIS.

The unique structure of the hinge contrasts with the striking homologies of the four H chain domains. Its basic subunit is 15 residues long, rich in proline and contains the inter-heavy chain disulphide bridges and sometimes the HL bridge[15]. Its origin is unknown; it could be part of a gene coding for a domain which has undergone deletions and mutations, it could be encoded by intervening sequences shown to be present between genes coding for domains[13], or as previously suggested it may be an inserted DNA fragment (transposon) capable of joining duplicated genes which have evolved to perform different biological functions[4], somewhat analogous to the J fragment of the L chain[11]. These features, together with the finding that the hinge often marks the end of the internal deletions[9], that it can be deleted selectively[5,9], and that it is a site where duplications and unequal crossing over occur[16], have given rise to the suggestion that the hinge may be under the control of a separate genetic unit. This possibility has received strong support from the recent observation that non-coding DNA segments occur not only between the domains but also at each side of the hinge in the case of cloned DNA for murine γ-chains[13] (Fig. 2*a*).

Eukaryotic genes, including immunoglobulin L and H chain genes, are organised into transcriptional units in which coding segments of DNA (exons) alternate with non-coding sequences (intervening sequences or introns) to be excised from the primary transcript[10–13,19]. The organisation of the immunoglobulin genes seems to be unique in that the intervening sequences apparently separate exons coding for structural subunits or domains. In the case of the cloned DNA coding for the constant region of the mouse γ1 heavy chain, electron microscopy and sequence analysis revealed four exons separated by four intervening sequences[13] (Fig. 2*a*). Comparison with the known amino acid sequence[20] demonstrated that the exons represent the three CH domains and the hinge, and that no other intervening sequences exist within coding DNA segments. However, because of the complexity of human γ3 hinge gene(s), additional intervening sequences and splicing sites can be anticipated between the subunits of its quadruplicated hinge region (Fig. 2*b*, H region). In addition, based on the unusual V region sequences in γ deletion mutants and the sequence of protein WIS (see Fig. 1, residues 8–11), intervening sequences similar to those described for the mouse λ-chain gene[10,11] (Fig. 2*b*) may also exist near the amino terminus of the V gene and at the J region. Because the intervening sequences are excised from the precursor and the coding regions rejoined, there must be some recognition signal at the junction between the intervening and the coding sequences to permit the accurate excision and splicing necessary to produce the mature mRNA[21]. Such seems to be the case for the repetitive subunits of the hinge genes which, as pointed out before, have kept sequence signals similar to those at the joining sites between VJ and C genes of the L chains[22].

In both H and L chain deletion mutants there is a striking correlation between the borders of deletions and the recently defined points of splicing. Figure 2 correlates the splicing points defined for mouse γ1 constant genes with sites previously described for recombination in deleted H chains. There is also similar striking correspondence for fragmented L chain genes and two L chain mutants[8] which end at the intervening sequences bordering the J region. If sites of splicing determine where deletions can end, as seems to be the case in all mutants studied so far, the finding that in protein ZUC the deletion ends at the last subunit rather than the beginning of the quadruplicated hinge provides additional support for the existence of splicing points and intervening sequences between the subunits of the hinge (Fig. 2*b*).

Although the mechanisms responsible for the deletions are not known, the defect could occur either at the DNA level or during splicing events when heterogeneous nuclear RNA is converted to mature mRNA. A mutation at or near a splicing site could alter the splicing pattern so that the entire coding region can be skipped in the mRNA; alternatively, if the splicing enzyme(s) can bridge non-adjacent encoded regions, large deletions involving more than one genetic unit could result in mutant proteins in which more than a single domain can be eliminated. Studies of immunoglobulin variants, together with DNA cloning of selected mutant cells, will undoubtedly continue to provide clues to the genetic mechanisms involved in H and L chain control and pose interesting questions about the evolution and significance of eukaryotic fragmented genes.

This work was supported by USPHS research grants AM 01431 and AM 02594 and the Irvington House Institute. We thank Dr G. Selbowitz for protein WIS and Dr J. A. Morales for protein SPA.

Suppression of the nonsense mutation in homozygous β^0 thalassaemia

Judy C. Chang, Gary F. Temple, Richard F. Trecartin & Yuet Wai Kan

Howard Hughes Medical Institute Laboratory and Hematology Service,
San Francisco General Hospital, University of California,
San Francisco, California 94143

The common form of β thalassaemia associated with elevated haemoglobin A_2 levels can be broadly classified as β^+ or β^0 type according to the presence or absence of β-globin chain synthesis in the homozygous state[1–4]. The molecular pathology of each type is heterogeneous[3–9]. Apart from a subgroup of Indo-Pakistani patients[10], the β-globin structural gene is intact in the majority of patients with β^0 thalassaemia[2–4]. The amount of β-globin mRNA present in the reticulocytes of these patients varies[5–7]: in some it is absent or barely detectable; in others, a substantial amount is present, but it is nonfunctional. We recently demonstrated that the molecular lesion in a Chinese patient with nonfunctional β-globin mRNA[11,12] was due to the mutation of the normal lysine codon AAG at amino acid 17 to the amber terminator codon UAG, which prematurely terminates the β-globin chain[13]. In the present study we demonstrate the first example of a nonsense mutation in humans which can be suppressed *in vitro* by the suppressor tRNA, as has been found in other eukaryotic cells and viruses[14,15].

The *in vitro* translation of the globin mRNAs prepared from the reticulocytes of the patient with homozygous β^0 thalassaemia was performed in the micrococcal nuclease-treated rabbit reticulocyte lysate system using ^{35}S-methionine as the radioactive amino acid[16]. The globin chains synthesised were separated on a carboxymethyl cellulose column[17] (Fig. 1). The patient's mRNAs directed the synthesis of α- and γ-globin chains but no β-globin chain in the rabbit reticulocyte system. When a serine-inserting amber suppressor tRNA which recognises the codon UAG was added to the mRNA in the cell-free system a new radioactive peak appeared. Its radioactivity was about one-twentieth of that of α-globin. This new polypeptide chain eluted from the column earlier than the β^A-globin marker, consistent with the insertion of serine instead of lysine in amino acid number 17 by the serine suppressor tRNA. We did not detect any additional peaks as the normal termination codons of α-(UAA) (ref. 18) and γ-globin (UGA) (ref. 19) would not be suppressed by this tRNA. As a control, we added this suppressor tRNA to the mRNA from a patient with sickle cell anaemia and detected no new radioactive peak (data not shown).

To confirm that the newly synthesised polypeptide from the β^0 thalassaemia mRNA was a β-globin chain, we digested the polypeptide with trypsin, separated the tryptic peptides by high voltage paper electrophoresis[20], and identified the ^{35}S-methionine-containing peptide, βT5 (amino acid numbers 41–59). The βT5, from the newly synthesised chain, migrated to the same position as that of the β^S chain, confirming that it was indeed a β-globin chain (Fig. 2).

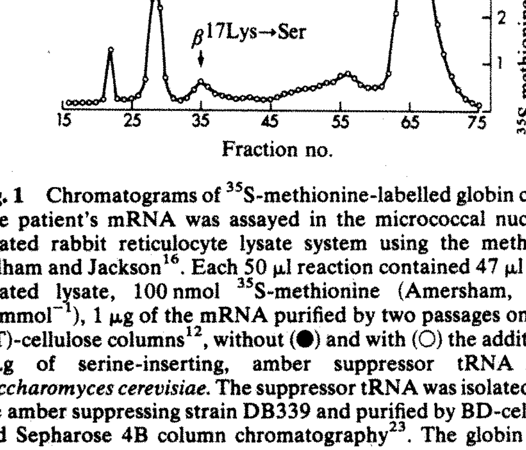

Fig. 1 Chromatograms of ^{35}S-methionine-labelled globin chains. The patient's mRNA was assayed in the micrococcal nuclease-treated rabbit reticulocyte lysate system using the method of Pelham and Jackson[16]. Each 50 µl reaction contained 47 µl of the treated lysate, 100 nmol ^{35}S-methionine (Amersham, 1,000 Ci mmol^{-1}), 1 µg of the mRNA purified by two passages on oligo (dT)-cellulose columns[12], without (●) and with (○) the addition of 6 µg of serine-inserting, amber suppressor tRNA from *Saccharomyces cerevisiae*. The suppressor tRNA was isolated from the amber suppressing strain DB339 and purified by BD-cellulose and Sepharose 4B column chromatography[23]. The globin chain products were separated on a carboxymethylcellulose column as previously described[17]. The position of elution of normal γ-, β^A- and α-globin chains was determined by optical density measurements of 5 mg of HbA and F added as carrier.

0028–0836/79/420602—02$01.00

The amount of β-globin mRNA present in this patient's reticulocytes was 15% of the α-globin mRNA[4]. Since the efficiency of the suppressor is generally not more than 60% (refs 21, 22), the amount of β-relative to α-globin synthesis would be about 10%. The finding of a $\beta:\alpha$ ^{35}S-methionine radioactivity ratio of 1:20 is consistent with this since β-globin chain contains one, and the α-globin two methionine residues. The low level of β-globin mRNA may be due to premature degradation of the mRNA, as a result of lack of ribosomes over nearly 90% of the coding region following the nonsense mutation. Such a mRNA would be more susceptible than normal to nuclease degradation within the erythroid cell. In addition, the decreased β-globin mRNA could also be partially explained if one of this patient's β-globin alleles contained the nonsense mutation while the other contained a different kind of mutation which results in the absence of mature β-globin mRNA from that gene.

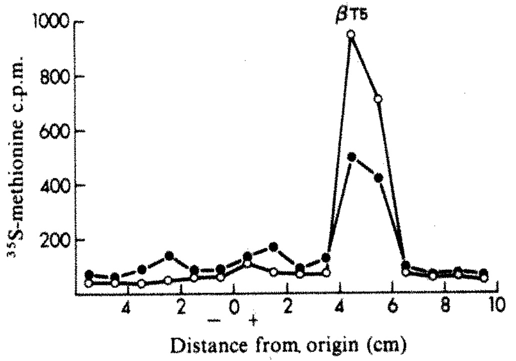

Fig. 2 High voltage electrophoresis of ^{35}S-methionine-labelled tryptic peptides. The β-globin peaks from cell-free synthesis products with mRNA from the β^0 thalassemic patient (●) and a patient with sickle cell anaemia (○) were desalted through a Sephadex G-25 column in 0.5% formic acid, and lyophilised. 200 μg of globin from each peak was incubated in 0.5 ml of 1% NH_4HCO_3 at 37° C with 8 μg of trypsin (Worthington TPCK-treated, 259 units mg^{-1} for 4 h. The hydrolysate was twice lyophilised and dissolved in 10 μl of pyridine acetate buffer (pyridine: acetic acid: water 25:0.3:75 by volume), *p*H 6.58. The peptides were separated by electrophoresis on 3 MM paper at 2,000 V for 2 h, 1-cm strips of the paper were cut out and the radioactivity measured in a Beckman liquid scintillation counter.

This study corroborates our sequence analysis data on this patient which indicated that β^0 thalassaemia is the result of a nonsense mutation within the β-globin structural gene[13]. To date, only one likely example of a nonsense mutation in higher eukaryotic cells has been reported. Capecchi *et al.* described a mouse cell line deficient in the enzyme hypoxanthine guanine phosphoribosyl transferase (HGPRT)[14]. The mutant enzyme was probably shortened at the carboxy terminus. Fusion of the defective cells with erythrocytes preloaded with either *Escherichia coli* or yeast suppressor tRNAs restored HGPRT activity when the erythrocytes contained ochre (UAA) but not amber (UAG) suppressor tRNA. Our results indicate that a defined nonsense mutation in human β-globin mRNA can be suppressed *in vitro* using the appropriate yeast suppressor tRNA. Similarly, delivery of suppressor tRNA to the erythroid cell precursor of patients with β^0 thalassaemia due to nonsense mutations may correct the β-globin defect. This approach may offer new methods for treatment of this disorder.

It is likely that nonsense mutations may have occurred at different locations along the β-globin mRNA in other β^0 thalassaemias. The use of suppressor tRNAs will facilitate the detection of nonsense mutations in the various thalassaemia syndromes as well as in other genetic disorders where a specific protein is deficient or absent.

We thank Drs Ray Gesteland and Norma Wells for suppressor tRNA. This work was supported by grants from the NIH and the National Foundation–March of Dimes.

Heterozygosity of *H–2* loci in wild mice

William R. Duncan

Department of Cell Biology, The University of Texas Health Science Center, 5323 Harry Hines Blvd, Dallas, Texas 75235

Edward K. Wakeland & Jan Klein

Abteilung Immungenetik, Max-Planck-Institut für Biologie, Corrensstr. 42, 7400 Tübingen, FRG

The major histocompatibility complex (MHC) is a cluster of genetic loci coding for cell surface molecules that seem to be the second most important element of the vertebrate immune system after immunoglobulins[1]. The MHC loci can be divided into three classes. Class I loci code for molecules of about 44,000 molecular weight (MW) which seem to function as markers of self in T-lymphocyte-mediated cytotoxicity. Class II loci code for molecules consisting of two polypeptide chains, of MW 34,000 and 28,000 respectively, which are believed to regulate the immune response by controlling the behaviour of helper and suppressor T lymphocytes. Each molecule may carry several antigens—one 'private' (characteristic for the allele controlling this molecule) and several 'public' ones[2] (shared with molecules controlled by other alleles). Class III loci code for serum proteins. One of the most characteristic and remarkable properties of the MHC loci, in particular class I, is their genetic polymorphism, defined as the existence in a population of two or more alleles at appreciable frequencies[3–5]. In *H-2*, the MHC of the mouse, individual alleles at class I *K* and *D* loci occur in the two populations that have been studied thus far with an average frequency of about 2% (ref. 5). We estimate, therefore, that these two populations contain some 100 alleles at each of the two loci. The polymorphism of class II locus *A* seems to be somewhat lower than that of the class I loci (average allelic frequency of 2–5%), while at the second class II locus (*E*) only five alleles have been identified[5]. The polymorphism implies that a high degree of heterozygosity should exist at the MHC loci in natural populations, and this has been found at the *HLA* loci, the human MHC (for review see ref. 6). We report here a similarly high frequency of heterozygosity in the mouse *H-2* complex in a population of mice, in spite of a social structure that would tend to reduce heterozygosity.

Table 1 Class I H-2 antigens of wild mice and their progeny

Wild males were mated with MWT ($H\text{-}2^b$) females and tested, together with their progeny, in the cytotoxic test against a panel of operationally monospecific antisera. Positive reactions for private and semiprivate antigens listed under Phenotype were found.

There are two ways of estimating *H-2* heterozygosity. First, if all private H-2 antigens and the loci coding for them in a given wild mouse sample were known, one could determine the heterozygosity of each locus simply by counting individuals carrying two allelically determined private antigens. Because, however, we do not know all the private H-2 antigens and we often do not know the identity of loci (*H-2K* versus *H-2D*) controlling them, we can only use this method to estimate the minimal frequency of *H-2* heterozygotes. As there are two major class I and two major class II loci, the presence of three private class I or class II antigens in an individual must mean that this individual is heterozygous in at least one class I (or class II) locus. Similarly, simultaneous presence of four private class I or class II antigens in an individual can be interpreted to mean that this individual is heterozygous at the two class I or class II loci. Individuals with two or less private antigens may or may not be heterozygotes, and it is this uncertainty that makes the estimate minimal.

Wild mice were captured at 15 different localities in Texas, and typed in the dye-exclusion cytotoxic test with 49 H-2 antisera and 12 Ia sera, which detected 36 private class I and 10 class II antigens[5]. In this sample of 88 mice, 31 mice carried more than two private class I antigens (data not shown). Thus, the minimal frequency of *H-2* heterozygotes at class I loci among Texas mice is 35%.

The second way of estimating *H-2* heterozygosity involves crossing wild males (wild female mice do not usually mate in captivity) with an *H-2* homozygous testing stock of laboratory mice, and *H-2*-typing the progeny of this cross. Segregation of private H-2 antigens among the progeny indicates heterozygosity of the wild father. This method fails only in cases where the father does not carry any known private antigens or where one of the paternal *H-2* chromosomes carries a strong segregation distorter, such as that present in the *H-2* linked *t* complex[7].

This second approach was applied to 26 of the mice captured in Texas, which were mated with $H\text{-}2^b$ homozygous MWT stock. From these matings 90 hybrids and their fathers were obtained and typed with the above panel of H-2 and Ia antisera (Table 1). Two of the 26 wild males (and their progeny) did not carry any of the private class I antigens detected with our battery of antisera. Of the remaining 24 males, private H-2 antigens segregated in the progeny of 23; the offspring (six) of only one mouse (DF 88) all carried the same class I antigens as their father. Provided that this result was not caused by segregation distortion, this one mouse might have been an *H-2* homozygote. Thus, the overall frequency of class I heterozygotes in the sample was 96%. In seven of the wild fathers private antigens were present that are known to be controlled by the *H-2K* locus. All seven mice proved to be heterozygous at this locus. Similarly, in four mice, antigens known to be controlled by the *H-2D* locus were found, and these mice were also all *H-2D* heterozygotes. With regard to class II antigens, it was possible to type 10 mice for Ia-1 and 19 mice for Ia-5 antigens. Eight of the Ia-1 and nine of the Ia-5 mice were heterozygous. Hence, the frequency of heterozygotes at *Ia-1* and *Ia-5* loci is 80 and 47%, respectively (Table 2).

This high degree of heterozygosity is unprecedented in a wild mouse population. The average frequency of heterozygotes at all other polymorphic loci tested is about 6%, with the highest recorded frequency of 28.6% for malic enzyme[8]. The *H-2* far exceeds this frequency. In fact, in the *H-2* system, maximum heterozygosity is achieved in that, at least for the class I loci, virtually all the mice are heterozygous.

Table 2 Number of wild mice heterozygous at individual *H-2* loci

Locus	Heterozygous total tested	% Heterozygotes
H-2K	7/7	100
H-2D	4/4	100
Class I*	23/24	96
Ia-1	8/10	80
Ia-5	9/19	47
All *H-2*†	25/26	96

*Includes mice in which *H-2K* and *H-2D* loci could not be distinguished phenotypically.

† If one of the four loci tested was heterozygous, the mouse was counted as a heterozygote.

How does this high *H-2* heterozygosity of natural mouse populations arise? Were the mouse population of the random mating type, such a high frequency of *H-2* heterozyotes would be expected. If the frequency of individual *H-2* alleles is—as preliminary data[5] suggest—about 2%, and if there are approximately 100 alleles at each of the three highly polymorphic *H-2* loci (*H-2K*, *H-2D* and *Ia-1*), then the expected frequency of *H-2* heterozygotes would be nearly 100%. However, it is known that mouse populations are not of the random mating type. On the contrary, they are broken down into family units or demes, each family consisting of one dominant male, a few subordinate males and a few females (for review see ref. 9). The demes are more or less closed, with little evidence for interdemic migration. Although there is almost no evidence indicating that mice in Texas live in deme-type populations, there is no reason to believe that they are different in this respect from mice in other geographical areas. Furthermore, preliminary data on mice from Germany indicate that these too display a high degree of *H-2* heterozygosity (unpublished). Thus, the phenomenon seems to be of general validity.

The deme structure of the mouse population and the high degree of heterozygosity need to be reconciled. There is considerable evidence indicating that mice within a deme (or locality) genetically resemble one another more than mice of different demes (see ref. 9). This observation, which also applies to minor histocompatibility loci[10] (that is, *H* loci that are not members of the MHC), suggests that a certain degree of inbreeding occurs within a deme. The intrademic inbreeding should lower the heterozygosity at the *H-2* loci, the degree of the decrease depending on the inbreeding coefficient. As the latter is not known for the population tested, we cannot estimate how large a decrease to expect. Should the value of the inbreeding coefficient in this population prove to be far from negligible, the fact that near 100% *H-2* heterozygosity occurs would mean that the effect of inbreeding is probably offset by heterozygous advantage at the *H-2* loci.

Evolutionary nucleotide replacements in DNA

Thomas H. Jukes & Jack Lester King

Department of Biology,
University of California, Santa Barbara, California 93106

With the increasing availability of analytical information on mRNA molecules, it is now possible to compare homologous nucleotide sequences from different organisms and to draw conclusions about their evolution. Such comparisons[1,2] have shown that silent changes in codons occur more frequently than nucleotide replacements that produce changes in amino acid sequences (code-altering changes). Furthermore, there is an important difference between amino acid sequence comparisons and nucleotide sequence comparisons. The former show only differences in amino acid residues, but the latter show several types of differences when corresponding codons are compared[3]. Single-base replacements may be degenerate (silent) or expressed as amino acid replacements. Two-base codon changes may be degenerate, single-base changes, or be visible as such. Three-base codon changes may be degenerate (involving serine), simulate either single-base or two-base changes or be visible as such. All nine types of change are found in comparisons of genes from the viruses ΦX174 and G4. The relative numbers of these nine types as based on all possible interchanges between all 61 amino acid codons were listed by Holmquist *et al.*[3] and are shown in Table 1. We discuss these results in the light of the significance of nucleotide changes in molecular evolution.

Theoretically, there are 526 possible single-base changes (substitutions) in the 61 codons for the 20 amino acids; 392 produce amino acid changes ('code-altering replacements') and 134 of the changes are silent. Changes that produce chain-terminating codons are omitted from this calculation, because such changes will be rejected. As a result, in a comparison of two homologous genes, one would expect to find on a random basis 25% of silent evolutionary single-base replacements. The calculations for codon changes involving two or three nucleotide replacements are complicated by the fact that such changes will often include more than one change at the same nucleotide site, some of which will be revertants[3]. A value much higher than 25% of silent replacements among single-base changes would show that code-altering changes are adopted more slowly than silent changes because of negative selection. The reverse finding would show evolutionary pressure against the adoption of silent changes as replacements. Table 1 shows that in three of the four summarised examples, code-altering single-base changes are 1.8–3.0 times as likely to be rejected as are silent changes. It could be suggested that silent changes are adopted rapidly because they are advantageous rather than neutral. However, advantageous changes can be incorporated only slowly during evolution because of substitutional load[4], so this reason for the rapid adoption of silent changes is unlikely.

The fourth example consists of genes *B*, *E* and *K* of ΦX174 and G4. These are the three genes that are read as frameshifts in genes *A*, *C* and *D*. Barrell *et al.*[5] and Godson *et al.*[6] concluded that the gene *E* arose at a later stage of evolution than gene *D*. This would be consistent with the much lower percentage of silent changes in gene *E* (ref. 6). Such changes in gene *E* would nearly all produce amino acid changes in the predecessor gene *D*, because third positions of codons in gene *E* are first positions of codons in gene *D*. A similar reasoning can be applied to gene *K* as compared with its predecessors *A* and *C*, and to gene *B*, in which third codon positions are second positions of codons in gene *A* (refs. 5, 6). Therefore, silent changes in genes *B*, *K* and *E* would often be rejected as causing unacceptable amino acid changes in genes *A*, *C* and *D*. Indeed, a markedly low value for the per cent of silent changes might indicate *per se* that a gene is being read by a frameshift in a gene of earlier origin. The results in Table 1 show that with the predictable exceptions of genes *B*, *K* and *E*, the genes in phages ΦX174 and G4 have incorporated silent nucleotide replacements much more rapidly than code-altering replacements.

The question arises, are silent replacements actually neutral, or have they taken place for adaptive reasons, such as a requirement for a specific secondary stucture in mRNA, or a preferential use for certain transfer RNAs in regulating the rate of synthesis of a protein? Modulation of the rate of translation by isoacceptor tRNAs, and adaptation of tRNA pattern to the demands of translation were among the reasons advanced by Kafatos *et al.*[7] to explain the nonrandom use of synonymous codons in rabbit and human β-globin mRNAs. However, such arguments are unconvincing, for each β-globin mRNA has a different list of usage for synonymous codons. It seems highly improbable that closely related mammals would have different requirements for mRNA structure and tRNA usage for the same protein. If this were so, a staggering number of species differences, each necessitating a separate evolutionary pathway, would be needed at the molecular level for the thousands of different homologous proteins in each species. We therefore conclude that silent single-base replacements in the codons of β-globin mRNAs are probably neutral. This simple explanation probably also applies to the other comparisons of mRNAs in Table 1.

We have previously stated[8] that 'if DNA divergence in evolution includes the random fixation of neutral mutations, then the third position nucleotides should change more rapidly, because synonymous mutations are more likely to be neutral'. This prediction agrees with the findings summarised in Table 1, with the exception, for reasons noted, of the 'frameshift genes'. Recently, Kimura[1] has drawn attention to the preponderance of silent replacements over code-altering replacements as evidence for the neutral theory of molecular evolution, based on comparisons of 53 nucleotide positions in human and rabbit β-globin mRNAs plus 84 positions in histone H4 mRNAs of two sea-urchin species. We have extended and expanded Kimura's findings, and Table 1 shows comparisons of 8,469 nucleotide positions.

0028-0836/79/420605—02$01.00

Table 1 Evolutionary replacements in mRNAs and viral genes compared with interchanges in code

		β-Globins	α- and β-Globins	ΦX174 vs G4 genes		Possible interchanges in code table
				In phase	Frameshift	
Single-base	Example					
Degenerate	UUU/UUC	84	64	487	16	134
Recognisable	UUU/AUU	27	78	160	77	392
Per cent silent		76	45	75	17	25
Two-base						
Degenerate	CUC/UUA	2		31		28

Degenerate	UCU/AGC			4		12
Recorded as single-base	UCU/GGC	1	2	29		308
Recorded as two-base	UCU/GUA	2	44	124	8	1,164
Recognisable	UUU/AAG		1	6		82
Totals						
Nucleotides compared		1,323	1,251	5,094	801	10,980
Nucleotide replacements		210	523	1,660	178	8,360
Silent replacements		122	207	894	41	3,012
Per cent silent replacements		58	40	54	23	36

The globin comparisons are of mRNA sequences from refs 7, 9, 10, 11 and 12. The β-globins are of rabbit, human and mouse and were compared pairwise. The α-globin was of rabbit, and was compared with the three β-globins. The gene sequences of ΦX174 and G4 are from refs. 5 and 6. The comparisons of the codon table are from ref. 3, and are the total of possible amino acid codon changes in both directions, excluding changes that involve chain-terminating codons.

It is obvious from results now available that the inaccurate and crude procedure of measuring evolutionary changes in terms of 'minimum base differences per codon' is defective and therefore obsolete.

We thank Dr J. C. Fiddes for supplying aligned comparisons of G4 and ΦX174 coding regions, and Dr Charles Weissmann for the unpublished sequence of mouse β-haemoglobin gene. We acknowledge support for T. H. J. by a grant from NASA.

Note added in proof: Friedman *et al.*[13] compared the sequences of the early regions of polyoma and SV40 genomes. Our examination of their Fig. 4 shows 65% silent single-base changes, and 43% silent replacements in 2,079 nucleotide comparisons with 1,080 replacements.

Human–mouse somatic cell hybrids have proved invaluable in assigning human genes to their respective human chromosomes[1]. To date, the success of this approach has depended on identifying human proteins which are synthesised in hybrid cells containing a small number of human chromosomes. Consequently, chromosome assignment has been limited mainly to human proteins which are expressed in man–mouse somatic cell hybrids and for which a suitable assay, usually electrophoretic or immunological, exists to distinguish between the human and murine homologous proteins. This technique is therefore unsuitable for the assignment of those human genes which are expressed only in differentiated cells and not in hybrid cells. Here, we describe how nucleic acid hybridisation and restriction endonuclease mapping of DNA can be combined to test for the presence of human structural gene sequences within hybrid cell DNA. This method can be used to assign any purified human DNA sequence to a human chromosome, and does not require the DNA sequence to be expressed in man–mouse hybrid cells.

The genes that we have studied are those which code for the $^{G}\gamma$- and $^{A}\gamma$-globin polypeptides of human fetal haemoglobin (HbF, $\alpha_2{}^{G}\gamma_2$ and $\alpha_2{}^{A}\gamma_2$) and those which code for the β- and δ-globins of major and minor adult haemoglobin (HbA, $\alpha_2\beta_2$ and HbA$_2$, $\alpha_2\delta_2$, respectively). DNA fragments containing the β- and δ-globin genes can be detected in restriction endonuclease digests of total human DNA by agarose gel electrophoresis of the digested DNA, transfer of the digest products to a nitrocellulose filter by blotting[2] and hybridisation of the filter with ^{32}P-labelled cloned complementary DNA (cDNA) made from human β-globin messenger RNA (plasmid pHβG1 (ref. 3)). The globin DNA fragments detected have been ordered into a physical map of restriction endonuclease cleavage sites around the human β- and δ-globin genes[4]. Similarly, cloned

cDNA made from human $^{G}\gamma$-globin mRNA (plasmid pHγG1 (ref. 3)) has been used as a nucleic acid hybridisation probe to construct a physical map around the $^{G}\gamma$- and $^{A}\gamma$-globin genes[5].

To assign these genes to a human chromosome, we therefore prepared DNA from a panel of human–mouse somatic cell hybrids, and digested the DNA with a restriction endonuclease which would release the β-related globin genes in DNA fragments of a convenient size for subsequent detection by electrophoresis and filter hybridisation with either ^{32}P-labelled pHβG1 DNA or pHγG1 DNA. The restriction endonucleases chosen were *Pst*I, which liberates the β- and δ-globin genes in DNA fragments of 5.0 and 2.3 kilobase pairs, respectively[4], and *Hind*III, which generates a 8.2-kilobase $^{G}\gamma$-globin DNA fragment and a 3.5-kilobase $^{A}\gamma$-globin fragment[6].

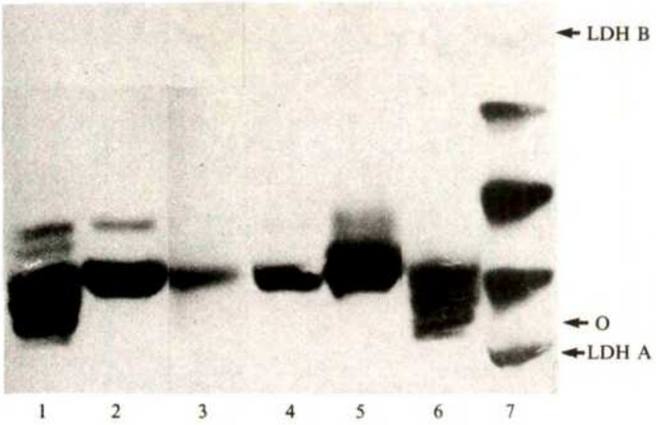

Fig. 1 Electrophoretic analysis of LDH in man–mouse somatic cell hybrids used in this study. Hybrid cell extracts were electrophoresed on cellulose acetate strips and stained for LDH activity as described elsewhere[12]. Cells used were: (1) LBT.2; (2) mouse (3T3 cells); (3) LBT.2 grown in the presence of BUdR; (4) mouse (1R cells); (5) Cl.5; (6) LA.4; (7) human (HeLa cells). The electrophoresis origin (O) and positions of human LDH A and LDH B homotetramers are as indicated. Hybrids LA.4 and LBT.2 exhibit a multiple banded pattern characteristic of cells expressing human LDH A in addition to mouse LDH.

Early in this project we learned that Deisseroth *et al.* had used solution hybridisation of labelled human β- and γ-globin cDNA with man–mouse hybrid cell DNA to show that β- and γ-globin genes were located on human chromosome 11 (ref. 7). We therefore limited our investigation to DNA prepared from the four somatic cell hybrid clones described in Table 1. The hybrid LA.4 has been shown by karyotyping to contain human chromosomes 11 and X (ref. 8); as shown in Fig. 1, this hybrid cell line also expresses human lactate dehydrogenase A (LDH A) determined by the short arm of human chromosome 11 (ref. 9). A subclone of LA.4, termed Cl.5, had lost human chromosome 11 and therefore the ability to synthesise LDH A. A third hybrid clone, LBT.2, contained a human translocation chromosome comprised of the short arm of chromosome 11 and most of the long arm of chromosome 17 (11 cen → 11p15; 17q21 → 17 qter)[9]. This chromosome enables LBT.2 cells to synthesise human LDH A and also codes for the soluble form of thymidine kinase (TK); a gene necessary for the expression of this enzyme has been assigned to the long arm of human chromosome 17 (ref. 10). The fourth cell line was derived by growing LBT.2 in bromodeoxyuridine (BUdR) to select against cells carrying the TK gene; this cell line, termed LBT.2-BUdR, had, as predicted, lost the human translocation chromosome and the ability to synthesise human LDH A.

DNA was prepared from each of these cell lines, digested with restriction endonucleases *Pst*I or *Hind*III and compared with restricted human and mouse DNA by agarose gel electrophoresis, transfer to a nitrocellulose filter and subsequent hybridisation with ^{32}P-labelled pHβG1 or pHγG1 DNA (Fig. 2). In the conditions of hybridisation used, each probe can readily detect its corresponding globin DNA fragments in 10 μg digested human DNA. These human probes show little or no hybridisation to mouse DNA. In a reconstitution experiment in which human and mouse DNA were mixed in varying proportions before restriction and hybridisation, it can be seen that all β-related globin genes could be detected in human–mouse DNA mixtures containing as little as 10% of the normal level of human globin genes. Most important, $^{G}\gamma$-, $^{A}\gamma$-, δ- and β-globin DNA fragments were clearly detectable in hybrid cell lines LA.4 and LBT.2, which contain human chromosome 11 and the short arm of 11, respectively, and were absent in DNA prepared from Cl.5 and LBT.2-BUdR cell lines, neither of which contain chromosome 11. This experiment confirms the assignment by Deisseroth *et al.* of the human γ- and β-globin genes to human chromosome 11 (ref. 7). It also demonstrates that all four β-related globin genes are located within the short arm of chromosome 11 within the region 11 cen → 11p15 (ref. 9). This assignment is formally established by the segregation of the globin genes during selection against the linked TK marker in LBT. 2 cells grown in the presence of BUdR.

Table 1 Man–mouse somatic cell hybrids used in the present study

Hybrid cell line	Human chromosomes identified	Human LDH A	β-Related human globin DNA fragments
LA.4	11, X	+	+
Cl.5	X	–	–
LBT.2	t(11 : 17)(p15; q21)	+	+
LBT.2-BUdR	—	–	–

Hybrid cell lines LA.4, Cl.5 and LBT.2 were grown in RPMI 1640 medium supplemented with 100 μM hypoxanthine, 10 μM methotrexate and 16 μM thymidine. LBT.2–BUdR was obtained by culturing LTB.2 cells for 12 transfers in RPMI 1640 medium supplemented with 30 μg ml^{-1} BUdR. The human chromosome constitution of the cell lines was confirmed by Giemsa 11 and trypsin banding analysis of metaphase preparations (M. Bobrow, personal communication). >90% of LBT.2 cells contained the human translocation chromosome. Detailed quantitative estimates of proportions of LA.4 and Cl.5 cells which contain the indicated human chromosomes are not available. The presence or absence of human LDH A was assayed by electrophoresis of hybrid cell extracts on cellulose acetate (Fig. 1). The analysis of β-related human globin DNA fragments is described in Fig. 2 legend.

This approach to assigning human genes to human chromosomes is simple, fast and only requires that a suitable purified DNA be available as a nucleic acid hybridisation probe. It is also sensitive and enough DNA can be isolated from 10^7 man–mouse hybrid cells to test for the absence or presence of structural gene sequences. In this study the assignment was aided by a very low level of cross-hybridisation between the human globin-gene probes and mouse DNA in the hybridisation conditions used. However, this approach could also be extended to probes which hybridise equally well to both human and mouse DNA, and only requires a restriction endonuclease which generates different electrophoretic patterns of hybridisable DNA fragments from human and mouse DNA. With the advent of libraries of cloned human DNA fragments[11], this assignment procedure could be used to identify cloned DNA fragments from any required human chromosome.

The assignment of human genes to chromosomes by analysing DNA sequences has two major advantages over the alternative approach of studying the production of human proteins in man–mouse somatic cell hybrids. First, it does not require expression of human genes and is therefore suitable for the assignment of genes coding for proteins such as globins which

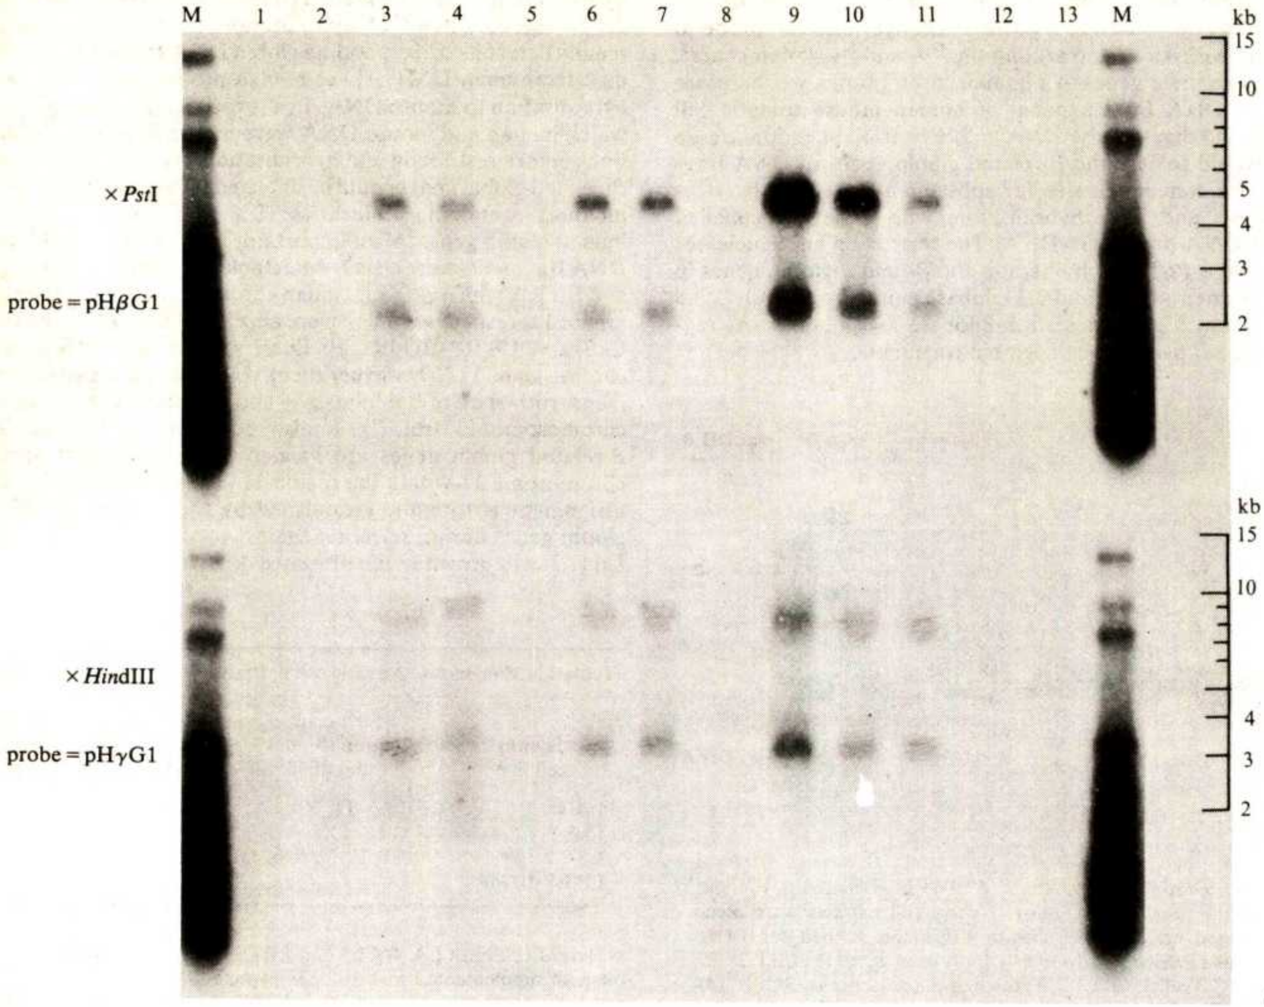

Fig. 2 Analysis of human β-related globin DNA fragments present in restriction endonuclease digests of man–mouse somatic cell hybrid DNA. DNA was prepared from human placenta, from BALB/c mouse brain, from cultured 1R cells and from four man–mouse somatic cell hybrids, using methods described elsewhere[13]. Batches (10 μg) of DNA were digested with endonuclease *Pst*I or *Hin*dIII (Microbiological Research Establishment, Porton Down). DNA digests were recovered, alkali-denatured, electrophoresed through a 1% agarose slab gel and transferred by blotting to a nitrocellulose filter. pHβG1 and pHγG1 DNA were labelled with ^{32}P *in vitro* by nick translation with [α-^{32}P]dCTP (2,000–3,000 Ci mmol^{-1}, Amersham) to a specific activity of 1.5×10^8 d.p.m. per μg DNA. After pretreatment of the filters to prevent nonspecific binding of single-stranded DNA, the filters were hybridised for 2 d at 65 °C in 1 × SSC (saline sodium citrate; 0.15 M NaCl, 15 mM trisodium citrate (*p*H 7.0)) with 30 ng ml^{-1} heat-denatured labelled DNA. Unbound labelled DNA was then removed by washing at 65 °C in 1 × SSC and nonspecific DNA hybrids removed by a stringent wash in 0.1 × SSC at 65 °C. Labelled DNA bands were detected by exposing the filters to X-ray film for 15 d in the presence of an intensifying screen. Full details of the preparation of DNA, restriction endonuclease digestion, gel electrophoresis, DNA transfer, nick translation, filter hybridisation, washing and autoradiography are described elsewhere[13]. Samples electrophoresed were: (1) BALB/c DNA; (2) 1R DNA; (3), (4) separate preparations of LA.4 DNA; (5) Cl.5 DNA; (6), (7) separate preparations of LBT.2 DNA; (8) LTB.2-BUdR DNA; (9) human DNA; (10) 1 : 1 human : BALB/c DNA; (11) 1 : 3 human : BALB/c DNA; (12) 1 : 9 human : BALB/c DNA; (13) BALB/c DNA. The hybridisation markers (M) consisted of 10 pg pCRI DNA × *Eco*RI (13.3-kilobase fragments), 10 pg pCRI DNA × *Kpn*I × *Hin*dII (7.3, 1.3, 0.93, 0.86, 0.64, 0.18, <0.1-kilobase fragments) plus 10 pg pCRI DNA × *Eco*Ri × *Hin*dIII (9.8, 3.4-kilobase fragments); pCRI is the plasmid vector used in constructing pHβG1 and pHγG1 (ref. 3).

are only produced by differentiated cells. Second, in hybrid cells in which both human and mouse homologous proteins are being synthesised, assignment depends on distinguishing between the two species' proteins. If the species difference is solely due to differences in the primary amino acid sequence of the proteins, then assignment will lead to the chromosome localisation of the protein's structural gene. On the other hand, if the difference reflects a species-specific difference in, for example, post-synthetic modification of otherwise identical human and mouse proteins, then analysis of man–mouse somatic cell hybrids could result in the assignment, not of the structural genes for the protein, but of the human modification system instead. Direct analysis of DNA sequences and structural genes in the nuclear DNA of somatic cell hybrids avoids this ambiguity and leads directly to the assignment of the structural gene.

We thank Elinor Tolley for expert technical assistance, Dr M. Bobrow for information on karyotypes, Professor W. Bodmer and David Buck for making hybrid clones available, and Dr P. Little and Professor R. Williamson (St. Mary's Hospital, London) for gifts of purified pHβG1 and pHγG1 DNA.

CUT YOUR AD BUDGET LATELY?

Honesty compels us to admit that you're not alone.

Whenever the cost/price squeeze gets really tough, it's a temptation to regard advertising as a cost... and to cut.

Not at every company, however.

In recent years, a significant change has taken place in the thinking of many management men about advertising budgets. No longer are appropriations cut automatically when the pressure is on.

Why?

For a number of reasons. Among them are:

1. *With the growth of the marketing concept,* advertising is no longer looked upon merely as an expense, but as an integral part of the company's marketing mix.

2. *Firms that maintain advertising during recession years do better in sales—and profits—in those and later years.* That was proved conclusively in studies of five separate recessions made by ABP and Meldrum and Fewsmith.

3. *The cost of a salesman's call today makes it imperative to make maximum use of advertising.* The average cost of an industrial sales call soared to a record $96.79 according to the latest report by McGraw-Hill's Research Laboratory of Advertising Performance. Yet studies show that a *completed* advertising sales call—that is, one ad read thoroughly by one buying influence—literally costs only pennies. Why deny yourself such efficiency?

4. *In some cases, there is no way to reach customers except by advertising.* The "Paper Mill Study" shows (1) the number of buying influences in the average plant is far greater than marketers are aware of, (2) the vast majority of these influences are unknown to salesmen, (3) no salesman has the time to contact all influences even if he knows them.

5. *Selling costs are lower in companies that assign advertising a larger role in marketing products.* So advertising is an investment in profit, just like a machine that cuts production costs.

6. *Memories are short.* There is an estimated 30% turnover every year among buyers. It isn't surprising, then, that lack of advertising contact can quickly result in loss of share of market.

7. *Most down periods turn out to be shorter than expected.* The history of every postwar recession is that it didn't last as long as predicted. Why gamble your market position for short-term gain?

8. *Consider lead time.* Very few products sold to business and industry are bought on impulse. The advertising you are doing—or missing—right now will have its effect years from now.

9. *Advertising works cumulatively.* It would be nice to think that every reader reads all of your ad. We know it doesn't work that way. To be most effective, advertising must have continuity.

10. *Did your competitor cancel his budget, too?* If not, you may be taking a big risk.

11. *Will you lose salesmen?* They know that their chance of getting an order is better if they are backed up by advertising. Can you be sure of keeping them when they learn that that support has gone?

12. *You know better.* Survey after survey of executives shows that they expect a *drop* in sales if advertising stops.

But there is need for efficiency...

whenever advertising budgets are being assembled—never more than in these inflationary times. Significantly, a recent survey shows that nearly 40% of the average budget for advertising to business and industry is invested in business publication space and preparation. That's *more than double* the next largest item.

Why? Because specialized business publications remain the most effective and efficient method of reaching target audiences in business, industry and the professions.

And we can prove it.

Sm–Nd systematics of Lewisian gneisses and the origin of granulites

THE demonstration by Janardhan *et al.*[1] of the purging of H_2O from previously hydrous hornblende–biotite gneisses by CO_2-rich volatiles of possible mantle origin to form pyroxene gneisses is an important development in the study of deep crustal materials. A popular model to explain the chemical peculiarities of granulite facies gneisses (depletion in K, Rb, Th and U; high K/Rb ratios and low Rb/Sr ratios) has been degassing of their precursors during high grade metamorphism[2–5]. The probability of this having been initiated by increase in p_{CO_2} has been recognised by Tarney and Windley[5]. The degassing model received significant support from Nd isotope studies of the Lewisian gneisses from Scotland[6]. There, Sm–Nd dating revealed an age (2,920±50 Myr) of primary separation from the mantle some 200 Myr older than that of chemical differentiation (loss of Rb and U in particular) recorded by whole rock Rb–Sr and Pb–Pb and zircon U–Pb methods. Hamilton *et al.*[6] imply that the repository for Rb expelled from the granulite facies Lewisian is, in part, the tectonically higher amphibolite facies component of that complex, which now has an Rb/Sr ratio that is far higher than is compatible with their $^{87}Sr/^{86}Sr$ ratio at 2,670 Myr ago[7].

There are important geochemical differences between the granulite and amphibolite facies components of the Lewisian complex that are not discussed by Hamilton *et al.*[6] and to which the discovery of Janardhan *et al.* is relevant. The pyroxene gneisses in the Lewisian of the isles of Tiree and Barra have positive Eu anomalies and abnormally high Sr (average, 837 p.p.m.) whereas tectonically higher hornblende–biotite gneisses have negative Eu anomalies and much less Sr (average, 381 p.p.m.) (refs 4, 9 and unpublished data). Both may be features of a primary igneous fractionation of the gneiss precursors, the pyroxene gneisses representing crystallisation under low p_{H_2O} of a precursor tonalitic magma, the hornblende–biotite gneisses the expelled, residual, hydrous magma[8,9]. The complementary patterns could not reflect simple loss of a hydrous vapour phase from the granulites, but could reflect the addition of Sr and Eu to more normal precursors of the pyroxene gneisses from a mantle-derived vapour phase[4], such as that indicated by Janardhan *et al.*[1].

The dilemma is first that a model involving primary igneous fractionation at low p_{H_2O} (implying high p_{CO_2}) of the pyroxene gneisses can as equally account for the K, Rb, Th and U depleted nature of the Lewisian pyroxene gneisses as for their high Sr and positive Eu anomalies[9], thereby making degassing unnecessary as a means of chemical fractionation. Second, that addition of Sr, Eu and presumably other rare earth elements (REEs) from mantle depths in a CO_2 rich vapour phase would have a significant effect on Sr and Nd isotope systems in pyroxene gneisses.

HAMILTON *ET AL.* REPLY—There may be differences in Sr content between granulite and amphibolite facies gneisses in the Scottish Hebridean Islands, but in the much more extensive outcrop on the mainland, Tarney (ref. 1, Table 1), using a much larger sample population, found only a small difference (615 as against 580 p.p.m. Sr) in gneisses of equivalent major element composition. Moreover, studies of REE distributions in the granulites[2,3] show that it is the more fractionated siliceous gneisses which have the more prominent positive Eu anomalies. The rare earth relationships are very similar to those described recently by Arth *et al.*[4] in a Proterozoic gabbro–diorite–tonalite–trondhjemite plutonic suite from South-West Finland, interpreted as resulting from 'wet' hornblende fractionation. Thus they indicate the opposite petrogenetic relationship from that suggested by Drury[5], but are entirely consistent with the isotope systematics which indicate that the dry granulite facies metamorphism reached its peak some 100–200 Myr after the gneisses were formed. This is also consistent with the conclusions of Janardhan *et al.*[6].

With regard to Drury's dilemma, we can only point out that both granulite facies and amphibolite facies samples define the 2,920±50 Myr Nd isochron. Had there been extensive addition of Sm, Nd and other REEs to the granulite facies gneisses, it seems to us most unlikely that the observed Sm/Nd–$^{143}Nd/^{144}Nd$ corelation would have been maintained. Thus, until we see firm evidence to the contrary, we consider that the normally stable REEs have remained relatively immobile during granulite facies metamorphism, while the commonly mobile elements K, Rb, Th and U have indeed been partially removed.

A model for the preferential degassing of the upper mantle

CRITICAL to the model of the depletion of the mantle presented by Hart *et al.*[1] is the assumption that 3.2×10^{-6} ml g^{-1} is an upper limit to the concentration of ^{40}Ar in the mantle source of submarine basalts. This value was obtained from the maximum slope of the upper envelope of data on a plot of ^{40}Ar/^{36}Ar against 1/^{36}Ar. This interpretation ignores the probable significant depletion of initial magma Ar by strong partitioning into CO_2 bubbles and their loss before and during emplacement of magma[2–4]. Further, it has been demonstrated that natural cracks as well as those produced during sample preparation will probably release a considerable part of the CO_2 in vesicles, whose existence has been recently confirmed[5]. Superimposed on this alteration of mantle ^{40}Ar is the variable contamination with atmospheric Ar[3]. Thus the simple interpretation based on the upper envelope of scattered points seems to be invalid. Further, a basic contradiction follows if we apply their value to a limiting model requiring coherency of ^{40}Ar with K transfer; this coherency must apply in their model to the formation of oceanic crust at the ridges as this is the source of the degassed Ar as well as the transfer of K to the sialic crust (see Fig. 1 of Hart *et al.*[1]). Their derived maximum ^{40}Ar concentration of the mantle source of submarine basalts is a factor of 0.04 lower than the coherent ^{40}Ar concentration computed assuming a K concentration of 0.1%. The coherent concentration represents the ^{40}Ar produced from this K concentration in 4,550 Myr. As I pointed out previously[2], this does not require a single-stage mantle history, only coherent degassing at each melting event. Self-consistency demands use of a computed ^{40}Ar concentration of about 8×10^{-5} ml g^{-1} for the initial magma in a limiting coherent model. Correcting for enrichment on partial melting gives an ^{40}Ar concentration of 2×10^{-5} ml g^{-1} for the depleted upper mantle source. Application of this to an estimate of the K concentration of the non-depleted mantle (their Fig. 3) leads to values of >300 p.p.m. even for very high extent of depletion of the mantle. Their other arguments are not qualitatively changed.

HART *ET AL.* REPLY—The concentration of ^{40}Ar in submarine basalts is not critical to the principal observation made in our model calculation of preferential mantle degassing[1]. The main point we stress is the similarity in the ^{40}Ar/^{36}Ar ratio of the atmosphere and non-depleted lower mantle if the atmosphere and sialic crust formed preferentially as a coherent system from the upper mantle. We chose to estimate the ^{40}Ar content of the depleted upper mantle from the ^{40}Ar content of submarine basalts rather than to calculate it indirectly from the K content of the sialic crust and mantle because these values are not well established.

Schwartzman's value of 2×10^{-5} ml g^{-1} for the ^{40}Ar argon content of the mantle is only slightly different from our value of 4.5×10^{-5} ml g^{-1} calculated for the non-depleted lower mantle. Adoption of his calculated value would enhance the similarity in the ^{40}Ar/^{36}Ar ratios of the atmosphere and non-depleted mantle. The concentration of ^{40}Ar measured in submarine basalts is at least an order of magnitude lower than these calculated values. We suggest that this is evidence for an upper mantle depleted in ^{40}Ar relative to the deep mantle and is consistent with the well-established depletion of K in the mantle source of ridge basalt.

There is no evidence that Schwartzman's 'probable significant' degassing of the basalt magma under oceanic ridges by CO_2 bubble transfer is more significant than degassing by basalt–seawater interactions after magma emplacement or than degassing during partial melting and metamorphism in subduction zones and within continental cratons. Because Si and Ca are not partitioned into residual phases or CO_2 bubbles during magmatic processes, the high flux of these elements and ^{3}He observed in geothermal plumes from the Galápagos Spreading Center[2] suggests basalt–seawater interactions rather than bubble transfer are the dominant mechanism for degassing noble gases in ridge basalts today.

We have extensively discussed the effects of atmospheric contamination and degassing on the concentration of ^{40}Ar in submarine basalts and suggest that the surprisingly uniform concentration rules out significant degassing by CO_2 bubble transfer before magma emplacement[3,4]. The ^{40}Ar contents of basalts recovered from depths of over 5,000 m in the Cayman Trough are very similar to those of typical ridge basalts suggesting the ridge basalts have not degassed more than basalts extruded in deep trenches. Basalts with well developed vesicles that have obviously undergone extensive degassing by bubble transfer have been dredged from shallower portions of the ocean and have ^{40}Ar contents up to an order of magnitude lower than the maximum of 3.2×10^{-6} ml g^{-1} we adopted for our model.

The late-Würm Arctic ice sheet

I HAVE recently realised that we did not give Dr John Mercer full credit for his earlier contributions when we wrote our paper *Was there a late-Würm Arctic Ice Sheet?*[1]. In our reference to Mercer's paper *A former ice sheet in the Arctic Ocean?*[2] we should have noted that he was the first to make a mass balance calculation for Arctic ice shelves based on present snowfall over the Arctic Ocean and present iceberg calving rates of Antarctic ice shelves; he had also postulated that late-Würm Arctic ice shelves may have occupied the northern Norwegian Sea; and he had also commented on the evidence for ice from the Arctic Ocean moving southward onto the north slope of Alaska. Mercer's (1970) comments on an ice shelf in the Norwegian Sea were a summary of ideas he had developed more fully previously[3].

Our 1977 paper in *Nature* differed from Mercer's (1969 and 1970) papers in that it developed the idea that ice shelves in the Arctic Ocean, Norwegian, Greenland, and Labrador Seas, and Baffin Bay would have been components of a late Würm Arctic Ice Sheet that also included the Laurentide, Innuition, Greenland, Barents-Kara Sea, British, Scandinavian, and possibly East Siberian Sea grounded ice sheets. This connection is implicit, but not explicit, in Mercer's work. We treated the grounded and floating ice complex as a single, unified dynamic system. As a result, our mass balance calculation included not only the Arctic Ocean (which Mercer treated), but also snowfall over the portions of these fringing ice sheets which drained into the Arctic Ocean and its adjacent seas and bays, and distributed that input along an ice-shelf calving front much further south than Mercer's.

Physicochemical Aspects of Protein Denaturation

by **S. Lapanje**, *University of Ljubljana, Yugoslavia*

Provides the first up-to-date account of protein denaturation to be advanced over the past eight years. It outlines physicochemical aspects, selecting and organizing material to accommodate readers of different educational and professional backgrounds. The approach is pragmatic, giving a concise and accurate review. Readers need only possess a knowledge of elementary physical chemistry and proteins. Accounts of experimental methods are self-contained and no consultation of specialized monographs is required. Particular attention has been paid to the macromolecular properties of unfolded (denatured) proteins, incorporating — in the tables — all important physicochemical data. And, although little unpublished material is included, several physicochemical aspects of protein denaturation have been submitted to a critical analysis; this holds especially true for the thermodynamic analysis of denaturation.

"This monograph is valuable as an unusually well organised survey of a massive literature. I found it stimulating . . . an essential reference work for all those concerned with the stability and dynamics of proteins and provides excellent value for money." Roger H. Pain for **NATURE**

The Natural Vegetation of North America: An Introduction

by **J.L. Vankat**, *Miami University, Ohio*

This book describes the major vegetation types of North America and explains their ecological basis. Individual chapters are devoted to such vegetation types as tundra, coniferous forests, deciduous forests, grasslands, deserts, and tropical vegetation. Each vegetation chapter stresses the role of such environmental factors as climate, soil, topography, and fire. Major plant communities are described in detail and dominant species are fully discussed. Species adaptation are also emphasized to show the interrelationship between vegetation and environment. Each vegetation chapter concludes with a section on human impact, followed by suggested readings.

Fish and Invertebrate Culture: Water Management in Closed Systems 2nd Ed.

by **S. Spotte**, *Sea Research Foundation Inc., and Mystic Marinelife Aquarium, Connecticut*

A completely rewritten edition of this straightforward, concise handbook on water quality control in closed-system environments which focuses on aquariums. It shows how to culture fishes and invertebrates in closed systems by controlling the chemical factors in the environment which bring about change in normal physiology and includes theoretical principles as well as practical water management techniques.

Human Immunology is devoted to an understanding of the ontogeny, mechanisms, regulation and control of immune responsiveness. Since the major histocompatibility complex, HLA, is central to many of these processes, principal emphasis will be on the components of this supergene and on model systems based on the MHC of other species. Full length articles, critical reviews and commentaries, brief communications and technical procedures in the following general categories will be considered for publication:

- Genetic regulation of immune responsiveness
- Histocompatibility and transplantation
- The genetics, differentiation, biochemistry and function of the MHC gene products
- Cell-cell interactions and immunologic processes in the pathogenesis of disease

Subscription rates:
Volume 1, 1980, will be published in four issues. $60.00.

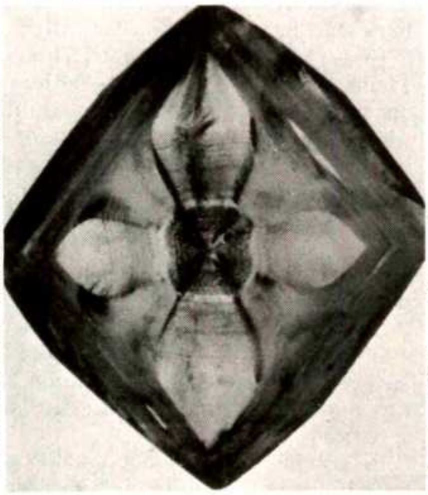
Diamond facets

John Walker

The Properties of Diamond. Edited by J.E. Field. Pp. 674. (Academic: London and New York, 1979.) £32.50; $67.25.

THIS book could reasonably be subtitled "The Special Research Project: A Second Progress Report", for it chronicles the advances made in diamond research since *The Physical Properties of Diamond* was published in 1965 (Clarendon: Oxford). (This latter should have been subtitled "A First Progress Report", of course.) The Special Research Project was established in 1949 by Sir Ernest Oppenheimer of de Beers and Sir Francis Simon of the Clarendon Laboratory to encourage cooperation in fundamental research between the Diamond Research Laboratory and various British universities (and a very fruitful arrangement it has been).



Central section of a centre-cross diamond (height 5 mm)

From Suzuki and Lang, 1976

What the book lacks in my opinion, and what my subtitles were intended to clarify, is a contribution from Soviet and American scientists. Both of these groups have made considerable advances in pure and applied diamond research. American scientists were the first to publish, in the pages of this journal, a report of the successful synthesis of diamond (Bundy *et al., Nature,* **176**, 51-55; 1955). (Indeed the Americans can not only synthesise diamond; they can do it using peanut butter as the starting material — a valuable discovery if ever the EEC establishes a peanut butter mountain.)

This is not to say that the book does not give credit where credit is due — indeed it does — there are copious references to US and Soviet papers. My point is that the American and Russian authors are in a better position to chronicle their own research, especially the latest developments; they would also bring to bear different ideas and perspectives on current problems in diamond research. There may be difficulties in including contributions from them, but there are precedents.

An integral part of the Special Research Project is the annual Diamond Conference, memorable features of which are the quotations it produces. Dr Field reproduces two favourites. I would like to add two more: Q. "What happens at higher temperatures?" A. "The apparatus melts" (H.M. Rosenberg); "As work in the de Beers Laboratory has shown, the de Beers grit is best" (D. Tabor).

To return to the book, it contains twenty chapters, each written by a different author (or authors), under eight headings: solid state (thermal, optical and electronic properties and impurity content), theoretical, surface (adsorbability and optical properties), mechanical (strength, friction, abrasion, indentation, effects of high temperature, internal structure), physics and technology of growth, geology (of the diamond itself and of inclusions within the diamond) and industrial (abrasive and non-abrasive uses). Finally there is a 12 page appendix which tabulates the physical and chemical properties of diamond, including references to the original research.

The chapter on non-abrasive uses of diamond may contain surprises, even for the diamond specialist. We all know about gemstones, and about cutting and grinding uses. Other uses include: windows (small ones of course!) in satellites; high pressure cells in scientific experiments; microtome knives for eye and brain operations; radiation detectors, especially in radiotherapy; thermometers; and as heatsinks for semiconductor devices.

Although it is unlikely that diamonds will become cheap and plentiful, two chapters in the book suggest potential new sources. While Professor Dawson must be gratified that diamonds are now being found in Australia, the late Professor Tolansky's predictions of diamonds on the moon has yet to be verified. (An interesting statistic is that Tolansky inspected 10 million individual diamonds during his studies — he professed to do it as an alternative to watching television!)

Although Professor Sellschop and his team cannot claim to have investigated so many specimens, they report some fascinating results in their activation analysis studies. The impurity content of diamond has long been a topic of interest, and this new technique has provided data of remarkable quality and quantity — particularly on the submicroscopic inclusions which seem to be droplets of the magma from which the diamonds crystallised. The extension of these nuclear methods to the light elements, which so far have been less intensively investigated, is eagerly awaited, as the light elements are more likely to be able to enter the diamond lattice itself.

Another new technique — cathodoluminescence — is providing a wealth of data about point defects (and linear and planar ones too), as well as elucidating the internal structure of diamonds; it is a valuable complement to X-ray and optical transmission techniques. And one of its practitioners, Dr Lang, seems likely to replace Professor Tolansky as a supplier of beautiful photographs of diamond.

Optical micrograph of etched near-central section (2.4 mm square) through natural octahedral diamond

From Harrison and Tolansky, *Proc. R. Soc.,* 1964

It is impossible in the space available to consider in detail all 20 chapters of the book; suffice it to say that the authors are leading lights in their fields.

One of the surprising things about diamond — which in principle is one of the simplest solids one could envisage — is the wealth of studies it has generated, and the continuing exhibition of new and interesting features. Yet we still do not know how it was generated by nature, nor do we understand its frictional behaviour, despite the manifest importance of such topics. But we are trying hard, as the 674 pages of this authoritative book indicate; this is where a scientist must start if he is interested in any facet of diamond. □

John Walker was a Research Fellow at the Universities of Reading and Paris, studying the optical properties of diamond. He is now a microprocessor consultant.

Earthquake phenomena

The Earthquake Handbook. By Peter Verney. Pp. 224. (Paddington: New York and London, 1979). £5.50.

The Earthquake Handbook is an excellent description of earthquake phenomena and fulfills the objectives set out by the author in the introduction: "This is not a technical book: those wanting detailed scientific information [on earthquakes] should consult some of the many excellent works available . . . My interest has been to explain this extraordinary natural phenomenon, referring to the records of past earthquakes, and in the light of modern progress in seismology, to help those who may live in or visit one of the many earthquake-prone areas of the world". The extensive quotations from eye-witnesses to the earthquakes described and the opinions of their contemporaries are certainly the outstanding features in this book, but the author's own contributions are clear and concise. The book is illustrated by an excellent selection of photographs, prints and drawings, all well reproduced. The text, figures, and quotations taken together give as good a description of what an earthquake is really like as any other source short of the earthquake experience itself. However, it should be understood that the treatment is descriptive and the technical aspects of seismology are scarcely touched on. In this sense the title of the book may have been poorly chosen.

The book begins with descriptions of the 1906 San Francisco and 1755 Lisbon earthquakes. These descriptions are amplified in subsequent sections of the book, together with a description of the 1923 Tokyo earthquake based principally upon the eye-witness account of H.W. Kinney, an author and editor who was travelling near Tokyo at the time. Shorter descriptions of the earthquakes at Port Royal, Jamaica (1692), London (1750), Calabria (1783), Messina (1908), Agadir (1960), Skopje (1963) and Alaska (1964) are also included.

The book then gives a very brief account of the various earthquake theories from the earliest mythologies (which generally attributed earthquakes to movement of the animal that was thought to support the Earth) to Aristotle (winds blowing through subterranean passages), Lucretius (rocks displaced in subterranean caverns), Ben Franklin (an electric discharge from a cloud to Earth), and John Michell in 1760 ("earthquakes were waves set up by the shifting masses of rock miles below the surface". Professor Koto of Japan in 1891 was apparently the first to assert that faulting was the cause (and not the effect) of the earthquake. Verney, of course, quotes extensively from those who attribute earthquakes to divine punishment (for example, Royal Society, 1752, "earthquakes only occur when people need chastening"). The section concludes with an elementary description of plate tectonics.

A description of earthquake geography and earthquake effects follows. The latter section is particularly concerned with tsunami (tidal waves generated by earthquakes) but includes discussions of earthquake noises and lights as well as the physiological shock experienced by earthquake survivors and even the motion sickness reported by some.

The basic rules for survival in an earthquake are given in a brief but practical chapter that includes advice on how to prepare for a possible earthquake as well as how to behave during and after the shock. The final three chapters are brief, non-technical treatments of earthquake engineering, prediction, and control. I believe most scientists will find these final three chapters somewhat superficial.

The book is clearly intended for a lay audience, but I believe even seismologists will find the many quotations and general descriptions of real interest. However, the prospective reader is reminded of the author's admonition "This is not a technical book . . .". **James C. Savage**

James C. Savage is a geophysicist in the Office of Earthquake Research, US Geological Survey, Menlo Park, California.

Nutrition and national development

Food and Nutrition Policy in a Changing World. By J. Mayer and J. Dwyer. Pp.300. (Oxford University Press: Oxford and New York, 1979.) £8.25.

LIKE many books which are edited rather than authored this slim volume seems to me to lack the sense of coherence and direction that would seem a *sine qua non* for it to achieve its aim of dissusing the need for placing food and nutrition in the larger context of national development. This failing is doubly said, as it is not merely a book, but a condensation of a five-volume report commissioned from the editors by UNICEF in order to "set forth goals for UNICEF and allied agencies for the next decade".

What use the report will be to UNICEF, only time will tell; I found the book unsatisfactory to read. Partly this was no doubt due to the level at which it was pitched, for as the editors warn: "The specialist would regard the book as nontechnical and somewhat cursory". But it was more than that: it was a sense that it was not a book at all but a collection of disparate chapters loosely edited and fitting together into a scheme which seemed only to exist as the various subheadings in the table of contents.

This is not to say that some of the individual chapters were not quite enjoyable as discrete essays: the editors themselves contributed a chapter entitled "Beyond Economics and Nutrition: The Complex Basis of Food Policy" which was a reprint of their polished critique of approaches to control of malnutrition, first published in *Science*. Some other chapters, notably those by Perisse and Ms Jeliffe, were also well written expositions of the views of the authors. But in this I found the flaw with the book as a whole. Each author seemed to perform a solo item, without reference to his colleagues so that overall the book did not hang together.

I was irritated by such contraditions as Kimm and Donoso repudiating the idea of dietary protein deficiency on page 160, while Winikoff invoked it *en passant* on page 184; or again that Winikoff's chapter advocating megadoses of vitamin A as an effective treatment for vitamin A deficiency was followed by an editorial note pointing out it was a high risk and probably ineffective strategy. Besides such tactical differences, there seemed also to be a difference in grand strategy between the advocates of economic intervention and those who felt that health care was specifically needed.

In general, I would not criticise any scientific work for the divergencies in views it contains. After all, without contradictions there is no science; the great mistakes in nutrition have arisen from professional certainty, not doubt. But the differences in view in this book are not productive ones. There is no air of creative tension between them; on the contrary, the overwhelming impression is that the authors have not even discussed their views with each other. I do not know why this has arisen, I suspect because of a lack of firm editorial control at the centre, and perhaps for some authors a lack of balanced scholarship in the area which they seek to discuss, but it is difficult to judge the extent of scholarship in the space allotted to each author. The editors would have done better to throw out some topics completely (for example, Dr Araujo's ludicrously terse "Nutrition Primer") and enlarge other issues in depth. But they did not, and I suspect the result is a book that will not interest the layman or satisfy the specialist.

John Rivers

John Rivers is Lecturer in Human Nutrition at the London School of Hygiene and Tropical Medicine, London, UK.

NATO ADVANCED STUDY INSTITUTES SERIES

SENSORY ECOLOGY
Review and Perspectives
edited by **M. A. Ali**
Université de Montréal, Canada

This new book goes beyond earlier studies on sense organs by examining the interrelation of sensory function and environmental cues, providing a synthesis of sensory–physiologic and ecologic ideas, and placing the development of sensory systems in its complete ecological perspective. *NATO Advanced Study Institutes Series, Series A: Life Sciences, Volume 18.* 608 pp., 1978, $49.50 ($59.40/£31.19 outside US)

DNA SYNTHESIS
Present and Future
edited by **Ian Molineux**
Imperial Cancer Research Fund, England
and **Masamichi Kohiyama**
University of Paris, France

This volume provides an up-to-date summary of DNA synthesis in a broad spectrum of disciplines, and examines the status of current research and future areas of investigation. *NATO Advanced Study Institutes Series, Series A: Life Sciences, Volume 17.* 1,176 pp., 1978, $75.00 ($90.00/£47.25 outside US)

AMINO ACIDS AS CHEMICAL TRANSMITTERS
edited by **Frode Fonnum**
Norwegian Defense Research Establishment, Division for Toxicology

"This book is made up mostly of short papers, with the emphasis on neurochemical studies of excitatory and inhibitory amino acids . . . As a useful source of up-to-date information and references it should be made available in libraries."
—**K. Krnjević**, *Science*

NATO Advanced Study Institutes Series, Series A: Life Sciences, Volume 16. 760 pp., 1978, $49.50 ($59.40/£31.19 outside US)

THE LIPOPROTEIN MOLECULE
edited by **Hubert Peeters**
Lipid and Protein Department LBS, Belgium

"Clearly, in-depth research reports on lipoprotein compiled in the format of [a] well-displayed book was lacking. Hence this publication fills the gap. This should be a good addition to any medical library and be made available to any biochemist interested in the up to date information on lipoprotein."
—*Revue Canadien de Biologie*

NATO Advanced Study Institutes Series, Series A: Life Sciences, Volume 15. 312 pp., 1978, $32.50 ($39.00/£20.48 outside US)

MAJOR PATTERNS IN VERTEBRATE EVOLUTION
edited by **Max K. Hecht**
Queens College of the City University of New York
Peter C. Goody
Royal Veterinary College of the University of London, England
and **Bessie M. Hecht**
Queens College of the City University of New York

This book brings together the work of both vertebrate systematists and biologists, and presents information on vertebrate evolution above the species level in those areas that are generally applicable to the entire field of vertebrate zoology. *NATO Advanced Study Institutes Series, Series A: Life Sciences, Volume 14.* 918 pp., 1977, $64.50 ($77.40/£40.64 outside US)

PROSTAGLANDINS AND THROMBOXANES
edited by **F. Berti**
University of Milan, Italy
B. Samuelsson
Karolinska Institute, Sweden
and **G. P. Velo**
University of Padua, Italy

". . . a valuable reference source. This book is to be recommended to those seeking an introduction to prostaglandin research, as well as to the collector of reference books on the current status of prostaglandin research in terms of their chemistry, possible clinical application, and roles in a variety of pathological conditions."

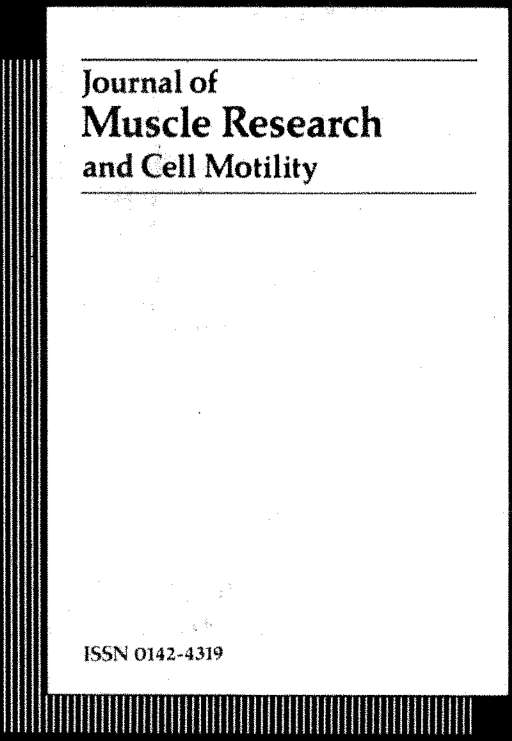
AN IMPORTANT NEW JOURNAL



Journal of
Muscle Research
and Cell Motility

ISSN 0142-4319

Editors:

R.T. Tregear, Biophysics Unit, ARC Institute of Animal Physiology, Babraham, Cambridge.
C.C. Ashley, University Laboratory of Physiology, Oxford.

Editorial Board:

R.H. Adrian, Cambridge;
S. Ebashi, Tokyo;
J. Gergely, Boston;
H.E. Huxley, Cambridge;
S.V. Perry, Birmingham;
T. Pollard, Baltimore;
J.W.S. Pringle, Oxford.

An Important New Journal

The **Journal of Muscle Research and Cell Motility** has as its main aim, the publication of original full-length research papers on any aspect of muscle, contractile mechanisms or cell motility. As research in this area embraces a very wide range of disciplines and techniques the policy of the journal is to encourage any form of practical study whatever its specialist interest, provided only that it contributes to a greater understanding of the way that muscle contracts or cells move.

Forthcoming Papers

Stereochemical aspects of the interaction of nuclectides with myosin and actomysin.
R.S. Goody and W. Hofman

Specific perforation of muscle cell membrane by saponin with preserved SR functions.
M. Endo and M. Iino

Comparison of the cell cytoskeletons in migratory and stationary chick fibroblasts.
R.A. Badley, J.R. Couchman and D.A. Rees

HLA system

The HLA System: An Introductory Survey. Second edition. By A. Svejgaard, M. Hauge, C. Jersild, P. Platz, L.P. Ryder, L. Staub Nielsen and M. Thomsen. Pp. 111. (S. Karger: Basel, London and New York, 1979.) DM 43; $21.75; SFr. 36.

THE HLA system of tissue antigens is acquiring a growing importance in the study of cellular interactions. A coherent, lucid account such as this volume attempts is to be welcomed. The small size of the book (111 pages) in no way reflects a paucity of information. The authors have achieved the combination of brevity and clarity, at the same time providing useful links for readers who may come to the subject from disciplines which do not encompass genetics or human disease.

The scope of work now relevant to HLA is indicated by the contents page, with topics ranging from immune response (Ir) genes to complement, transplantation, transfusion, pregnancy, paternity testing and disease association. The bibliography is comprehensive and commendably up to date. There is a simple but adequate account of the biology of the HLA system, with particular reference to the rôle of the major histocompatibility complex (MHC) in the immune response. This section also includes a summary of current thinking about the specific role of HLA antigens as cell membrane products (? receptors).

There is a good appraisal of the current status of HLA in clinical medicine, including both transplant matching and disease association studies. The authors have summarised these two major applications and give a very honest view of the advantages and disadvantages of applying HLA studies in these areas. There is a short concluding section on methods in HLA typing which is more than adequate for those who may not work directly on HLA but need to know about the general techniques.

This book could be required reading for all non-HLA workers who are proposing to collaborate on HLA studies with the experts in the field. It would save a great deal of time presently spent on lecturing on HLA to various groups of medical and scientific workers who are looking for a simple, understandable introduction to HLA.

Physics of neutron stars

Neutron Stars. By J.M. Irvine. Pp.155. (Oxford University Press: Oxford, 1978.) £7.95.

IRVINE'S monograph is the first book devoted to the physics of neutron stars, the second most extreme endpoint of stellar evolution. The primary content is an informal review of the theory of neutron star structure, with emphasis on our understanding of the physical processes in condensed matter that is needed in order to construct 'realistic' models.

The book begins with a broad outline of stellar evolution, and the mass-radius relationship of neutron stars is estimated in the manner familiar to students of stellar interiors since the work of Eddington. The basic observation of pulses from isolated pulsars is then briefly described, followed by a repetition of the now classic arguments for the identification of pulsars as rotating neutron stars, based on their rate of increase of pulsar periods and the shortness of the period of the Crab pulsar. (The use of the Crab nebula as a box calorimeter to measure the moment of inertia of the central object, an equally crucial part of the identification, is not mentioned.) This is followed by a fairly detailed discussion of glitches in the spindown of the Crab and Vela pulsars along with a review of the starquake model. No mention is made of the 'restless' random walk of the rotation frequency of the Crab pulsar, which is probably also present in the Vela and many other pulsars.

From here, Irvine turns to an outline of cooling processes that can influence the final temperature of a neutron star, both in the deep interior and at the surface. He does a reasonably good job of outlining the significance of superfluidity, superconductivity and the formation of a pion condensate for the cooling rates, a topic which is rapidly increasing in experimental importance as the HEAO-2 observing programme moves forward. An understanding of his discussion requires at least slight acquaintance with the BCS theory of superconductivity. He then turns, in chapter 4, to a brief discussion of neutron star "exteriors". Here, the magnetosphere is treated solely as a source of vacuum magnetic dipole radiation (including the ~ 20% relativistic corrections!), in spite of his mentioning the requirement of there being an electrically significant number of charges in the environs. Irvine then returns to the less controversial realm of condensed matter by describing the peculiar atoms and solids which make up the perfect lattice (density ~ 10^4 g cm^3) expected to form the very outermost layers. This region (often called 'Ruderman's whiskers') is treated with about the same depth but less clarity as is contained in Ruderman's discussion in the

Circle No. 31 on Reader Enquiry Card.

IAU Symposium No. 53 (D. Reidel: Dordrecht, 1974, p117). A few remarks are made on possible radiation of pulsed photons by charges accelerated along polar field lines, including some incorrect remarks on the formation of purely radio pulses because of synchrotron self-absorption of higher emitted frequencies.

The topic of observational appearance is then rapidly abandoned for a return to the interior, with a brief outline of the equation of state including various possibilities in the very high density region (pion condensation, hadronic excited states and cores, and "quark soup"). The application of these equations of state to the calculation of stellar models and the maximum and minimum masses of neutron stars is then outlined, and the book concludes with three brief appendices on methods for calculating the correlations which give rise to superfluidity, as well as a few results from general relativity needed to obtain the 20-30% corrections of Newtonian theory expected for these objects.

Although this book will be mildly useful to specialists in neutron star physics (and somewhat less than mildly useful to those concerned with pulsars as radiating bodies), it suffers from a number of serious problems. It is very badly organised; topics in condensed matter physics are interspersed with astronomical issues (such as scintillation of pulsar radio signals) and with occasional excursions into rudimentary discussion of the magnetosphere. Apparently, the text was written before 1976 and has not been substantially updated; for example, the thick crust neutron stars of Pandharipande, Pines and Smith are not mentioned, and pulsed accreting X-ray sources do not appear at all. This latter omission is especially astonishing, as our real laboratory of neutron star interiors is likely to be the accreting objects in binary systems, not the ". . . vast amount of information . . . buried in the glitch phenomena . . ." of isolated radio pulsars.

Irvine's discussion of the coupling of the isolated neutron star to the outer world is so perfunctory that its omission would have improved the book. For example, I find it difficult to understand the inclusion of the calculation of vacuum dipole radiation in curved spacetime (a 20% correction), while no illustration is given of the orders of magnitude uncertainty introduced by our lack of understanding of the exterior plasma configuration. His discussion of how pulses form is wholly out of touch with modern ideas; however, given the lack of contact between these ideas and the observational details, this topic would also have been better omitted, or dealt with in sufficient depth to illustrate the nature of the problem. His discussion of the interior physics is adequate for the expert, but inadequate as an educational tool for those not already acquainted with theoretical many body physics.

As a reference source, the book is incomplete, and not more up to date than the thorough review by Baym and Pethick (*A. Rev. nucl. Sci.*, **25**, 27; 1975). The flavour of *Neutron Stars* is that of unrevised, rather outdated lecture notes for an advanced course, without the compensation of new ideas or a unified point of view. A monograph which is truly useful remains to be written. **J. Arons**

J. Arons is Professor of Astronomy at the Leuschner Observatory, University of California at Berkeley.

Individual and group differences

The Psychology of Individual and Group Differences. By L. Willerman. Pp.531. (Freeman: San Francisco and Reading, UK, 1979.) Hardback $15; £8.70.
Readings About Individual and Group Differences. Edited by L. Willerman and R.G. Turner. Pp.330. (Freeman: San Francisco and Reading, UK, 1979.) Hardback $14; £8.90; paperback $6.50; £3.80.

THE analysis of individual and group differences, notably those connected with one form or another of ability, has become enmeshed in the confusions of political ideology. Theories that human talents may be inherited, or even that there are human talents, have fallen under a threat of popular disapproval divorced from the scrutiny of evidence or of academic discourse. Given the intolerant tyrannies of the past it is not so hard to interpret the censorship of Copernicus or the curtain drawn over the free development of genetics in Stalin's Russia. But this new censorship, arising from outside the formal apparatus of the state, is more difficult to account for, although in character and effect it is no less insidious. As a consequence, in recent times, academic thinkers willing to argue for the inheritance of intellectual skills have been subjected to strong attacks, often of an unreasoned kind, and their views have been identified with common prejudice. It has sometimes required an act of courage to permit open consideration of the empirical evidence.

The author of this new text on the psychology of individual and group differences pays scant attention to such distractions, and leads the reader straight into the heart of his subject. His report is directed unambiguously to a hierarchical conception of difference. The first chapter deals with the academic background of research, wholly ignoring political overtones or implications. The next two cover some basic elements of statistics and genetics thought necessary for an understanding of the later sections. Inevitably these are brief and probably too difficult for the complete beginner in either discipline, but they do serve as a tribute to the need to master such attendant skills. If no more, they alert the reader to think seriously about the methodological problems that have to be tackled in psychological research.

In the second and major section of the book, the author works patiently through some of the main topics in the current psychology of individual difference: intelligence, genius and their evil counterpart, mental retardation; educational achievement; personality; psychopathology and criminality. Systematically he tackles three basic questions in turn: what is the conceptual status of the difference(s) involved; how far differences are genetically determined; and how far they are environmentally conditioned. At each point the extensive survey of evidence and research is made more valuable because of the careful and critical attention devoted to methodological aspects in the studies reviewed. There is a similarly critical and thorough treatment in the final section which is concerned with three types of group difference: those based on sex, age and race.

In any general text there are bound to be omissions. Here the discussion of occupational and career differences is narrow in scope, excluding a whole range of studies into attitude and performance. There is no reference to the main body of Kohlberg's research into moral differences, or to the investigation of differences in values. The assessment of variety in the forms of excellence is also limited: the work of Piaget, for instance, occupies but two pages, and interesting research by Hudson and others on divergent thinking is altogether ignored. It is perhaps surprising, too, that in the section on group differences there is no separate chapter on social class, and the implications of Bernstein's enquiries into language do not receive appropriate attention in the relatively casual account of conclusions reached by Hess and Shipman. Nevertheless, this book generally provides a scholarly and dispassionate review of a massive research field, and does so succinctly and clearly. It may be recommended to the intending student and teacher of psychology, and also offers the interested lay reader material that is both readable and substantial.

The companion volume of readings is well selected and appropriate to the text. Contents have been skillfully edited to limit the inclusion of spurious material and, in company with the text, they serve to illustrate both the conclusions of research and some of the inherent methodological preoccupations. **John A. Glossop**

John A. Glossop is Lecturer in Education in the School of Education, University of Leeds, UK.

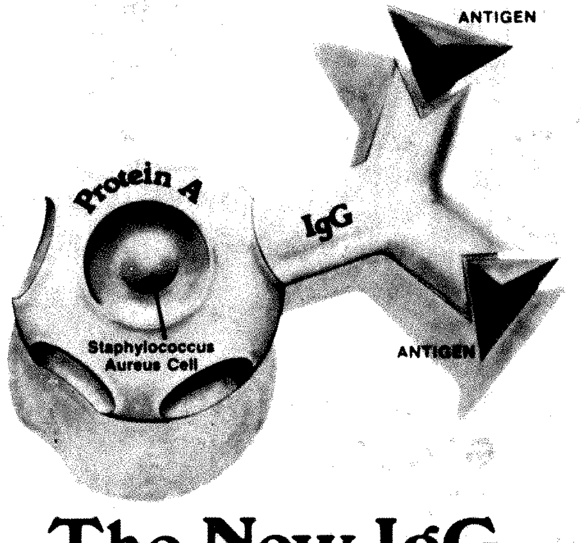
IgGSORB



The New IgG Adsorbing Agent

- 1 minute incubation
- separates antibody-antigen complex from free antigen
- eliminates double antibody
- highly specific for IgG
- separates IgG from crude mixture
- lyophilized
- long term storage life

IgGsorb, the new IgG Adsorbing Agent from the enzyme center inc., simplifies the separation of antibody-complexed antigen from free antigen — eliminates double antibody procedures and reduces incubation time from several hours to minutes. IgGsorb is Protein A, fixed to the walls of inactivated, lyophilized staphylococcus aureus cells. It specifically binds the FC portion of IgG antibody, separating it from the solution and eliminating long incubations where double antibody processes are usually required.

IgGsorb is particularly useful in performing IgG purification and separation of antibody complexes from uncomplexed antigen. IgGsorb binds rapidly within one minute and separates easily by centrifugation or filtration. With a long storage life, IgGsorb has almost universal use and in some cases can replace charcoal and other cumbersome separation methods.

Scope

The Journal of Plankton Research will publish papers dealing with both zoo- and phytoplankton, in marine, freshwater and brackish environments. The three main topics covered are: (1) the ecology (including model studies) of plankton, including larval and juvenile stages; (2) the physiology (including experimental results) of planktonic organisms; (3) the distribution, life histories and taxonomy of planktonic organisms.

Submission of Manuscripts

Contributions falling within the above scope are invited. Papers will not normally exceed 20 pages in length, although in exceptional cases, longer papers will be considered. Manuscripts (the original and two copies) should be submitted directly to the Executive Editor. Guidance notes for contributors may be obtained from the Production Editor.

obituary

Arend Bouhuys

Arend Bouhuys died on board the *Queen Elizabeth 2*, of a sudden and unexpected heart attack, on 15 June 1979, at the early age of 53. He had resigned from his appointment at Yale University and was on his way to Europe to become chairman and professor of the Department of Physiology at the University of Utrecht in his native country.

His untimely death has deprived occupational medicine and respiratory physiology of an active and brilliant research worker who had made an outstanding contribution to environmental lung disease and, in particular, byssinosis or brown-lung disease suffered by textile workers.

Bouhuys was born in Deventer, in The Netherlands, in 1925. He graduated MD at Utrecht in 1948. He spent his early years as a resident in internal medicine and chest diseases and as an instructor in physiology. He soon developed a special interest in pulmonary disease and methods of measuring lung function. At the age of 29 he was appointed head of the Pulmonary Function Laboratory at the University of Amsterdam. He had by then become interested in byssinosis and in 1959 he published the first of a series of original papers on effects of cotton, flax, and hemp dust exposure on respiratory symptoms and lung function.

In 1962 he left The Netherlands to take up an appointment in Emory University School of Medicine in Atlanta, Georgia. Two years later he was made a Fellow of the John B. Pierce Foundation in New Haven and was offered an associate professorship at Yale University where, in 1968, he was appointed full Professor of Medicine and Epidemiology. During his 15 years at Yale his output was prolific. He published 86 original research papers, two books on the physiology of breathing and lung disease and numerous review articles and abstracts. In 1975 he became managing editor of *Lung* which, under his direction, attracted good papers and increased its circulation.

By using computers for recording and analysing respiratory symptoms (by questionnaires) and lung function, he developed sensitive and accurate methods of measuring acute and permanent changes in lung function from exposure to air pollutants. In this way he advanced epidemiological techniques for investigating chronic respiratory disease in communities. His most ambitious study, undertaken by a multidisciplinary team, was of 8,000 community residents in urban and rural districts in Connecticut and a rural population in South Carolina.

Two of his most valuable papers were published a year before he died. One gave new equations based on height, age and weight for predicting normal lung function values in healthy blacks and whites. The other paper was published in *Nature* **276**, 466-471, (1978). It produced evidence from his own and other studies that cigarette smoking and textile dust exposure were far more deleterious to health than out-door air pollution. He concluded that no measurable effects could be expected from further air pollution control with respect to prevalence of chronic bronchitis, asthma and loss of lung function, but, instead, there should be systematic efforts to prevent cigarette smoking and to control exposures to textile dusts and other inhalant risks at work.

In Utrecht he planned to continue research into isolating the causal agent of byssinosis.

If Arend Bouhuys had not been strongly motiviated to apply his considerable skills and energy to the prevention of lung disease, he would have remained a laboratory research worker. Instead, with his co-research workers in various parts of the world, he undertook field studies of textile workers in several countries, including Spain, Holland and the United States. In the U.S. he focussed attention on brown-lung disease, which had been overlooked. His research findings and his own personal commitment helped to establish strict occupational health requirements for US cotton workers through dust control and medical surveillance.

He is survived by his wife, Fenna, who helped him a great deal in his work, particularly in preparing papers; a son and four daughters, two by a former marriage.

R.S.F. Schilling

P.C. Caldwell

The Death of Professor P.C. Caldwell FRS, on 6 June 1979 at the age of 52 saddened his many friends and came while he was still at the height of his powers.

He was born in Warrington and belonged to a family which had lived there for several hundred years and prospered despite suffering heavy penalties for its steadfastness in the Roman Catholic faith. He was sent to Ampleforth School and there his exceptional academic gifts were recognised but these were so varied that the choice of career proved difficult. He finally decided on a scientific career and went as a scholar to Trinity College, Oxford where he studied physical chemistry for his first degree.

After graduating he stayed in Oxford to do research with Sir Cyril Hinshelwood on nucleic acid in bacteria. Together they showed that DNA per cell mass was related to the rate of growth, and hence protein synthesis, and discussed the need for a relationship between nucleic acid and protein, suggesting that two nucleotides would specify one amino acid. This was the first discussion of the coding problem.

From Oxford Peter Caldwell went to work with Professor A.V. Hill and Sir Bernard Katz at University College, London. It was there that be began his main life's work on the application of physico-chemical methods to biological problems. He made the first successful experiments in which micro-electrodes were used to measure intracellular *p*H. This led to a whole field of study in which similar electrodes are used to measure intracellular ion activities *in vivo*. In the course of this work he made the useful discovery that the leg muscles of the crab *Maia squinado* consisted of very large fibres 1-2 mm in diameter.

A.V. Hill believed very strongly that physicists and chemists entering biophysics should be sent to a marine biological station and so exposed to a great range of biological material and problems. It was not surprising, therefore, that Caldwell moved next to the Marine Biological Association's Laboratory in Plymouth and there, and at Bristol University, he continued to make key experiments in difficult and very competitive fields of study, often inventing powerful new techniques. With Sir Alan Hodgkin, Professor R.D. Keynes and other colleagues he played a leading role in the spectacular post-war advances in our knowledge of nerve and muscle.

Among the results of his many studies were: the first determinations of ATP, arginine phosphate and orthophosphate in single cells; providing the first example of a spatially orientated enzyme in a living membrane showing different sensitivities to inhibition on its two sides; and finding, on single crab muscle fibres, the first evidence that *ionised* calcium exists in very low concentrations in cells and that cell activity can be triggered by an increase in this calcium level. At Bristol University he trained a series of postgraduates in research and, with them, made important progress in our knowledge of the influx and efflux of substances from living cells. He was elected FRS in 1975.

Caldwell had many interests to which he gave himself wholeheartedly and in all of these his knowledge was deep and his technical skill so high that he could deal with acknowledged experts on equal terms. An excellent pianist, he was devoted to music and composed about 30 piano sonatas. It was in accord with his character that he was especially attracted by the work of composers who, like Schubert, took a theme and followed it through many variations.

Peter Caldwell's exceptionally gentle and kind personality made him much appreciated by a wide circle of friends. When relaxed he was most entertaining company and he was always helpful in the lives and work of his colleagues and students. He will be widely missed and our deepest sympathy goes to Mrs P.A. Caldwell and their children Helen, Margaret, Philip, Anne and Thomas.

E.J. Denton

John Jaeger

PROFESSOR JOHN CONRAD JAEGER, Emeritus Professor of Geophysics in the Australian National University, died on 15 May 1979 after a long illness, at the age of 71.

Born in Sydney on 30 July 1907, he was educated at the Church of England Grammar School, Sydney, and at the University of Sydney from which he graduated Bachelor of Science in 1928 with first class honours and university medals in mathematics and physics. In that year he went to Cambridge University where he received first class honours in the Mathematical Tripos. Following five years of research at Cambridge in theoretical physics, he joined the University of Tasmania in 1936 as Lecturer in Mathematics, subsequently becoming Professor of Applied Mathematics in that University. In 1942 he was awarded the degree of Doctor of Science in the University of Sydney.

Shortly after the founding of the Australian National University, John Jaeger was invited to accept a Chair and to set up a Department in the Research School of Physical Sciences. He took up his appointment as Professor and Head of the Department of Geophysics in 1952, and remained in that post until his retirement in 1972. Under his direction, the Department of Geophysics developed rapidly into one of the leading research groups of its kind in the world. In 1965, it became the Department of Geophysics and Geochemistry and more recently (1973), was reconstituted to form the Research School of Earth Sciences, at least in part in recognition of the high international reputation that the department established under John Jaeger's leadership.

The direction of development of the deparment was largely based upon his strongly held belief that the application of the basic sciences of mathematics, physics and chemistry, in concert with more conventional geological methods, to the study of the earth, would result in major advances in our understanding of the origin and history of the earth. His recognition of the importance of interdisciplinary fields, together with his ability to attract staff and students, were major factors in establishment of the high reputation of the department, both nationally and internationally, in a relatively short period.

John Jaeger had a most distinguished career as mathematician, physicist and geophysicist. His scientific contributions covered an extraordinarily diverse range of interests, including theoretical physics, radiophysics, ionospheric and solar physics and meteorology, but the main emphasis of his research was in the application of mathematical techniques to a wide variety of theoretical and practical problems, especially the conduction of heat. On establishing the Department of Geophysics in the Australian National University he embarked upon vigorous experimental programmes concerned with heat flow in the Australian continent, and the behaviour of rocks under stress (rock mechanics). John Jaeger was a man of great scholastic achievement; he published more than 130 articles in the scientific literature, and was author or coauthor of six books in applied mathematics and rock mechanics, which are regarded as standard works in their fields. His book (with Carslaw) *The Conduction of Heat in Solids* is widely accepted as a classic in this area.

In recognition of his achievements, Jaeger, in 1954, was elected a Fellow of the Australian Academy of Science, of which body he was Vice-President in 1958-1959, and in 1970 he was elected Fellow of the Royal Society (London). He was also Doctor of Science (*honoris causa*) of the University of Tasmania. In 1971, he was awarded the Rankine Lecture by the Institution of Civil Engineers (London).

John Jaeger was a big man, both physically and mentally. He was a man of great humanity but basically very shy. He never sought the limelight and was extremely modest about his own achievements. He set high standards for himself and expected staff and students alike to strive for excellence. His influence in many fields, including the earth sciences, in Australia and indeed in the world, has been profound. He will be sorely missed.

Ian McDougall

J.B. Birks

DR JOHN B. BIRKS, reader in physics at Manchester University died suddenly on 1 March 1979, a few months after the death of his wife Margaret in a car accident. He leaves a son and daughter.

He was born on 6 March 1920. After graduation from Oxford in 1940 he joined the Telecommunications Research Establishment for the duration of the war. His work there on radar led to his work on microwave absorption in ferrites, when he joined the Department of Natural Philosophy at Glasgow and for which he received his PhD in 1947. An interest in scintillation counters led him into the field of scintillators and the photophysics of organic molecules which became his main scientific interest.

In 1951 he became professor of physics at Rhodes University, South Africa, where he quickly established an active research group. However, his dislike of the developing racial policies made him return to Britain in 1954 as diretor of research at British Dielectric Research. In 1957 he moved to Manchester to resume his work on photophysics and in a few years had built up a large and thriving research group which later, with his encouragement, diversified into electron scattering, lasers, microwave spectroscopy, vacuum ultraviolet spectroscopy and latterly, polymer physics.

An empiricist, he was probably most gifted in correlating the mass of data in the field and extracting the essence. He had a good physical insight and made substantial contributions to his subject. A prolific and fluent writer he published some 180 papers, edited the proceedings of many conferences, e.g. the Rutherford Jubilee International Conference 1961, and the series *Progress in Dielectrics*. He is probably best known for his books *Scintillation Counters* (1953), *Theory and Practice of Scintillation Counting* (1964), *Photophysics of Organic Molecules* (1970) and the two volumes of *Organic Molecular Photophysics* (1974). Several monographs on scintillation counting were widely distributed by several companies in the field. He was a consultant to many companies and national laboratories, in demand as a seminar speaker and a great attender of conferences where he met his many friends who will now sadly miss his stimulating presence. An enthusiast for his subject he was on occasions guilty of going a bit over the top but his friends would readily forgive him.

John Birks was a man of wide culture and liberal humanistic views, and was always prepared to defend what he thought was right and to support his friends. Never an establishment man he clashed with authority on several occasions which possibly affected his career. A most efficient and capable administrator, and an excellent teacher and researcher he had much to offer.

He was a generous host who entertained well and was particularly kind to his students, many of whom came from overseas. He made them feel very much at home, and now, spread around the world, they will be saddened by his death.

The loss of his wife was a great blow. They will both be greatly missed by his son and daughter and their families. I am glad that for 28 years I knew him both as friend and colleague.

Fluorescence, light scatter, cell sorting

COULTER® have a family of compact reliable instruments that can help you investigate a wide range of cytochemical, histochemical and immunological characteristics. They are the COULTER® Model TPS Cell Sorters.

Select from 5 watt, 2 watt lasers, one or two analysis UV capability and other features to meet your research needs.

Study immunological response, the DNA or protein content of a cell, its surface structure, whether it is alive or dead, how big it is and many other things based on laser-induced fluorescence and/or light scattering.

TPS Systems analyse at rates up to 10,000 cells per second. They also physically sort out cells of interest based on operator-selected parameters at rates up to 4,000 per second.

I am interested in hearing more about the COULTER® TPS cell sorters.

Circle No. 17 on Reader Enquiry Card.

In accordance with the provisions of the foundation, papers are herewith invited for 1980 in conjunction with the

HEINRICH WIELAND PRIZE

which is endowed by the Margarine Institute for Health Nutrition, Hamburg, for the promotion of research.

The prize, named after Professor Dr. Heinrich Wieland, the Nobel Prize winner who died in 1957, is awarded annually and is offered for work on the chemistry, biochemistry and physiology of fats and lipids, as well as on their clinical importance and their significance in the physiology of nutrition.

The Heinrich Wieland Prize consists of a „Heinrich Wieland plaque" and the sum of 15,000 West German Marks.

The prize-winner will be selected by a Board of Trustees which consists at present of the following:

Prof. Dr. Karl-Heinz Bäßler, Mainz
Prof. Dr. Wolfgang Gerok, Freiburg
Prof. Dr. Rolf Grüttner, Hamburg
Prof. Dr. Werner Heimann, Karlsruhe
Prof. Dr. Dr. Konrad Lang, Bad Krozingen
Prof. Dr. Dr. h.c. Gotthard Schettler, Heidelberg
Prof. Dr. Dr. Wilhelm Stoffel, Köln
Prof. Dr. Theodor Wieland, Heidelberg
Prof. Dr. Viktor Wolf, Hamburg
Prof. Dr. Nepomuk Zöllner, München

Persons eligible for the HEINRICH WIELAND PRIZE for 1980 are authors of unpublished scientific treatises or treatises published during the period from 1979 to 1980. Papers must be written in German, English or French. All Papers in English or French must be accompanied by a summary of about 3 pages in German. Treatises that have already been awarded some other prize for scientific work are not eligible.

The closing date for sending in Papers for the 1980 award is 1st March, 1980.

A single copy of the Paper must be sent by this date to the following address:
Board of Trustees for the Award of the Heinrich Wieland Prize
Prof. Dr. Alfons Fricker, Ringelberghohl 12, 7500 Karlsruhe 41, West Germany.

The presentation of this year's prize will take place at 10.30 a.m. on 12th October, 1979 in the Adolf-von-Baeyer Lecture Hall of the University of Munich, which is located in Meiserstrasse.

Circle No. 27 on Reader Enquiry Card.

new products: RIA and electrophoresis

These notes, prepared from material provided by the manufacturers, are intended to give an outline of the range of products on the market. Information on further equipment can be found in the insert in the centre of the journal. For more details use the Reader Enquiry Card bound inside the cover.

A feature on laboratory instrumentation will appear in the 22 November issue.

COLLABORATIVE RESEARCH INC.

To complement the established RIA systems for the measurement of cyclic AMP and cyclic GMP, Collaborative Research Inc. have now introduced an RIA system for the detection of cyclic CMP. The Collaborative Research cyclic CMP RIA system is sensitive in the femtomolar range and provides high CMP antigen, cyclic CMP standard, reagents for acetylation and rabbit γ-globulin. These components may also be purchased separately.

Circle No. 80 on reader Enquiry Card.

A.R. HORWELL

Diagnostic Products of Los Angeles have recently added several new RIA kits to their range. These include kits for the assay of aminoglycoside antibiotics netilimicin and sisomicin, as well as testosterone, LH and FSH. These kits possess high sensitivity and specificity combined with low cross-reactivity.

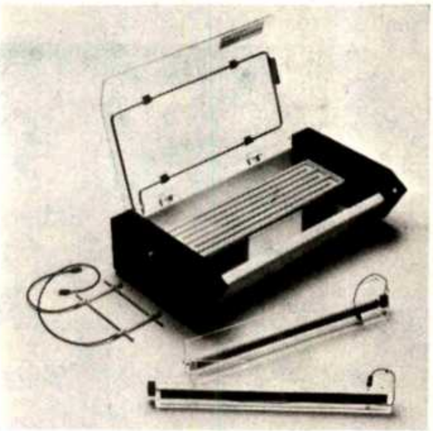
Other new items of interest to laboratories performing RIA techniques are the special heads available on the Sigma 2 and 3 range of centrifuges. These heads have been purpose-designed to cope with the large numbers of tubes used in these assays. The heads are swing-out type; that for the Sigma 2 will hold 20 tubes and that for the Sigma 3 up to 100 tubes. Both centrifuges are available with refrigeration if required; the Sigma 2K refrigerated model, for example, is a compact bench-top model operating down to −10°C.

The Buchler vortex evaporator has proved itself invaluable in laboratories processing large numbers of tubes for RIA. The instrument has facilities for vortexing aluminium blocks containing numbers of tubes, with or without simultaneous vacuum and with either heating or cooling. The heating and vacuum facilities allow for the most rapid possible evaporation of liquids if required. Test tube blocks are available for a variety of tubes, e.g. one to take 90 x 12 mm tubes, or one for 27 scintillation vials.

Circle No. 81 on reader Enquiry Card.

BIO-RAD

The versatile Model 1415 electrofocusing/electrophoresis cell from Bio-Rad is the basic unit in five complete systems for high resolution analytical and preparative electrofocusing, immunoelectrophoresis, zone electrophoresis and preparative DNA separation. Advanced design features of the cell include a large, rectangular cooling platform (125 × 430 mm), a condensation control coil that keeps moisture off lid and gels and dual electrode jacks for running two electrofocusing experiments at once. The platinum ribbon electrofocusing electrodes are detachable, adjustable and are available in two sizes for maximum flexibility in experimental design. The immunoelectrophoresis/electrophoresis electrodes are built into removable buffer chambers that are easily emptied and cleaned. Reagents and accessories can be added as needed for each application, and are available in five convenient applications kits. Many accessories present new designs for substantially improved performance.



The Bio-Rad Model 1415 for flat bed electrofocusing

Circle No. 82 on reader Enquiry Card.

ISCO

The ISCO model 1310 gel scanner transports an electrophoresed gel through the optical unit of an ISCO model UA5 UV monitor, recording UV absorbance of unstained gels or visible wavelength absorbance of stained gels. UV scanning of a cylindrical gel in its original quartz running tube simplifies determination of the minimum time required for maximum resolution and provides accurate quantitation of each peak. Subsequent staining and visible scanning of the same gel then offer increased sensitivity and resolution. Slab gels as well as rod gels can be scanned as can gels affixed to Mylar strips. Scan speed is either 30 or 150 cm per hour and these speeds can be matched up to the recorder speed so that if desired, the gel can be laid on the chart to easily locate zones. UV scanning eliminates the need to remove gels from their running tubes for staining and destaining. The model 1310 will take 25-cm gels which are very inconvenient to stain and scan conventionally because of difficulties in removing them from electrophoresis tubes. ISCO quartz tubes have a wall of 6 mm and tolerances on both inside and outside diameters are held to 0.001 of an inch to assure accurate quantitation. The ISCO scanner can transport two gels simultaneously through the measuring and reference lightpaths of the absorbance monitor. This technique is extremely useful for reducing background empholyte absorbance when scanning isoelectrically focused gels. The ISCO gel scanner is the ideal instrument to use in those biochemical research laboratories which have a column chromatography workload, which would enable them to use the model UA5 monitor, both as a UV detector and as a gel scanner.

Circle No. 83 on reader Enquiry Card.

UNIVERSAL SCIENTIFIC

The compact Universal Scientific Uniscil/Gradipore polyacrylamide gel electrophoresis system is one of the most versatile systems available. Each of the two electrophoresis tanks will accept both rod and slab gels enabling virtually all types of PAGE to be performed. The running tanks incorporate as standard, a buffer circulation and cooling system. Unique to Uniscil are the Gradipore gels. These ready to use pre-cast slab gels contain a continuous polyacrylamide concentration gradient between a variety of concentration limits. The gels achieve separation of macromolecules by molecular sieving in the molecular weight range 3,000,000 to 30,000 to give high resolution. The gels can be used to accept up to 14 samples each for single dimensional running or they can be used as the second of many two dimensional techniques, including isoelectric focusing. The Uniscil electrophoresis range also includes power packs, electrophoretic destainers, gel casting apparatus, gel slicers, and micropreparative attachments.

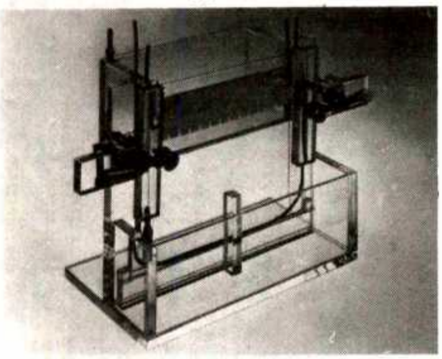
FMC MARINE COLLOIDS

IsoGel from Marine Colloids permits isolectrofocusing in agarose gels. An entirely new procedure, utilising a combination of IsoGel agarose and GelBond film now makes isoelectrofocusing rapid, safe, and convenient. High MW proteins focus almost as rapidly as the ampholytes, and electrofocusing is complete in only 30 min (at 25 watts). Fixing, drying, staining and destaining require only 30 min (total time); and for the first time, 'fingerprinting' of biopsy tissue is possible by the direct IEF 'extraction' technique. GelBond film is an important component of this new IEF procedure. GelBond film is a clear, flexible polyester which firmly bonds IsoGel, as well as other agarose, during all stages of use. It has numerous advantages over glass plates and permits preparation of commercial quality agarose gel plates whenever they are needed. Copies of a booklet describing the agarose IEF technique and product information on IsoGel agarose and GelBond film can be obtained by circling the number below.

Circle No. 85 on reader Enquiry Card.

ATLANTIS SCIENTIFIC

The Atlantis Model HS horizontal submarine gel electrophoresis chamber provides a simple low-cost apparatus for the electrophoresis of most macromolecular substances including DNA, RNA, and proteins. With the gel medium immersed in the buffer solution, the horizontal submarine electrophoresis technique evenly dissipates heat and eliminates hot spots. Combined with the 11-inch long gel tray, the result is clear separation of bands and better resolution than is normally achieved with conventional techniqúes. The system is ideally suited to separation in agarose gels, and may be used preparatively or analytically. Both glass, and UV transparent gel trays are available, accommodating gels of up to 6 mm thick and sample sizes from 5 to 500 μl. The 6½-inch wide gel tray will easily accommodate up to 20 samples in a run. Up to three gel trays (as many as 60 samples) may be loaded in the electrophoresis tank and separated in a single run. The unit provided includes the electrophoresis tank (with platinum electrodes), a glass sample tray, and a 13-position sample well forming comb and comb support.



Atlantis Model VQS vertical slab gel electrophoresis chamber

For high resolution slab gel electrophoresis Atlantis produce the Model VQS vertical slab gel electrophoresis chamber which combines a simplified design with study construction. Easy setup is obtained through the use of silicone rubber sealing gaskets and a single action speed clamping system. This allows rapid mounting of the electrophoresis plates without the bother of sealing grease, removable spacers or pinch clamps. The unit utilises Lucite electrolyte chambers and glass electrophoresis plates which are chemically inert and compatible with most agarose and polyacrylamide gels. A 13-cm electrophoresis path provides excellent resolution. Optional bevelled-top gel plates make two-dimension electrophoresis simple to set up. Electrical connectors are standard banana plugs and the standard apparatus includes one set of glass gel plates with integral 13-place well forming comb, 1.5 mm thick spacers, a plate centering aid and all necessary silicone rubber gaskets.

A Chandos power supply for electrophoresis

CHANDOS INTERCONTINENTAL

Chandos Intercontinental manufacture a wide range of electrophoresis power units which are suitable for use throughout the world. This follows developments which enable a variation of the standard current/voltage stabilisation units to be used also for constant power (wattage). The output of the models available varies from 500 V at 100 mA to 10,000 V at 250 mA, the most popular being 2,500 V at 250 mA. Non-standard models are readily available. Complimentary to production of power supplies Chandos offer a range of horizontal and vertical baths for paper and cellulose acetate — and also a cooled tank for gel or slab electrophoresis. A complete unit incorporating refrigeration is available for high voltage paper electrophoresis and preparative techniques.

For radioimmunoassay Chandos produce the Mini-Assay — a low-cost counting unit primarily designed for radioimmunoassay and which has wide applications in medical research and teaching. The Mini-Assay Type 6-20 comprises a high voltage supply, discriminator and scaler with crystal controlled timer in single unit. Integrated circuits are used in conjunction with other modern techniques and components to make a compact and reliable instrument. The instrument itself is designed to work in conjunction with the 5-43 well counter but it will also operate most types of scintillation detectors with a single cable entry for the high voltage supply and signal. A G-M tube may also be used.

BDH

Tris (hydroxymethyl) methylamine dodecyl sulphate and 4-picoline dodecyl sulphate are available, as high purity materials, from BDH Chemicals as part of the comprehensive range of reagents for electrophoresis. A new catalogue, 'Electrophoresis Materials', is now available. The penultimate section of this catalogue lists dyes and stains. It divides the materials under their various applications, for example, protein stains, tracker dyes and RNA stains, and provides literature references for each. Kenacid blue R and PAGE blue 83 are replacements for Coomassie blue R-250, and PAGE blue G-90 replaces Coomassie blue G-250 from BDH.

TAGO INC.

The use of antisera capable of detecting polyvalent human immunoglobulin levels in sera provides a rapid and reliable means of screening patients for multiple myeloma or other immunological abnormalities. Tago offers goat antisera to polyvalent human immunoglobulins, which recognise not only IgG, IgA and IgM, but also detect the presence of IgD and IgE in combination with either kappa or lambda light chains, to provide broad spectrum screening capability. These polyvalent antisera are synthetic mixtures of antibodies of diverse specification — anti-IgA, anti-IgM, anti-kappa and anti-lambda are mixed to make these polyvalent preparations. Tago offers a choice of polyvalent antisera produced from the whole goat serum and from the immunoglobulin fraction of the goat serum.

Tago antisera to human immunoglobulins

Circle No. 89 on Reader Enquiry Card.

MSE

The Elphormat 3, available from MSE, is a clinical densitometer featuring automatic scanning of up to 12 electrophoresis separations. Scan length is selected digitally and the results are automatically printed out in mg per cent for each protein peak. Results are printed actually on the scan and for those scans containing artefacts or where separations are not complete, the integration points may be marked on the scan by hand, before quantitating. The Elphormat is particularly fast since it produces a complete scan with results in less than 20 s. Sample holders are available to suit most diagnostic systems and these may be specified by the pending purchaser. The sizes of the peaks are related to the size of the albumin peak, for serum protein separations, in order to aid visual interpretation. The Elphormat 3 is the ideal instrument for the clinical laboratory, with a sizeable electrophoresis workload, which requires quantitation.

Circle No. 90 on Reader Enquiry Card.

E-C CORPORATION

The E-C Corporation manufacture a range of electrophoresis items which may be obtained from the UK agents, Camlab Ltd of Cambridge. Of particular interest are the E-C vertical gel electrophoresis system and the EC910 transmission densitometer.

The vertical gel system offers a flexible and versatile gel media system and a complete simple-to-use apparatus for analytical or preparative work. Any gel media including agar, agarose, silica, starch, polyacrylamide and composites of polyacrylamide and agarose can be used. Polyacrylamide gel is recommended and gives superior differentiation because it has the unique capability of predictable pore size regulation to achieve molecular sieving. The E-C vertical cell consists of only two Plexiglass sections which are joined by clamps. This makes it easy to set up and operate. Separation time depends entirely on the complexity of the protein sample.

The EC910 transmission densitometer is a low-cost, compact, and easy-to-operate instrument. It will accept all transparent supporting media and has interchangeable filters in the visible range. The densitometer can be coupled to any potentiometric recorder, but if the recorder does not have integrating capabilities subsequent quantitation of the scan trace can be made using the instrument's built-in electronic integrator. The versatility offered by the EC910 permits the comparison advantages of gel slabs to be maintained throughout quantitation, yet the slit size of 0.3 × 3 mm will scan the geometrical centre of standard 5 mm diameter gel columns.

BOEHRINGER MANNHEIM

The Densitometer 3110 made by Labora Mannheim is available now in the Uk from BCL of Lewes. This inexpensive but precise instrument scans, computes and evaluates proteins, lipids and isoenzymes on cellulose acetate and gel strips. The Densitometer 3110 is easy and quick to use. Within 60 s the Densitometer scans the total surface of a normal pherogram, draws the curves and separates the individual fractions by setting minimas. The scanning range is infinitely variable between 17 and 60 mm and is marked by two light spots. A choice of filters and slit width enables the instrument to scan macro, semi-micro and micro separations on common media which have been stained either blue or red. If the minima set by the instrument are found unsuitable then a second run using manual mode may be performed. As the scan proceeds depressing of the 'man' button sets new minima and the value of the fraction is recorded. The Densitometer 3110 is precise. Zeroing is automatic and as the values of the pherogram are intensified according to the stain, an optimal curve is always drawn. This is essential for correct observation when dealing with different pherograms. Reproducibility of 0.5 can be obtained. As the scan proceeds the instrument simultaneously stores up to 9 individual values which can be recalled at the touch of a button. Values are displayed in the order that the fractions are detected.

M.I. SCIENTIFIC

M.I. Scientific are the United Kingdom representatives for the Helena Laboratories range of scanning densitameters and electrophoresis diagnostic kits. Helena offer a wide range of scanning integrating and computing densitometers for routine and research applications. All systems are designed to scan and integrate a variety of separated patterns on all commonly used membranes including cellulose acetate, thin layer plates, polyacrylamide gel and starch gel. The systems vary only according to their degree of automation, sample accommodation and wavelength range. The list of proven electrophoresis methodologies available from Helena includes the separation and quantification of serum proteins, lipoproteins, alkaline phosphatase isoenzymes (specific liver/intestine test), CPK and LDH isoenzymes, haemoglobins, HDL cholesterol, HbF, simple methods for haemoglobin A_2 and haemoglobin A_{1c} determination (accurate to 0.2%) plus immunoelectrophoresis and immunodiffusion methods.

Circle No. 93 on Reader Enquiry Card.

NEW ENGLAND NUCLEAR

NEN has introduced another in its family of RIANEN assay systems. The ferritin [^{125}I] radioimmunoassay kit is designed to measure ferritin levels in serum or plasma. The kit provides a sensitive and accurate assay system over a wide range of values. This system utilises a solid phase second antibody separation, a feature which reduces the usual second antibody incubation time and results in a firm, highly visible pellet. The kit provides all necessary reagents colour-coded for convenience.

The NEN system for radioimmunoassay of ferritin

Also new from NEN is the EN^{3}HANCE autoradiography enhancer. This product has been designed to greatly reduce the time necessary for researchers to visualise gels by fluorography, at the same time providing improved resolution. Compared to traditional methods, gel preparation is faster, because the procedure has eliminated several steps. The product contains no dimethylsulphoxide, and possesses an unusually high flash point (118°F, 48°C), for improved safety. Rapid visualisation and better detail are provided for carbon-14 and sulphur-35 labelled gels, as well as for lowest level tritium labelled material. EN^{3}HANCE may be used with equal ease for polyacrylamide, agarose, and mixed gels, including those stained with standard laboratory stains and dyes. EN^{3}HANCE technical bulletin available on request.

Circle No. 94 on Reader Enquiry Card.

VITATRON

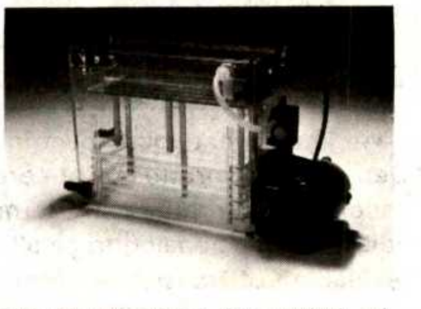
The Vitatron MPS densitometer system is an analysis unit, performing determinations by densitometry, fluorescence absorbance and nephelometry. Scan speed and wavelength selection is variable as is resolution, down to 100 microns. The scan is relayed to a Vitatron 2001 chart recorder where the information can be quantified, or retransmitted to an external integrated system. The MPS densitometer is capable of scanning all types of electrophoretic media, including uncleared cellulose acetate strips. Vitatron MPS is the ideal analytical instrument for those laboratories which may only have a small scanning requirement and who would want their instrumentation to be as flexible in its application as possible.

The Vitatron thinlayer densitometer (TLD) is a purpose-built densitometer intended for the exact quantitation of information from electrophoresis strips and TLC plates. It has the capability of scanning in the transmission, reflectance, fluorescence and fluorescence quenching modes, and will accommodate slab gels up to a size of 20 cm × 20 cm. Wavelength and scan speed are selected by the operator, as is the resolution, down to 100 μm. Information is relayed in an analogue fashion to a chart recorder, which has the facility for retransmitting the output to integrators or other data handling systems. The TLD by virtue of its flying spot analytical system is the instrument of choice for scanning with the highest possible accuracy and precision.

Circle No. 95 on Reader Enquiry Card.

PHARMACIA

The Pharmacia gel electrophoresis apparatus GE-2/4 is the central component of an integrated PAA vertical gel electrohoresis system. The unit is designed for a wide variety of applications including SDS-PAGE, gradient gel elecrophoresis, two-dimensional work and isolectric focusing in both rods and gel slabs of various dimensions. The GE-2/4 will handle 1–4 slabs 80 mm wide and 80 or 140 mm long, 1 or 2 slabs 180 mm wide and 140 mm long, or up to 20 gel rods up to 140 mm in length. Gel slab thickness is 2.7 mm but a 0.7 mm size is available for autoradiographic applications. The unit is moulded in transparent TPX, a tough plastic resistant to all common buffers. The gaskets that locate the gels have been redesigned and are now made in a soft silicone rubber that ensures a leak proof seal and easy cassette fitting. Buffer recirculation combined with an efficient cooling system mean that high power inputs (200 W) can be used to give fast separations and reliable results. The buffer compartments can be isolated by turning a valve when separate buffers are required for IEF work. The GE-2/4 apparatus forms part of the wide range of systems for gel electrophoresis availble for Pharmacia.



The GE-2/4 system for vertical gel electrophoresis from Pharmacia of Uppsala

THE TRUE AFP VALUE?

More than 200 000 AFP
determinations have already been carried out with
Phadebas AFP PRIST®
on amniotic fluid and serum samples.

Our experience tells us that the following parameters are
of utmost importance to obtain a true AFP value.

Phadebas AFP PRIST® gives the following data on those parameters:

- **Detection limit:**
  Samples run undiluted will detect 1 kU AFP/1
- **Dilution of samples:**
  Dilution studies show that determinations of AFP values are constant over a wide range of dilution.
- **Precision:**

	Coefficient of variation	
AFP level	Within assay %	Between assay %
35	8.6	8.9
70	9.0	7.1
105	8.9	8.3
150	10.4	7.7

- **Recovery:**
  Within range 150—450 kU AFP/1
  Recovery 95 ± 18%.
- **Calibration:**
  The AFP-standards are calibrated against the WHO Reference preparation 72/225.
- **Specificity:**
  No crossreaction with human serum albumin or hCG, hPL and CEA.
  No interference with a wide variety of commonly used drugs.
- **Shelf life:**
  16 weeks from date of manufacture.

Phadebas AFP PRIST®

the truly quantitative assay for
alpha-fetoprotein (AFP).

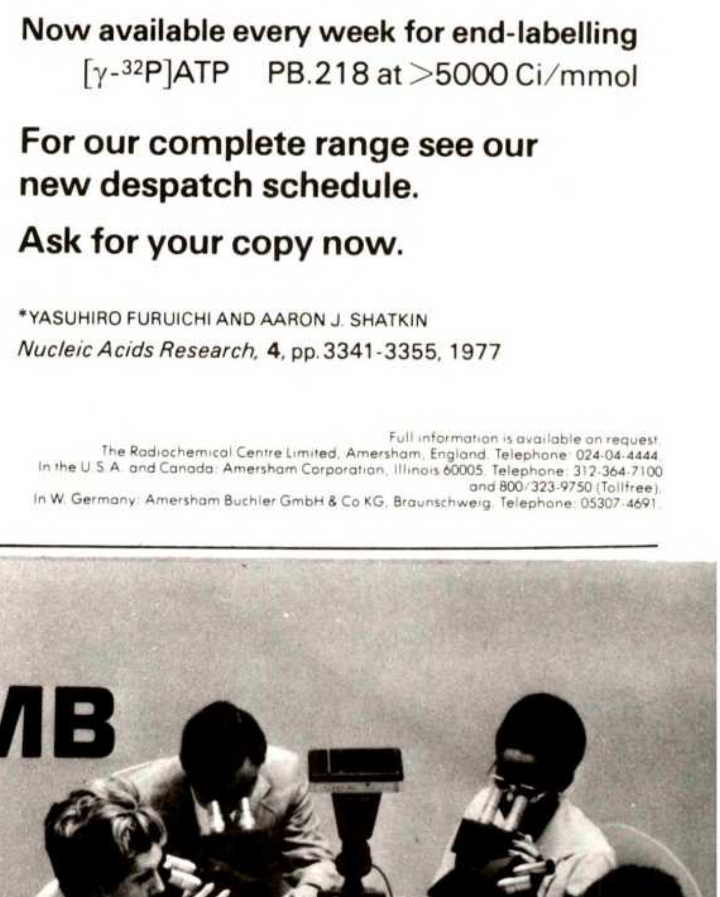
THINK BAUSCH & LOMB EFFICIENCY



Whenever your teaching or consultation requirements call for the versatility and accuracy of simultaneous viewing—think BALPLAN® Conference Microscope efficiency.

Pointing out details and discussing a specimen can sometimes create problems, especially when you and your colleagues or students are trying to evaluate the same specimen at the same time. That's why the BAUSCH & LOMB BALPLAN Conference Microscope can be an important addition to your laboratory. Starting with a basic single-viewing BALPLAN Microscope, you can add up to six additional viewing heads as needed. That's a total of seven viewing stations . . . even a camera station can be added to document your findings.

The results—each person sees identical bright and crisp imagery through separate viewing heads featuring individual focusing controls. And that means there is no wasted time when you call a "BALPLAN Conference". Write today for a detailed catalog or a BALPLAN Conference Microscope demonstration.

CLINICAL ASSAYS/TRAVENOL

Clinical Assays Inc. introduce the new GammaDab [^{125}I] folate radioassay kit, which offers the convenience of room temperature denaturation instead of boiling, and a new step-saving separation system that requires no charcoal. This simple assay is run entirely at room temperature using a single tube. It take less than 30 min of technician's time, reducing total assay time by 20%. Other features include human serum N^5-MTHFA standards and a recovery of N^5-MTHFA typically greater thean 94% at all levels. Binder and separator are combined into one easy-to-pipette reagent consisting of a milk folate binder bound to a pre-precipitated antigen-antibody matrix. Once tracer and sample have competed for sites on the binder, the matrix provides a means of separation of bound from free folate. Assay tubes can be immediately centrifuged and bound tracer counted in the pellet. The kit will assay folate levels in either serum or whole blood. Also from Clinical Assays is the Gamma-Coat [^{125}I] free/total T_4 RIT kit which provides a rapid method of obtaining a free T_4 value. Detailed data sheets on the methods for both folate and T_4 assays may be obtained by circling the number indicated below on the reader enqury card.

BULCHLER INSTRUMENTS

Buchler of Fort Lee, New Jersey has introduced a junior version of its popular 3-1500 power supply to provide a reliable, lower voltage method for electrophoresis applications. This new unit, the DPS-350 uses push-button controls to select the appropriate output ranges and regulations modes. Constant voltage and constant current levels may be selected up to 350 volts d.c. and 100 mA. This output is controlled by a 4-turn potentiometer and offers user full burn-out protection. This unit will automatically switch over from one mode to another whenever the load demand is excessive in the original mode. The large bright IED display makes for easy and precise readings from any reasonable distance within a lab. Buchler produce a full range of electrophoresis products, including a digital 1,000V power supply and analytical and preparative electrophoresis apparatus.

Circle No. 98 on Reader Enquiry Card.

NORTHEAST BIOMEDICAL

Northeast Biomedical Laboratories have published their new catalogue for listing descriptions of viral, bacterial and immunological antisera and conjugates for used in both routine and research laboratories. A new feature of the catalogue is the incorporation of three methods for evaluating the enzyme-conjugated antisera in the ELISA and EIA systems. This is supplemented by a histochemical method using amino-ethyl carbazole for peroxidase and PAP complex techniques. Each group of products is supported by an explanatory text dealing with the preparation of the immunogen. The important advantages of *unabsorbed* antisera and of antibodies to specific Fc fragments are discussed. The catalogue should prove of interest to most laboratories working on the measurement of antibody response where specific immunoglobulins are assayed as well as general laboratories involved in microbiology, haematology and histochemistry.

Savant Speed Vac Evaporator/Concentrator

NOW WITH MAGNETIC DRIVE –

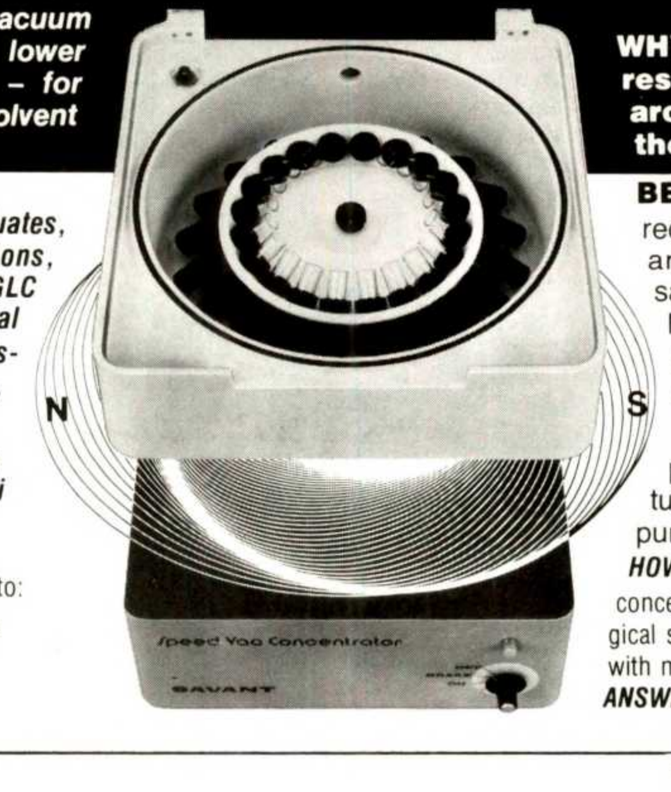
Isolates the upper vacuum chamber from the lower motor drive section – for more efficient solvent evaporation.

WHY — are so many research laboratories around the world using the Savant Speed Vac?

Acid Hydrolysates, Eluates, Extracts, Dialysed Solutions, Preparing Samples for GLC or HPLC in Biomedical Research, Clinical Chemistry, Radioimmunoassays, Mass Spectromotry.

Use with standard culture tubes, tapered tubes, mini vials, silylation vials.

Send for illustrated literature to:
SAVANT INSTRUMENTS, INC.
221 Park Ave.
Hicksville, N.Y. 11801



BECAUSE — 100% sample recovery . . . Evaporates and concentrates at the same time... No splash... No smearing ... 20 to 100 samples at one time.

SIMPLE OPERATION — Load 20 to 100 samples in the rotor, close lid, turn to "on" and turn vacuum pump "on".

HOW ELSE can you evaporate and concentrate small volumes of biological samples in quantity at one time with maximum efficiency?

ANSWER — There is no other way!

Circle No. 18 on Reader Enquiry Card.

newly on the market

Flow cytometer. Ortho Instruments is introducing a highly sensitive versatile cytometry instrument known as the ICP-22 flow cytometer. Easy to operate and maintain, the unit is capable of high resolution fluorescence measurements and allows the use of the widest ranges of dyes available. Its mercury arc lamp gives excitation at wavelengths used by fluorescence microscope users. Cells are presented to the ICP flow cytometer in liquid suspension and transported to the measuring point in the flow cell by suction. A self-contained vacuum pump supplies the suction which reduces the pressure in the waste container at the system's output. The optics of the ICP Flow Cytometer are identical to those of a fluorescence microscope.
Circle No. 71 on Reader Enquiry Card.

Flame-resistant laboratory coats. Gallenkamp. New flame-resistant laboratory coats are now available from Gallenkamp. The coats have a Proban flame retardant finish which meets the requirements of BS 3120 (3119). Proban-treated fabric will resist both the passage of heat and the spread of flames without any smouldering or afterglow. The flame resistance of the coats is not reduced by normal methods of washing or by dry cleaning. Made of cotton the coats are free from static build-up. The coats for both men and women are front fastening with sewn on buttons and two patch pockets.

Marker protein for density gradient centrifugation. Pierce announces the introduction of BSA-Black, an internal standard protein useful for sedimentation coefficient calculations. BSA-Black (amido black 10 β-stained bovine serum albumin) conveniently replaces the use of ^{14}C-BSA to detect BSA in a mixture of other proteins. It does not interfere with the detection of isotopically labelled fractions in the sample and can be easily monitored at 625 nm. BSA-Black, product no. 26640, is supplied in 20-mg packages.
Circle No. 73 on Reader Enquiry Card.

Stain removers. Cambridge Chemical Products. Camco Erado-Sol (liquid) and Camco Erada-Stain (cream) are effective biological stain removers which rapidly remove most stains from hands, glassware and laboratory equipment. They are easy to apply; simply rub in and the stain is gone in a matter of seconds. Rinse with water. Non-irritating to the skin.

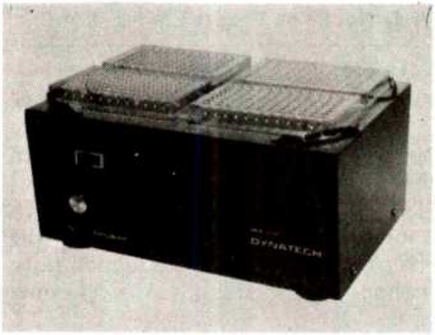
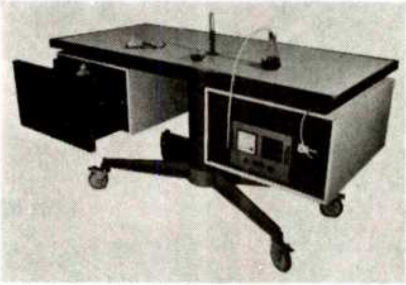
Variable speed micro-shaker. Dynatech have developed an improved microshaker specially designed for shaking all types of microtitre plate. Designated the AM169 Varishaker, the new machine ensures optimum agitation for the re-suspension of cell aggregates and for the mixing of reagents and sera. On the AM169, speed can be reduced or increased as required via a single control, and can be run with up to 4 microtitre plates in position; the plates can be loaded or unloaded without switching off. The vibrational mode is such that all wells receive the same degree of agitation.
Circle No. 75 on Reader Enquiry Card.



The Dynatech Varishaker

Mobile table. Bigneat. Labplan design from Bigneat was the result of a very precise programme of functional research governed by usage. The materials used have been selected for their strength, durability, resistance to acids and solvents. Features of Labplan are the 20-l spillage tray, four double-locking castors, a service channel which runs below the spillage tray to accommodate cables and pipes, and a large drawer for the storing glassware or samples. The open storage shelves can be used for apparatus, thus keeping the work area clear.
Circle No. 76 on Reader Enquiry Card.



The Labplan mobile table from Bigneat

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Enquiry Card bound inside the cover.

Densitometer. Kratos. The SD 3000 spectrodensitometer for the quantitative analysis of thin layer chromatograms is a sophisticated thin layer chromatogram scanner capable of making absorbance and fluorescence measurements of spotted thin layer separations on TLC plates, paper or film, as well as agarose gels, disc gels, slab gels and electrophoretic media. Because of the precision of the SD 3000 and the resolution of the incident light beams, it is equally suited for the analysis of HPTLC plates. The SD 3000 may be operated in either the single beam or double beam ratio mode. The SD 3000 permits the user to choose from an array of compatible accessories according to application and budget.

Materials for radioactive iodination of proteins. Pierce. Iodo-Gen (1,3,4,6-tetrachloro-3α, 6α-diphenylglycoluril, product no. 28600) from Pierce is extremely stable and virtually insoluble in water, allowing rapid iodination in the solid phase with aqueous solutions of I^- and proteins. The incidence of side reactions with this method is negligible. The solubility of Iodo-Gen in chloroform permits 'plating' aliquots of any amount on the walls of the iodination vessel, which can be stored indefinitely before use. Iodinations are terminated by simply decanting the reaction solution from the solid Iodo-Gen. Specific radioactivities of 1×10^5 c.p.m. of ^{125}I per mg of protein and efficiences of 60% are easily achieved. Methyl-*p*-hydroxylbenzimidate · HCl (MPHBIM) product no. 26048) is a water soluble, readily iodinated imidoester. It is moderately stable at *p*H 9.5 and 37°C in aqueous solutions. The amidine linkages formed with proteins are specific for ε-amino groups of lysyl residues and do not alter the net charge of the native protein.
Circle No. 78 on Reader Enquiry Card.

Field/laboratory nephelometer. The Turner Designs Model-40 field/laboratory nephelometer with a flow-through cell attachment is now available. Using a suitable inverter, the Model-40 can be operated from a battery or car cigar lighter socket, to provide reliable turbidity measurements of raw or finished water in less than 5 min from setting-up. Alternative operation as a laboratory or on-line instrument is also possible. The cell has a volume of less than 30 ml. An optional 4–20 mA signal transmitter also permits installation up to 5 miles from a control panel or central office.

Vibration protection for sensitive instruments! MICRO-g™ Tables and Bench Top Units.

Low cost MICRO-g air-isolation systems can reduce building vibration at least 95 to 98%. Even low frequency (7-25 Hz) vibrations that conventional static systems can't handle. The self-leveling top surface is supported on ultra-sensitive air-pistons that adjust automatically to changing loads. Performance is guaranteed.

Standard MICRO-g Tables and Bench Top units cost approximately $1000 and will support equipment loads of over 900-lbs. All that is needed for operation is a compressed air supply or bottled air or gas.

If you're using microscopes, microtomes, interferometers, mask alignment tools or other ultra-sensitive equipment you need to know about MICRO-g systems. There are six standard configurations in a wide range of sizes. Special configurations are readily available. Write for a catalog and price list today.

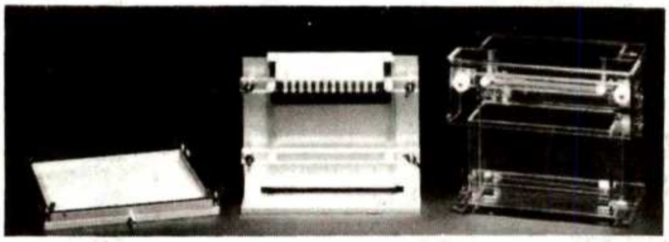
Slab Disc Electrophoresis Kit



Model SJ-1060SDH

secures high resolution and reproductivity of slab gel electrophoresis.

Using our system concept of thoroughly standardized electrophoresis procedures, any laboratory assistant can easily produce the gel, accomplish electrophoresis, and dry to get a permanent electrophorogram in a thin transparent gel film.

Consta Power Model SJ-1065

Electrophoresis and Electrofocusing: Constant Power up to 400 watts, Constant Voltage up to 2,000 volts, Constant Current up to 200 mA.

Built-in power supply for 2 destaining chambers simultaneously operated: Constant Voltage up to 400 volts, Constant Current up to 3 amperes.

Precise digital timer for 999 minutes.

announcements

Awards

The following awards of medals have been made by the Council of the Royal Society. **The Copley Medal to Dr M.F. Perutz,** in recognition of his distinguished contributions to molecular biology; **The Davy Medal** to **Professor J. Chatt,** in recognition of his distinguished contributions to transition metal chemistry and the understanding of catalysis; **The Sylvester Medal** to **Professor G. Higman,** in recognition of his distinguished and profoundly influential contributions in algebra; **The Hughes Medal** to **Professor R.J.P. Williams,** in recognition of his distinguished studies of the atomic structure of proteins in solution using NMR.

The Royal Society Mullard Award for 1979 is to be presented to **E.M. Eltis** and **G.L. Wilde** in recognition of their contribution to the design and development of the Rolls-Royce RB211 turbofan engine. The award is made annually by the Council of the Royal Society in recognition of an outstanding contribution to the advancement of science, engineering or technology which has led directly to national prosperity in the UK.

The Council of the Royal Society has awarded the following three Royal Medals for 1979: to **Sir Charles Frank,** in recognition of his outstanding original contributions to the theory of crystal growth, dislocations, phase transformations and polymers; to **Professor H.W. Kosterlitz** in recognition of his distinguished work on narcotics leading to the discovery of the enkephalins; to **Dr V.E. Cosslett,** in recognition of his outstanding contributions to the design and development of the X-ray microscope and the scanning electron microprobe analyser (scanning electron microscope).

Professor Hermann Lehmann has been awarded The Wellcome Prize for 1979. The Prize, which is in the gift of the Association of Clinical Biochemists, is awarded annually for outstanding scientific contributions to the quality of Clinical Biochemistry as practised in the UK.

The L.R. Wager Prize, for outstanding contributions to the study of volcanic rocks has been awarded to **Dr D.H. Eggler** of the Department of Geosciences, Pennsylvania State University.

The Trustees of the Lady Tata Memorial Trust for research in leukaemia have made the following international awards for the academic year 1979–80. **K. Koubek** (Czechoslovakia); **S. Venuta** (Italy); **B. Azzarone** (Italy); **H. Bhayani** (UK); **E. Harlow** (US); **H. Jacobs** (UK).

The Paul-Martini-Prize 1979 (DM20,000) has been awarded to two German scientific teams. The prize which is intended to promote international cooperation in the field of clinical pharmacology, has been issued since 1969 by the Medizinisch Pharmazeutische Studiengesellschaft e. V. (Frankfurt) in cooperation with the Deutsche Gesellschaft für Medizinische Dokumentation, Informatik und Statistik e. V. (Köln). **Professor Dr. Klaus Breddin,** Head of the Division of Angiology at the Centre of Medicine of the J.W. Goethe University (Frankfurt) and his group receive the prize for a multicentre epidemiological study. **Dr Hans-Jörg Ruoff** of the Department of Pharmacology, University of Tübingen, and his group receive the prize in recognition of a pathophysiological study of the human gastric mucosa and the regulation of gastric secretion by H_1 and H_2 receptor blocking drugs.

The American Institute of Biological Sciences (AIBS) has given its highest honour — the AIBS Distinguished Service Award to **Dr Lee Talbot,** Swiss-based Director of Conservation and Special Scientific Advisor to the World Wildlife Fund.

The recipients of the Wolf prizes for 1979 are: for Agriculture shared by **Professor Jay L. Lush** (Iowa State University) **Dr Sir Kenneth Blaxter** (The Rowett Research Institute); for Mathematics shared by **Professor Emeritus Jean Leray** (College de France, Paris) and **Professor Emeritus André Weil** (Institute for Advanced Study, Princeton); for Chemistry by **Professor Emeritus Herman F. Mark** (Polytechnic Institute of New York); for Physics shared by **Professor George Uhlenbeck** (Rockefeller University) and **Professor Giuseppe Occhialini** (University of Milan); for Medicine shared by **Dr Roger W. Sperry** (California Institute of Technology) **Dr Arvid Carlsson** (Gothenburg University) and **Dr Oleh Hornykiewicz** (University of Vienna).

A memorial service for the late Professor Sir Ernst Chain FRS will be held at the Central Synagogue, Great Portland Street, London W1 on Sunday 21 October at 6.15 pm.

The Meldola Medal for 1978 has been made to **Dr John Evans** for his work on metal cluster compounds. The next award will be made in 1980 to the chemist who, being a British subject and under 30 years of age at 31 December 1979, shows the most promise as indicated by his or her published chemical work brought to the notice of the Council of the Royal Institute of Chemistry, 30 Russell Square, London WC1, UK before 31 December, 1979.

The biennial award in Carbohydrate Chemistry (sponsored by Tate & Lyle Ltd) consisting of an inscribed document and monetary prize of £100 will be made to the Fellow of the Chemical Society who shall have published during the year in question, and in the immediately preceding five years, the most meritorious contributions to the knowledge of any aspect of carbohydrate chemistry, and who, at the date of publication, were under the age of 36 years. The recipient must be a citizen of the UK, and the major part of the relevant scientific contributions must have been carried out and published in the UK. Applications (by 31 October 1979) to S.S. Langer, The Chemical Society, Burlington House, London W1, UK.

Three Corday-Morgan medals and prizes for work in different branches of Chemistry each consisting of a silver medal and monetary award of 250 guineas will be made in respect of the year 1978. These will be made to the chemists of British nationality have published during the year in question and in the immediately preceding five years, the most meritorious contributions to experimental chemistry in their respective fields. Candidates should be under the age of 37 years at 31 December 1978. Applications or recommendations in respect of the year 1978 must be received not later than 31 December 1979 to The Chemical Society, Burlington House, London W1, UK.

Fellows of the Chemical Society should note that the annual award of the Marlow Medal and grant of £100 is based on publications (not necessarily in the Transactions) on any subject normally published in JCS Faraday Transactions I and II. Applicants should be under the age of 33 years on 1 January 1980, and applications may be made by either the candidate or on his behalf by another Fellow of the Society. Application by 1 January 1980 to Mrs Y.A. Fish, Faraday Division, The Chemical Society, Burlington House, London W1, UK.

The Beilby Awards are made to British investigators in recognition of independent, exceptional and original work carried out over a period of years and involving the development and application of scientific principles in any field related to the special interests of Sir George Beilby, (chemical engineering, fuel technology or metallurgy) in their modern interpretations. The Awards are intended to encourage younger men and women (normally under the age of 40). Such work may be brought to the notice of The Convenor of the Administrators, Sir George Beilby Memorial Fund, The Royal Institute of Chemistry, 30 Russell Square, London WC1, UK.

Nominations are invited from Palynological societies and institutions for the award of the Erdtman Medal for the years 1977 and 1979. The chief aim of the award is to accord recognition to outstanding contribution to palynology in its widest sense, embracing botanical, geological, medical, agricultural and other possible aspects. The nominations should reach the Secretary, Prof G. Erdtman International Medal for Palynology Award Committee, National Botanical Research Institute, Lucknow-226001, India by 31 October 1979.

The Naples Zoological Station has arrangements with the Royal Society for British marine biologists to work there on topics of their own choice. Applications for table-time may be made through the Royal Society, the Physiological Society or one of the 10 contributing UK universities (details from the Executive Secretary of the Royal Society, 6 Carlton House Terrace, London SW1, UK). The Royal Society will also consider applications for financial support through its European Science Exchange Programme or from its Browne Fund for marine research.

Up to six Wain Fellowships are available each year to enable younger research scientists to work or study abroad at an academic, industrial or agricultural institution of their choice for a period of up to three months. The Fellowships may be awarded in any science relevant to agriculture, including animal and veterinary sciences. The closing date for applications are 1 April and 1 October annually. Further particulars from the Secretary, Agricultural Research Council, 160 Great Portland Street, London W1, UK.

The Dennis Stanfield Memorial Fund has been established to assist persons of scientific merit to undertake botanical research on tropical African plants. The third award, of £150, will be made in 1980. Application forms from the Executive Secretary of the Linnean Society of London, Burlington House, Piccadilly, London W1, UK by 30 October 1979.

Applications are invited for the 1979 Karl Heinrich Gyr and Heinrich Landis Commemorative Prize. This prize (£500) is awarded annually for practical contribution to the advancement of electrical or electronic science or engineering. Applications for the award should be submitted to the Secretary, The Institution of Electrical Engineers, Savoy Place, London WC2, UK.

The Gottschalk Medal recognises distinguished research in the medical or biological sciences by younger scientists. Candidates must be under the age of 36 years (and not Fellows of the Academy) at the closing date for nominations, and their research must have been carried out mainly in Australia. Applications to The Executive Secretary, Australian Academy of Science, PO Box 783, Canberra City, Act 2601, Australia.

Learned Societies, academies, universities and individuals in industry throughout the world are now being invited to nominate candidates for the Sixth Marconi International Fellowship (a $25,000 grant). The 1980 Fellowship will be made to a person who has made an outstanding contribution to the improvement of communications in developing countries. Applications to Marconi International Fellowship, Aspen Institute of Humanistic Studies, 1919, 14th St, No. 811, Boulder, Colorado 80302.

The Pawsey Medal is normally awarded annually. It recognises outstanding research in experimental physics by younger scientists. Candidates must be under the age of 36 years at the closing date for nominations, and their research must have been carried out mainly in Australia. Applications to The Executive Secretary, Australian Academy of Science, PO Box 783, Canberra City, Act 2601, Australia.

Dr Jesse Roth is to share the Diaz-Christobal Prize with **Dr Pierre De Meyts** following publication of mapping of the residues responsible for the negative cooperativity of the receptor-binding region of insulin, in *Nature* **273**, 504 (1978).

HEART (Heart Exploration and Research in Therapy Ltd) is a new charity dedicated to supporting research into coronary artery disease that has been set up. Initially preference will be given to grant applications covering the field of non invasive diagnosis but applications for funding for work in related areas of coronary artery disease will also be considered. Applications to HEART, 47 Wimpole St., London W1, UK.

Person to person

Visiting scientist, wife and baby would like to exchange their four-bedroomed house in London (Battersea) for a house or apartment (preferably two-bedroomed) in Lausanne, near the Rue du Bugnon, for a period of one year (or less) from January 1980. Contact Hanno Koppel, Jerry Lewis Muscle Research, RPMS Hammersmith Hospital, Ducane Rd, London W1, UK.

Appointments

Dr K. D. Tocher, Coordinator, Management Sciences and Computer Technology, British Steel Corporation, has been appointed to the Chair of Operational Research at Southampton University with effect from 1 May 1980.

The Agricultural Research Council has announced the appointment of **Dr Allen J. Bailey** as Director of its Meat Research Institute at Langford near Bristol, from 1 September 1979.

J.T.M. Taylor has been elected President of the Institution of Mining and Metallurgy for the session 1980–81 in succession to Dr D.A. Temple.

Dr Lewis T. Chadderton Professor of Physics at the H.C. Ørsted Institute of the University of Copenhagen will succeed Dr A.L.G. Rees as Chief of CSIRO's Division of Chemical Physics.

Dr David Smiles has been appointed to head CSIRO's Division of Environmental Mechanics. He will succeed **Dr J.R. Philip** who has been appointed Director of the organisation's Institute of Physical Sciences from February 1980.

Dr A.G. Sykes has been appointed to the Chair of Inorganic Chemistry at the University of Newcastle upon Tyne, from 1 October 1979.

Dr Ian Graham-Bryce, from Rothamsted Experimental Station, has been appointed Director of East Malling Research Station in succession to **Dr A.F. Posnette** who retired in July.

Dr Jeffrey W. Davies of the University of Wageningen has been appointed Head of the Virus Research Department at the John Innes Institute in Norwich with effect from 1 October 1979.

Professor Sir David Phillips has been appointed Fullerian Professor of Physiology at the Royal Institution from October 1979, in succession to Professor Max Perutz.

Professor Keith Vickerman has been appointed to the newly established second Chair in Zoology and head of department in the University of Glasgow, with effect from 1 October 1979.

Lawrence Theodore Threadgold, has been appointed to the chair of Zoology at The Queen's University of Belfast.

Professor Michael Thompson Professor of Experimental Physics at the University of Sussex, has been named to succeed **Dr Frank Thistlethwaite** who will be retiring in September 1980.

APPOINTMENTS VACANT

ANALYST TECHNICIAN (Grade 4) required for Department of Geology, University of Reading. Applicants experienced in wet chemical methods for silicate analysis preferred but those with appropriate experience in general inorganic analysis by atomic absorption, colorimetric and other techniques also considered. Salary according to qualifications and experience in scale £3,018 to £3,657 p.a. (under review). Further details quoting Ref. TN69A, from Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading, RG6 2AH, to whom applications should be sent as soon as possible.

3501(A)

POSTDOCTORAL POSITIONS

Opportunities for experimentalists with background in atomic physics, solid state or materials science, to study interactions of matter with radiation (electrons, photons including synchrotron radiation). Experience in one of these fields desirable. One- to two-year appointments. DM 24,000 per year tax free.

Send application, with references, to: Fritz-Haber-Institut der Max-Planck-Gesellschaft zu Hd. v. Fr. L. Lambert Faradayweg 4-6, D-1000 Berlin 33.

W440(A)

DIRECTOR

Peabody Museum of Natural History

Yale University invites nominations and applications for the position of Director, Peabody Museum of Natural History. Applicants should be recognized scholars qualified to hold professorial rank in one of the three areas of museum activity, Anthropology, Biology and Geology. Demonstrated administrative ability and familiarity with the functions and problems of a research-oriented natural history museum serving both the university and the public are desired.

The Peabody Museum, founded in 1863, serves as an interdisciplinary research and teaching laboratory, as a major repository of scientific collections, and as a university contribution to the life of the community, the latter function including public exhibits, programs and school services and other community-oriented activities.

The Director presides over a board of curators, all of whom are full-time Yale faculty, and various administrative and operational support services. An Assistant to the Director and Business Manager aid the Director in museum administration. Museum support is derived both from the university budget and, to an increasing extent, outside funding. The development of new research programs, centered in the museum, will be important tasks for the Director.

Yale University is interested in increasing the number of qualified women and minority group members in its faculty and welcomes applications from women and minority group members.

Nominations, applications and supporting material should be sent, before November 23rd, 1979, to:

Robert B. Gordon, Chairman, Directors Search Committee Department of Geology and Geophysics

Yale University
Box 2161 Yale Station
New Haven, Conn 06520

Yale University is an Affirmative Action Employer. All interested persons are encouraged to apply.

IMPERIAL COLLEGE UNIVERSITY OF LONDON

DEPARTMENT OF PHYSICS

LECTURESHIP IN PHYSICS

BLACKETT LABORATORY

Applications are invited for a number of lectureships in physics from candidates whose research interests lie in the fields of astronomy, optics and laser physics, solid state physics, spectroscopy and theoretical physics.

The successful candidates will be attached to the appropriate research section within the Physics Department. Salary on the scale £4,333 to £8,992 (under review) with superannuation plus London allowance of £740 p.a.

Applications with curriculum vitae, list of publications and the names of two referees should be addressed to Professor D.J. Bradley, Department of Physics, Imperial College, London SW7 before 8th November 1979.

Applications are invited for a

POST-DOCTORAL RESEARCH ASSISTANTSHIP

OPTICS SECTION

The successful candidate will engage in a theoretical research programme in the field of laser dynamics and non-linear optics. Applicants should hold a Phd degree (or equivalent) or be in the process of completing their doctoral thesis. A reasonable background in theoretical physics is a prerequisite and previous experience in quantum electronics would be an advantage. The appointment will be for two years and the salary will be at an appropriate point on a scale starting at £4,333 (under review) plus £740 London allowance and superannuation.

Applications, accompanied by at least two references, should be sent to Dr G H C New, Optics Section, Department of Physics, Imperial College, London SW7 2BZ.

3522(A)

UNIVERSITY OF ASTON IN BIRMINGHAM

DEPARTMENT OF BIOLOGICAL SCIENCES

RESEARCH FELLOW

Applications are invited for the above post from suitably qualified comparative physiologists to work either in the area of experimental diabetes and carbohydrate metabolism or in some aspect of fish physiology.

Informal enquiries may be made to Professor A J Matty, Head of Department of Biological Sciences (Tel Ext 6083). Commencing salary will be within the range £4,333 to £5,488 per annum on a scale rising by annual increments to £7,521 per annum.

Application forms and further particulars may be obtained from the Staff Officer (quoting Ref No 379/6) University of Aston in Birmingham, Gosta Green, Birmingham B4 7ET (tel 021 359 3611 Ext 201) to whom applications should be forwarded not later than 9th November, 1979.

3505(A)

UNIVERSITY OF BRISTOL

LONG ASHTON RESEARCH STATION

MATHEMATICAL MODELLER

Required to participate in the developmen of a model to simulate the growth and yiel of winter wheat.

The appointee will be located at Lon Ashton Research Station, will join inter institute working parties concerned wit the structure and mechanisms of th model, and will be responsible for it algebraic formulation and for some dat collation and analysis to obtain necessar parameter values.

Will also be expected to visit or stay at othe institutes on occasion.

The appointment is for a 3 year period.

Starting salary according to qualification and experience. Scientific Officer (£3,28 to £5,085) or Higher Scientific Office (£4,727 to £6,211). Non-contributor superannuation scheme.

Minimum Qualifications 2(1) Honou degree in Physics, Biophysics or Applie Mathematics, with a strong interest in pla biology. At least two years releva experience for H.S.O. grade.

Further particulars an application for from the Secretary, Long Ashton Researc Station, Long Ashton, Bristol, BS18 9A to whom applications should be sent by 8 November, 1979.

3513(A)

CERRO TOLOLO INTER-AMERICAN OBSERVATOR

EXPERIMENTAL PHYSICISTS OR ASTRONOMERS

The observatory (operated by th Association of Universities for Research i Astronomy, Inc. in Tucson, Arizon under contract with the U.S. Nation Science Foundation) has staff positio available for experimental physicists astronomers. The ideal candidates w have strong backgrounds in detect technology, low noise solid sta electronics, cryogenic techniques an preferably advanced degrees and j related experience.

The selected candidates will ha responsibility for the design an development of detector systems an associated hardware for the observatory astronomical infrared research programs

Salaries and position levels negotiab according to qualifications.

The principal work location is in t coastal city of La Serena, Chile. Liber fringe benefits, including overse allowance, observatory provid reasonable rent housing close to work, well as opportunities to participate in t observatory's research programs.

Candidate selections will be made January 31 and June 30, 1980. Se Resume to: Personnel Office, 950 Cherry Ave., P.O. Box 26732, Tucson, A 85726

W447(A)

Editor of Nature

Applications are invited from those wishing their names to be considered for this appointment, which will become vacant at the end of this year.

A brief account of past career, qualifications and experience considered relevant should be sent in writing to:

nature

The Publishing Director,
Macmillan Journals Limited,
4 Little Essex Street,
LONDON WC2R 3LF

3504(A)

THE UNIVERSITY OF NEWCASTLE UPON TYNE

EPARTMENT OF OCCUPATIONAL HEALTH AND HYGIENE

pplications are invited from men and omen for the post of:

TEMPORARY LABORATORY TECHNICIAN (RESEARCH)

o work in the Research Unit of the above epartment. The project involves the vestigation into the variation in normal ng function. Candidates should have an NC, OND or relevant City and Guilds ertificate in Physiology or Applied iology and have had three years' perience including training period. The st is tenable until 30th June, 1981. Grade salary scale £3,122 to £3,553 per annum.

Written applications, giving details of e, qualifications, experience, present lary and the names and addresses of two ferees to Dr J.E. Cotes, Department of ccupational Health and Hygiene, 21 laremont Place, Newcastle upon Tyne, E1 7RU. 3492(A)

WITHINGTON HOSPITAL

Nell Lane,
Manchester M20 8LR

SCIENTIFIC OFFICER

r National (UK) Reference Laboratory r Anticoagulant Reagents and Control.

Graduate with good honours degree in ochemistry or allied sciences required. lary £4,035 rising to £4,935.

Work will be concerned with the actical application of techniques in the oduction, research and development of boratory standards.

Enquiries to the Director of the National K) Reference Laboratory for nticoagulant Reagents and Control.

Y3481(A)

OXFORD UNIVERSITY

Applications are invited for the post of Medical Laboratory

SCIENTIFIC OFFICER

to work in the Nuffield Dept of Clinical Medicine/MRC Molecular Haematology Unit on the control of haemoglobin synthesis. The work involves studies on globin chain synthesis in thalassaemia and other inherited disorders in man as well as experimental work in sheep. Applicants should hold either a degree in biochemistry or related subjects or HNC in medical laboratory sciences. Salary on the Whitley Council Scale, £3,768 to £5,391 (£4,125 to £5,817 wef 1.1.80) depending on age and experience.

Full job description and application forms from: The Departmental Administrator, Nuffield Dept. of Clinical Medicine, Room 5801, John Radcliffe Hospital, Headington, Oxford. Closing date for applications is 1.11.79. 3495(A)

UNIVERSITY OF OXFORD

DEPARTMENT OF BIOCHEMISTRY

DEPARTMENTAL DEMONSTRATORSHIP

It is proposed to appoint a Departmental Demonstrator as soon as possible. The salary will be on the scale £3,775 to £5,008 p.a., according to qualifications and experience and with membership of U.S.S. The appointment is for a period not exceeding 3 years. The successful candidate will be expected to take part in departmental teaching and to conduct his or her own research.

Applications (3 copies) including the names of two referees, should be sent not later than 30th November, 1979 to:

The Administrator, Department of Biochemistry, South Parks Road, Oxford OX1 3QU. 3532(A)

GLASSHOUSE CROPS RESEARCH INSTITUTE

has vacancy in

PLANT PHYSIOLOGY DEPARTMENT

for scientist to initiate research programme on plant membranes and their properties.

Appointment in

HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER

grade depending on qualifications and experience. Salary scales £4,727 to £6,211 (HSO) or £5,876 to £7,864 (SSO). Applicants should have First or Upper Second class Honours degree in appropriate subject and two years experience in study of biological membranes, or equivalent experience. Non-contributory superannuation scheme.

Further details and application forms on request. Applications to Secretary, Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, West Sussex, BN16 3PU, by 7 November 1979. 3497(A)

POST DOCTORAL POSITION — MEMBRANE BIOLOGY

Available January 1980, to investigate the membrane proteins of red cells infected with malaria and malarial parasites. Preference will be given to candidates with previous experience in membrane isolation and characterization of membrane proteins using biochemical, immunologic and/or electron microscopic techniques.

Send three letters of recommendation, curriculum vitae, and a statement of research interests to: Dr Irwin W Sherman, Department of Biology, University of California, Riverside, Calif. 92521. An Equal Opportunity/Affirmative Action Employer. W436(A)

UNIVERSITY OF SHEFFIELD

ELECTRON MICROSCOPY TECHNICIAN (Grade 5)

required for the

DEPARTMENT OF HUMAN BIOLOGY & ANATOMY

Applicants should have experience in the operation, and at least basic maintenance of transmission electron microscopes. Experience in biological specimen preparation, while valuable, is not essential. Salary on scale £3,700 to £4,320 p.a.

Please send details of qualifications, experience and the names of two referees to the Administrative Officer (Personnel), (Ref. S1362/N), or write informally to Professor R. Barer, Department of Human Biology and Anatomy, the University, Sheffield S10 2TN. 3401(A)

THE UNIVERSITY OF NEBRASKA-LINCOLN

BIOCHEMIST

Postdoctoral position available December 1 for research on the genetic control of cell differentiation. Our system utilizes 8 mutants affecting pigment production in cultured chick embryo pigment cells. Electrophoretic approaches will be used including PAGE, iso-electric focusing and 2-D separations. Previous experience in electrophoretic techniques required.

Appointment renewable annually with beginning salary $13.000. Send curriculum vitae and three letters of recommendation by November 1 to: Dr John Brumbaugh, School of Life Sciences, The University of Nebraska-Lincoln, Lincoln, Nebraska 68588.

Affirmative Action/Equal Opportunity Employer. W403(A)

Reactor Physics

We require a Research Officer whose main concern will be reactor safety studies with the CEGB Regional Scientific Services laboratories at Bristol.

Applicants should be in their mid-twenties with a good Honours degree in a science discipline. Experience in reactor physics is not essential, but candidates must have an appreciation of reactor plant construction and operation. Candidates will need to be able to run computer programs, compare and develop methods of analysis, interpret the results, report their findings lucidly, and stimulate whatever action is necessary in order to improve the performance of Magnox and AGR plants in the South Western Region. On the job training will be available where appropriate.

Salary will range from £5530, and may be on a scale rising to £8950 if you have sufficient relevant experience. Working conditions are excellent in newly built laboratories.

To apply, please write or phone for application form AF/1 from the Personnel Manager, Bedminster Down, Bridgwater Road, Bristol BS13 8AN. Telephone Bristol 648236 (during office hours). Forms should be completed, quoting reference P463/79/N, and returned by 5th November, 1979.

Central Electricity Generating Board
South Western Region

3479(A)

THE NATIONAL INSTITUTE FOR
HIGHER EDUCATION, LIMERICK

APPLIED MATHEMATICS LECTURER AS4 – 061

Applicants should have special competence in the area of numerical analysis and demonstrated expertise in the applications of mathematics. The person appointed will contribute to the development and operation of existing and new courses to degree and post-graduate levels.

A post-graduate qualification in a relevant area is desirable.

Salary Scale: £8,119 to £10,366 per annum.

Application forms, available from the Personnel Office, The National Institute for Higher Education, Limerick, Ireland, should be completed and returned by *2nd November, 1979.* 3485(A)

THE UNIVERSITY OF NEW ENGLAND

Armidale, New South Wales

DEPARTMENT OF AGRONOMY & SOIL SCIENCE

LECTURESHIP IN SOIL SCIENCE

The Division of Soil Science within the Department of Agronomy and Soil Science is responsible for undergraduate teaching of Soil Science in the Faculties of Rural Science, Resource Management, Arts and Economic Studies. Research and postgraduate training within the Division is concerned with various aspects of soil chemistry, biology and physics in relation to soil genesis, fertility and management.

The appointee will lecture and organise practical classes in introductory Soil Science courses. Supervision of advanced student projects will also be required. An appointee is sought in the areas of Soil Biology and/or Soil Management (soil conservation, pollution, reclamation, etc.) and preference will be given to persons in either of these areas having training in Soil Science and experience in teaching and research. The appointee is expected to take up duties in February 1980.

Salary: $A16,291 to $21,402 p.a. Assistance will be given with travel and removals.

Applicants in the UK, Europe and America should forward their applications, and ask their referees to forward their reports, without delay to the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, from whom conditions of appointment can be obtained. An additional copy of application only should be sent to the Staff Officer, University of New England, Armidale, NSW 2351, Australia, quoting Position No. 424.

Applications close 31 October 1979. 3496(A)

AGRICULTURAL RESEARCH COUNCIL

FOOD RESEARCH INSTITUTE

Scientific Services & Development Division

CHEMIST/PHYSICIST

A Scientific Officer is required to join a team of three in the Mass Spectrometry Group to use different types of MS and GC/MS for the analysis of samples sent to the Group in its role as the central ARS Mass Spectrometry Service.

A pass degree or HNC in chemistry or physics is required together with knowledge and practical experience of mass spectrometry and high resolution gas chromatography.

Salary:
From 1st August 1979: on a scale £3,289 to £5,085.
From 1st January 1980: on a scale £3,591 to £5,486.

Five-day working week and flexible working hours scheme operated. Transport facility available mornings and evenings.

Further particulars and application form from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA quoting reference 79/13. Closing date: 1st November 1979. 3512(A)

NMR POSTDOCTORAL POSITION

Applications are invited for postdoctoral work on the NMR of systems of chemical and biological interest, under the direction of Professor Eric Oldfield. Fourier transform spectrometers equipped with widebore superconducting magnets, operating at 360, 220 and 150 MHz, are available for use on the following projects: 1) Deuterium NMR of specifically ^{2}H-labelled membranes. 2) Phosphorus-31 NMR studies of protein-lipid interaction in model and biological membrane systems. 3) High-resolution ^{13}C and ^{2}H NMR spectra of proteins in solution and in the crystalline solid state. 4) NMR studies of metal ion nuclei in solution and in the solid-state, with special emphasis on systems of biological importance (such as ^{57}Fe, ^{67}Zn).

Applications consisting of a curriculum vitae, list of publications and letters from three references should be sent to Professor Eric Oldfield, School of Chemical Sciences, University of Illinois at Urbana, Urbana, Illinois 61801, USA. The University of Illinois is an Equal Opportunity/ Affirmative Action Employer. W449(A)

OCEANOGRAPHY CHAIRMAN

Applications are invited from persons with an earned doctorate, teaching, and research experience. Administrative experience is desirable, but not mandatory. Starting date January 1, 1980 or August 1, 1980.

Old Dominion is a state university. The Oceanography Department offers programs leading to the MS and PhD degrees with concentrations in biological, chemical, geological, and physical oceanography, as well as some undergraduate service courses. The departmental emphasis is on research and graduate teaching. The department has at present 10 faculty and 110 students. From 2 to 4 additional faculty may be added in the next three years.

Applicants should submit a curriculum vitae and a list of three references before November 15, 1979, to Professor Chester E. Grosch, Department of Oceanography, Old Dominion University, Norfolk, VA 23508. An Affirmative Action/Equal Opportunity Employer. W445(A)

STUDENT/JUNIOR TECHNICIAN

equired in busy Clinical Pharmacology Department, to assist in the general unning of the laboratories. Duties will nclude the care of instruments and quipment, ordering and checking of upplies and participation in the research ctivities of the department.

Knowledge and experience of general aboratory equipment essential. Day elease granted for relevant studies. Salary 2,235 to £3,501 plus £352 LW according to ge and qualifications.

Apply to the Secretary, Cardiothoracic nstitute, Fulham Road, London, SW3 HP, stating age, qualifications, xperience and the names of two referees. lease quote ref CP1/79. 3508(A)

POST DOCTORAL SCIENTIST is equired to fill a vacancy in the Radio-herapy Research Department of the nstitute of Cancer Research. The work of he Department involves the study of the iological effects of radiation and ytotoxic drugs on mouse tumours and on uman tumour xenografts, making use of issue culture techniques to assess *in vivo* esponses. The specific project is the levelopment of *in vitro* cell cloning echniques for the direct testing of chemo-ensitivity in human tumours and familiarity vith tissue culture and pharmacology vould be an advantage. The appointment vill be for an initial period of 3 years, with a ossibility of extension. Starting salary in ange £4,261 to £5,332 p.a. plus London llowance of £502 p.a. Applications in luplicate with the names of two referees to he Secretary, Institute of Cancer esearch, 34 Sumner Place, London SW7 NU, quoting ref 300/G/18. 3526(A)

UNITED KINGDOM ATOMIC ENERGY AUTHORITY

PHYSICISTS AND MATHEMATICIANS

are needed by the Safety and Reliability Directorate at Culcheth, Warrington to work in multi-disciplinary teams on a variety of technical studies and research on the safety of all types of reactor systems, but with special emphasis on fast reactor problems. Theoretical studies of reactor behaviour under fault conditions are carried out in association with relevant experimental studies undertaken at other establishments. The work involves Hydrodynamics, heat transfer, reactor physics, computing and many branches of classical physics, and the overall aim is to establish safety philosophy through identification of important problems, followed by their resolution in ways that can be applied to reactor design and environmental planning. In following this aim there is an extensive programme of collaboration with many overseas countries.

Applicants of either sex, should have a clear interest in reactor safety technology, or in the related field of reliability technology. The demands of the work are appropriate to people with academic abilities appropriate to good honours degree standard. A short introductory period will be allowed, but candidates will be expected to demonstrate at an early date their abilities for tackling the problems involved.

Appointments will be in the Science Group, Higher Scientific or Senior Scientific Officer levels. Applicants should normally have one of the following qualifications:

(a) a degree in a Scientific, Engineering or Mathematical subject
(b) degree standard membership of a professional institution
(c) HNC or HND in a Scientific, Engineering or Mathematical subject
(d) alternative qualification equivalent to at least (c) above.

For Higher Scientific Officer appointments, applicants with a 1st or 2nd class honours degree and a minimum of 2 years post graduate experience may be considered. Other applicants with alternative qualifications and at least 5 years appropriate post qualification experience, are not necessarily excluded from consideration.

For Senior Scientific Officer appointments applicants should normally have a 1st or 2nd Class honours degree, with a minimum of 4 years approved post graduate experience.

Rates of Pay as from 1 January 1980

Higher Scientific Officer	£5,455 — £7,210 p.a.
Senior Scientific Officer	£6,780 — £9,315 p.a.

Starting salaries within the scales may be enhanced to allow for good honours degree and/or appropriate postgraduate experience.

At least four weeks annual holiday, plus public holidays: Contributory Superannuation Scheme: five day week.

Write for application form to:

Personnel Officer
United Kingdom Atomic Energy Authority
Safety and Reliability Directorate
Wigshaw Lane
Cuclheth, Warrington, WA3 4NE

Quoting reference B44/J14

Closing date for the return of application forms: 7 November 1979.

3482(A)

CONTINENTAL PHARMA

DRUG METABOLISM AND PHARMACOKINETICS

A vacancy has recently arisen for a

GRADUATE SCIENTIST

to join the Drug Metabolism Section of
CONTINENTAL PHARMA'S RESEARCH CENTRE.

The work involves the study of absorption, distribution, metabolism and excretion of potential drugs in animals and man. Experience in experimental design, development of new bioanalytical methods and computer handling of the data is emphasized. The section is well equipped for liquid scintillation counting, gas-liquid and high pressure chromatography and mass-spectrometry.

The *ideal candidate* will be a senior graduate scientist with experience in the relevant field in industry or university. Such a candidate with adequate knowledge and qualifications might be asked to take charge of the expanding unit of Drug Metabolism and Pharmacokinetics.

A working knowledge of French in an asset.

The Research Centre is situated within easy reach of Brussels but will soon be moved to pleasant surroundings in the country. 20 miles from Brussels.

Written applications, giving details of qualifications and experience, should be addressed to:

DIRECTOR BIOLOGICAL RESEARCH
CONTINENTAL PHARMA
RESEARCH LABORATORIES
B-1830 MACHELEN (Bt), BELGIUM

THE SOPHIA JEX-BLAKE CHAIR OF PHYSIOLOGY

TENABLE AT THE
ROYAL FREE HOSPITAL
SCHOOL OF MEDICINE

The Senate invites applications for the above Chair. Applications (10 copies) should be received by the Academic Registrar (214920N), University of London, Malet Street, London WC1E 7HU, from whom further particulars should first be obtained.

Closing date Tuesday 20 November, 1979. 3523(A)

GENETICIST: To conduct research in molecular genetics of human or other vertebrates and to teach molecular and human genetics. The level of appointment is at the Assistant or Associate Professorship and will depend on qualifications and experience. Interested persons should apply with complete curriculum vitae, including a statement of research and teaching interests, plus the names and addresses of three references.

Applications will be accepted through December 31, 1979 and should be addressed to: Geneticist Search Committee, Department of Genetics, University of California, Davis, California 95616. The University of California is an equal opportunity and affirmative action employer and invites applications from all qualified individuals. W439(A)

UNIVERSITY OF LEICESTER

DEPARTMENT OF BOTANY

Secondary product production by plant tissue cultures

A vacancy exists for a

RESEARCH TECHNICIAN

post in association with the above project. The post will be a Grade 3 limited tenure (two years) position on the following salary scale: £3,122 to £3,553. Candidates with appropriate qualifications and, if possible, experience in plant cell or tissue culture should apply to Professor H. Smith, Botany Department, University of Leicester, Leicester LE1 7RH. 3433(A)

Toxicology and Laboratory Staff

We are committed to develop our already substantial efforts in Toxicology and Occupational Health. These are devoted to the protection of our customers, our employees and the environment.

To support the planned programme of work, we have a number of posts for Toxicologists, Assistant Toxicologists and Laboratory Technicians. These will be based in a new, purpose built, fully equipped building on the Western outskirts of London.

For the posts of **TOXICOLOGISTS**, applicants should have the necessary qualifications and experience to make an immediate contribution to the work of a specialist team, including the supervision and training of junior staff.

Applicants should have:
✻ a science degree with preferably a post graduate qualification.
✻ proven ability to give sound professional advice at senior level on a wide range of toxicological issues.
✻ a successful record of leading work in one or more areas of experimental toxicology.

Applicants should be familiar with:
✻ the critical assessment of scientific data.
✻ the identification and solution of applied biological research problems.
✻ the application of toxicological principles to the regulation and control of chemical exposures.

For the more junior posts of **ASSISTANT TOXICOLOGISTS**, applicants should have the necessary qualifications and experience in applied biology to enable them to:
✻ give immediate help to senior colleagues in the production of critical data reviews.
✻ design and perform experimental studies.
✻ advise on the safe manufacture and use of a wide variety of products.

Applicants should have:
✻ a science degree.
✻ a knowledge of bio-medical effects of chemical substances.
✻ an interest in a full career in toxicology, based on a firm foundation of in-service training.

For the TOXICOLOGIST posts, applicants should be aged about 30 to 40 years. For the ASSISTANT TOXICOLOGIST posts, applicants should be aged about 22 to 28 years.

For the posts of **LABORATORY TECHNICIANS**, applicants should be able to assume immediate technical responsibilities in a biological research laboratory.

They should have experience in:
histo-pathology haematology
bio-chemistry animal husbandry techniques

Applicants should have science 'A' levels, be qualified to HNC level in medical laboratory technology (or be studying for such a qualification). They should be interested in pursuing a career in experimental toxicology and have a flexible approach to in-service work and training.

BP

Starting salaries will depend on qualifications and experience. There are excellent benefits which include a non-contributory pension scheme, excellent staff restaurants, sports and social facilities.
Please write for an application form which, for the TOXICOLOGIST posts, can be supplemented with a curriculum vitae, to:
Sue Bartholomeou, Central Recruitment,
The British Petroleum Company Ltd.,
Britannic House, Moor Lane, London EC2Y 9BU.

3534(A)

STANFORD UNIVERSITY

GEOCHEMIST —PETROLOGIST

The Department of Geology in the School of Earth Sciences invites applications for a faculty position beginning September, 1980. Areas of interest include (but are not imited to) geochemical processes in the crust and mantle of the earth including sotope geochemistry, thermodynamics, kinetics, element distribution and phase equilibria studies. Teaching responsibilities might include graduate and undergraduate courses in geochemistry and igneous petrology. Level of appointment is open, but we are particularly interested in a creative young person, with a well-established record in research.

Applications should include (1) a resume of education, professional experience, and published research; (2) a brief statement of plans for future research, and (3) the names of 4 referees. Send to: Prof. J.G. Liou, Department of Geology, Stanford University, Stanford, CA 94305, by December 1st, 1979. Stanford University is n equal-opportunity/affirmative-action mployer. W329(A)

BLOOD GROUP REFERENCE LABORATORY

SENIOR SCIENTIFIC OFFICER

The Blood Group Reference Laboratory is a Central Reference Laboratory for the National Blood Transfusion Service. This laboratory is a substantial producer of blood grouping reagents of human and animal origin. In the near future significant changes in manufacturing procedures are foreseen with changes in processing, the use of hyperimmune donors and *in vitro* cultures of lymphocytes as new sources of material. It is anticipated that this laboratory will be increasingly involved in monitoring quality of grouping reagents from a variety of external sources.

A Senior Scientific Officer is sought to take charge of all aspects of production and quality control of blood grouping reagents and to be responsible for new developments and research in these areas. Salary: £8,182 to £10,097 (increase pending) plus £502 L.W. Further information may be obtained from Dr A.M. Holburn, 01 730 2152.

Application in writing with details of experience and the names of two referees to: Mis K Lomas, Blood Group Reference Laboratory, Gatliff Road, off Ebury Bridge Road, London SW1W 8QJ.

3440(A)

HEAD OF PHARMACOLOGY DEPARTMENT

A leading Spanish Pharmaceutical Company situated in the mediterranean city of Barcelona invites applications from pharmacologists for the above post in a Pharmacology Department. The man we appoint will have a good honours degree in an appropriate discipline, a PhD in pharmacology and several years post-doctoral experience preferably in the pharmaceutical industry.

The successful applicant will be responsible to the director of Biological Sciences and must be able to formulate and organise research and development projects and collaborate with the other departments in the Biological and Chemical science groups.

Knowledge of Spanish is not initially essential but the successful candidate must be prepared to acquire adequate fluency in this language within 2 years. The salary is of US$40,000 pa, tax free and special assistance will be given for removal expenses to Barcelona.

Applications in writing with full curriculum vitae should be addressed to:

Pharmacology Department
P.O.B. 1583
BARCELONA-24 (Spain)

THE INSTITUTE OF LARYNGOLOGY AND OTOLOGY

330/332 Gray's Inn Road
London WC1X 8EE

Applications are invited for the post of

GRADUATE RESEARCH ASSISTANT

DEPARTMENT OF AUDIOLOGY

The successful applicant will be engaged in the measurement of hearing and balance in controlled clinical trials on patients suffering from vertigo. These studies will be conducted in the associated Royal National Throat, Nose and Ear Hospital. He/she will also be expected to liaise with general practitioners who will be involved in the study.

Applications in writing, giving qualifications, experience, and the names of two referees, should be sent to Professor R Hinchcliffe at the Institute. 3525(A)

UNIVERSITY OF LIVERPOOL

ENVIRONMENTAL ADVISORY UNIT

Applications are invited for the post of

ADVISORY OFFICER

in the Environmental Advisory Unit, Department of Botany. The Unit provides an advisory service and applied research facilities for Local Authorities and Industry on a wide range of environmental/ecological problems. Major projects centre on the reclamation of derelict and contaminated land, air pollution and environmental impact studies.

Applicants should have a good degree in Biological Sciences and a minimum of three years post-graduate research experience related to solving environmental problems. Preference will be given to candidates holding a PhD. A clean driving licence is essential: a generous car user's allowance will be given.

The post is tenable initially for one year, renewable annually subject to satisfactory progress.

Salary range £3,775 to £5,488 per annum depending on age and experience.

Applications, together with the names of three referees, should be received not later than 9th November, 1979, by The Registrar, The University, P.O. Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/816/N 3510(A)

RESEARCH TECHNICIAN for the Department of Physiology either at trainee level or qualified. The successful candidate will be involved in neurological work and will be encouraged to take an active interest in the research programme. Experience with histological or pharmacological techniques an advantage but not essential. Applicants at trainee level should have a minimum of four 'O' levels, including science subjects and those for a higher grade relevant qualification up to ONC in Medical Laboratory Sciences or equivalent. Salary scale £1,834 to £2,553 p.a. (trainee) £3,122 to £3,553 p.a. (qualified). Ref. 429/C/343. Application form from, Assistant Secretary, Personnel Office, University of Birmingham, PO Box 363, Birmingham B15 2TT. 3489(A)

INTERNATIONAL CROPS RESEARCH INSTITUTE FOR THE SEMI-ARID TROPICS (ICRISAT)

needs the following personnel, all to be based at headquarters near Hyderabad, India, unless otherwise indicated:

PROGRAM LEADER, FARMING SYSTEMS RESEARCH

The appointee will be required to provide administrative and scientific leadership to a multidisciplinary team of about 30 scientists and supporting staff in developing farming systems that will increase and stabilize agricultural production in the seasonally dry semi-arid tropics. Must be able to understand, conceptualize and articulate an holistic approach to agriculture and to research in farming systems. Qualifications: Doctorate with excellent academic record in agronomy, soil science, agricultural economics or agricultural engineering. At least 10 years experience in field research with some experience in developing countries. Good theoretical background, a demonstrated scientific ability through formal publications and significant administrative experience are desirable qualifications.

SOIL AND WATER SCIENTIST

The appointee will work with the Associate Director, Cooperative Programs in liaison with ICRISAT programs in Africa and elsewhere and assist in preparation and writing of research projects, project funding proposals and reports. The post will involve regular overseas travel and will include assessment of ongoing programs. Qualifications: Doctorate with an excellent academic record in soil and water engineering, soil science, or agricultural engineering, substantial formal training in hydrology; proven ability for team work with other scientists in interdisciplinary research programs. Experience in agricultural research pertaining to less developed countries of the semi-arid tropics, at least ten years post-doctoral research experience, and an ability to speak and write French would be advantageous.

SOIL PHYSICIST

Responsible within a multidisciplinary, farming systems research program for developing and conducting research to investigate major soil physical factors that limit crop production and resource use in the semi-arid tropics and develop methods suitable for their alleviation by farmers of limited means. Qualifications: Doctorate in soil physics or associated sciences or equivalent. Ten years experience in both theoretical and applied soil physical research. Ability to lead a team of scientists and to collaborate in interdisciplinary research. Experience in tropical or arid envrionments would be an advantage.

CROP PHYSIOLOGISTS

One each for groundnut and pulses (pigeonpea and chickpea), to plan and conduct physiological research in cooperation with a multi-disciplinary team of international scientists. Research will be problem-solving and field oriented, but requires knowledge of modern laboratory techniques. Qualifications: A doctorate with excellent academic record; demonstrated scientific ability through formal publications and relevant work experience after post-graduation.

PLANT VIROLOGIST

Responsible for planning and conducting research, in cooperation with an interdisciplinary team of scientists, on virus diseases of ICRISAT crops, (Sorghum, Pearl Millet, Chickpea, Pigeonpea, Groundnut), with special reference to groundnuts. Qualifications: Doctorate in Plant Pathology with ten years research experience in plant virology, preferably in legumes, as evidenced by publication/reports. Experience in electronmicroscopy and serological techniques would be a definite advantage.

PLANT BREEDER, GROUNDNUT

(To be based in Africa)

Responsible for planning and conducting research, in cooperation with a team of international scientists, to develop advance breeding materials for national and regional programs. Qualifications: Doctorate in Plant Breeding with five years research experience in plant breeding, preferably in groundnut, as evidenced by publications/reports. Experience in the semi-arid tropics and bilingual ability in English and French would be an advantage.

TRAINING OFFICER

Responsible for assisting in development of practically oriented training program and instruction related to SAT crop improvement and natural resource utilization, with emphasis on communication in both French and English. Qualifications: Doctorate or equivalent in genetics, plant breeding, soil science, or agronomy with experience in teaching; French as first language or demonstrated ability to speak and write fluently in French; proven ability for team work with other scientists in interdisciplinary research and training programs. Ten years' post-doctoral research experience, and experience in agricultural training and research pertaining to less developed countries of the SAT would be an advantage.

Salaries for all of above positions commensurate with qualifications and experience; excellent fringe benefits.

Send resume by December 15, 1979 to: Director, ICRISAT, ICRISAT Patancheru P.O., Andhra Pradesh, 502 324, India. W4545(A)

NATURAL ENVIRONMENT RESEARCH COUNCIL
INSTITUTE OF OCEANOGRAPHIC SCIENCES

Oceanographic Research in connection with the possible disposal of High Level Radioactive waste in the Deep Ocean

The Department of the Environment has commissioned NERC to carry out a substantial programme of research in connection with the Government's decision to explore oceanic disposal options for high level radioactive waste.

The work will be carried out by the Institute of Oceanographic Sciences and will be based at its Wormley, Surrey, Laboratory. It will consist of long term projects in many of the disciplines of oceanographic research. The projects will be supervised by the senior staff of the Institute and will be run in parallel with the present research programme.

Applications are invited for thirteen posts for scientists and specialists and specialist support staff. It is expected that most of them will be filled at the SO/HSO level by people who have recently achieved graduate or postgraduate qualifications, though there is some flexibility for appointment at a higher level for posts where substantial experience is particularly valuable.

The posts to be filled are: –

1. **GEOLOGIST/GEOPHYSICIST** – to work on the selection and survey of areas to be studied and on the evaluation of potential disposal sites.
2. **MARINE SEDIMENTOLOGIST/STRATIGRAPHER** – to work on the stability of sediments in the deep marine environment.
3. **GEOPHYSICIST/ENGINEER** – to measure the physical properties of deep-sea sediments both *in situ* and in the laboratory.
4. **GEOLOGIST** – to investigate the distribution of ice rafted rock debris in the North Atlantic over the past million years.
5. **GEOPHYSICIST** – to study the three-dimensional transport of heat within deep-sea sediments by conduction and convection of pore waters.
6. **GEOCHEMIST/GEOLOGIST** – to investigate the diagenesis and chemical and mineralogical composition of pelagic marine sediments from different oceanic areas.
7. **BIOLOGIST** – to join the team working on various aspects of deep sea benthic biology.
8. **ELECTRONIC/ACOUSTIC ENGINEER** – to support work on underwater acoustics, transponder navigation and float tracking, telemetry from and control of bottom instrumentation.
9. **DESIGN ENGINEER/HYDRO DYNAMICIST** – to assist senior designers in the Ocean Engineering Group on work arising from the Deep Sea Radioactive Waste Disposal Programme.
10. **GEOCHEMIST** – to undertake day to day responsibility for research into the composition of interstitial waters of pelagic marine sediments in order to elucidate the physico-chemical processes which determine this composition.
11. **PHYSICIST** – to take a leading part in an experimental study of the benthic boundary layer.
12. **COMPUTATIONAL PHYSICIST** – to develop numeric models of the water movements within the benthic boundary layer.
13. **A SCIENTIST** – to assist with scientific administration in IOS in connection with commissioned research.

Salary scales are as follows:

	Present Rates	*From 1 January 1980*
Scientific Officer	£3289 – £5085 p.a.	£3591 – £5486 p.a.
Higher Scientific Officer	£4727 – £6211 p.a.	£5097 – £6737 p.a.
Senior Scientific Officer	£5876 – £7864 p.a.	£6332 – £8705 p.a.

Starting salary may be above the minimum, according to qualifications and experience.

The Natural Environment Research Council is not a government department, but conditions of service are similar to those of the Civil Service and there is a non-contributory pension scheme.

Application forms are available from The Secretary, Institute of Oceanographic Sciences, Wormley, Godalming, Surrey GU8 5UB, tel. Wormley (042 879) 4141 extn 272. Please quote the numbers of the post(s) for which you would like to apply.

Closing date: 2 November 1979. 3480(A)

THE POLYTECHNIC OF CENTRAL LONDON

SCIENCE DIVISION

TECHNICIAN GRADE 4 (Two Posts)

Salary:- £3,747 to £4,233 inclusive of London Allowance

1. Animal House

An experienced person required to see to the daily requirements of an animal house dealing with small mammals, duties include cleaning and sterilising of equipment and rooms, feeding and care of animals, arranging breeding programmes and ensuring home office regulations are implemented.

2. Chemistry Section

To join a team of Technicians working in teaching and research laboratories, knowledge of chemical and biochemical techniques would be an advantage. Person appointed would be expected to prepare materials for practicals including preparing solutions and providing assistance to staff and students.

Qualifications and experience for both posts C&G Part I, ONC, OND or 2 'A' Levels with 7-9 years experience.

Application form and job description from the Establishment Officer, PCL, 309 Regent Street, London W1R 8AL (Tel. 01-580-2020 ext.212). 3502(A)

SHEFFIELD AREA HEALTH AUTHORITY (TEACHING)

CENTRE FOR HUMAN GENETICS

CYTOGENETICIST

There is an immediate vacancy for a Cytogeneticist (Basic Grade) at the above unit. The work is part of a Regional diagnostic service and will include tissue culture and the identification of chromosome abnormalities. Applicants should have a relevant Science degree.

Salary scale £3,486 rising to a maximum of £5,592. For further information telephone Sheffield (0742) 667333.

Applications giving details of age, qualifications and experience, with the names and addresses of two referees to: The District Personnel Officer, Floor B, Hallamshire Hospital, Glossop Road, Sheffield S10 2JF. 3507(A)

UNIVERSITY OF OXFORD

RESEARCH OFFICERSHIPS IN NUCLEAR PHYSICS

The University proposes to appoint two Research Officers in the Department of Nuclear Physics, in the field of experimental nuclear structure physics, for a period of three years, from 1 April 1980 or earlier if possible. Salary according to age on the University Lecturer scale (under review) £4,333 to £9,581. Further particulars may be obtained from the department.

Applications (one typed copy) including a statement of qualifications, publications and the names of two referees, should reach Professor K.W. Allen, Department of Nuclear Physics, Keble Road, Oxford OX1 3RH by 30 November 1979. 3488(A)

THE UNIVERSITY OF HULL

DEPARTMENT OF BIOCHEMISTRY

A vacancy exists on the established staff for

A SENIOR RESEARCH TECHNICIAN

Grade 5

The post is connected with the Departmental Chemostat and Fermenter Suite and the duties will be mainly concerned with research into the synthesis of lipid substances in Microorganisms. Minimum qualifications: HNC or equivalent, plus 8-9 years experience in Biochemistry. Additional experience in Microbiology, particularly in fermentation techniques, would be advantageous. Salary on the scale £3,700 to £4,320 per annum. Applicants with less experience will be considered, to commence initially on a lower grade. Ref. No. TBCH/5.

Applications giving details of age, qualifications and experience should reach the Technical Staff Officer, University of Hull, HU6 7RX by 31 October quoting the names of two referees. 3483(A)

CITY OF LONDON POLYTECHNIC

DEPARTMENT OF BIOLOGICAL SCIENCES

GRADUATE RESEARCH ASSISTANT

A graduate research assistant is required immediately to work on an Agricultural Research Council sponsored study of plant substances affecting calcium metabolism. The project will be of interest to biochemists/physiologists/pharmacologists. The successful applicant will be encouraged to register for a higher degree.

Salary: £3,321 to £3,417 to £3,513.

A full curriculum vitae giving the names and addresses of two referees should be sent to Dr. K.M.L. Morris, Department of Biological Sciences, Old Castle Street, London E1 7NT, within two weeks of the appearance of this advertisement. 3484(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF SURGERY

Applications are invited for the post of post-doctoral University Research Assistant/Senior Research Assistant in the Department of Surgery, to become the scientific member of a clinical team investigating clinical, physiological and biochemical aspects of liver disease, particularly portal hypertension and oesophageal varices.

The appointment will be tenable for one year in the first instance and may be renewed though not normally more than twice. The initial salary will be within the range £3,775 to £5,488 per annum according to qualifications and experience.

Arrangements to visit the Department may be made with Professor R. Shields and Mr I Taylor, telephone 051-709 0141 ext 2676 and 2677 or 051-708 0020.

Applications, together with the names of two referees, should be received not later than 12th November, 1979, by the Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote ref RV/806/N. 3494(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF ORTHOPAEDIC AND ACCIDENT SURGERY

TECHNICIAN (Grade 5)

Duties include responsibility for histological preparations and autoradiographs of bone, cartilage and connective tissues for the research and teaching programme into arthritis, fracture repair and bone cancer. Previous experience of photographic techniques an advantage.

Salary in a range £3,700 to £4,320 p.a. (under review) according to qualifications and experience.

Application forms may be obtained from the Registrar, The University P.O. Box 147, Liverpool L69 3BX. Quote Ref: RV/815/N 3509(A)

SEDIMENTOLOGIST/Stratigrapher, Assistant or Associate Professor of Geology, tenure-leading, August, 1980. Requires PhD plus demonstrated research abilities. Salary minimum $15,000. Duties include teaching sedimentology, lithostatigraphy and introductory courses. Direct graduate research. Preference will be given to applicants in the field of terrigenous clastic sedimentology who will be able to interact with current faculty in clastics, paleontology and groundwater geology. Apply by January 15 with resume, transcripts and names of three references to: Chairman, Department of Geology, 433 Morrill Hall, The University of Nebraska-Lincoln, Lincoln, Nebraska 68588. May also secure additional information about position from this address or by telephoning (402) 472-2663. Affirmative Action/Equal Opportunity Employer. W448(A)

THE UNIVERSITY OF MANCHESTER

DEPARTMENT OF ANATOMY

RESEARCH TECHNICIAN (Grade 5)

Applications are invited for the post of research technician to work in the area of experimental neurology. Applicants must hold HNC or equivalent and have at least 8 years' laboratory experience. Competence in a wide range of modern techniques in histology and microscopy including autoradiography is essential. Previous experience in research work is required and a working knowledge of the use of neuroanatomical, neurophysiological or neuropharmacological research techniques would be a considerable advantage.

Salary scale £3,700 to £4,320 pa together with further comparability payments and subject to overall review as from 1st October 1979.

Applications giving details of age, qualifications, experience and the names of two referees should be sent to Professor P.F. Harris, Department of Anatomy, Medical School, University of Manchester, Manchester M13 9PT. 3506(A)

ASSISTANTSHIPS

UNIVERSITY OF LEICESTER

DEPARTMENT OF BOTANY

Postdoctoral/postgraduate research assistantship in secondary product production by plant tissue cultures

Two posts are available for research on the above project to be held either at postdoctoral or postgraduate research assistant level. In the case of a successful applicant's being appointed at the post-doctoral level the appointment will be for two years only. In the case of a candidate's being appointed at postgraduate level funds will be available for three years and registration for higher degrees will be possible.

Further information on the project and related conditions may be obtained from Professor H. Smith, Botany department, University of Leicester, Leicester LE1 7RH. 3432(P)

UNIVERSITY OF DURHAM

GLYCOPROTEIN RESEARCH UNIT

Applications are invited for a

SENIOR RESEARCH ASSISTANTSHIP

tenable for one to two years, and for a

RESEARCH ASSISTANTSHIP

tenable for one year, in the Glycoprotein Research Unit. The work involved will be studies on the control mechanisms of biosynthesis and secretion of glycoproteins by human fibroblasts *in culture* and by chicken trachea *in vitro* with some emphasis on the role of calcium-binding proteins. It is expected that the candidate for the senior post should have experience at doctoral level in cell-culture and membrane fractionation techniques. Knowledge of isotopic-labelling and chromatographic separation methods will be essential for both posts. Initial salary for the Senior Research Assistant will be in the range of £4,333 to £5,199 p.a. and for the Research Assistant £3,775 to £4,333 p.a. plus superannuation.

Applications, including curriculum vitae and names of three referees should be sent by 31st October 1979 to the Registrar, Science Laboratories, South Road, Durham, DH1 3LE. For further information contact Dr P W Kent or Dr N Mian at Durham 64971, ext 239.

3527(P)

UNIVERSITY OF GLASGOW

DEPARTMENT OF CELL BIOLOGY

POST-DOCTORAL RESEARCH ASSISTANT

Applications are invited for a

RESEARCH ASSISTANTSHIP

funded by the M.R.C., to study the membrane properties of mononuclear phagocytes as related to their behaviour. The person appointed would work with a small group interested in the cellular aspects of inflammation; a background in cellular immonology or cell biology would be advantageous. The appointment is for a maximum of three years, starting as soon as possible, and would be on salary range 1A for Research and Analogous Staff (£4,333 to £5,777). Appropriate superannuation scheme will apply.

Applications, enclosing a curriculum vitae and the names of two referees, should be sent to Dr J.M. Lackie, Department of Cell Biology, University of Glasgow, Glasgow, G12 8QQ.

In reply please quote Ref. No. 4506/1M.

3511(P)

FELLOWSHIPS

UNIVERSITY COLLEGE DUBLIN

FACULTY OF AGRICULTURE

POST-DOCTORAL FELLOWSHIP

Applications are invited for a post-doctoral fellowship (sponsored by the National Board for Science and Technology) to study the micromorphology of structurally-damaged and unstable topsoils in Ireland.

Candidates must have considerable experience in soil micromorphology; competence in soil physical measurements is also desirable. The initial appointment is for one year with the probability of renewal for a further two years. The salary scale is approximately £4,200 to £4,800.

Applications, with details of qualifications and experience, to:

Dr J.F. Collins, Department of Agricultural Chemistry and Soil Science, Agriculture Building, Belfield, Dublin 4.

3516(E)

-Unique Opportunity-

STANFORD UNIVERSITY

NSF POSTDOCTORAL FELLOWSHIP in MOLECULAR BIOLOGY and COMPUTER SCIENCE

$14,000 per annum

Applicants should be familiar with the techniques of modern molecular biology and be interested in entering the field of computer science. Previous programming experience is useful but not essential. Responsibilities will include development and maintenance of a knowledge base of current laboratory techniques for use with an advanced model of automated experimental planning. One goal of this program is to train an individual for a career in computer science as applied to molecular biology and genetics. While the fellowship will be awarded through the Department of Computer Science, the fellow will interact regularly with research groups in the Departments of Biochemistry and Medicine.

Send resume and the names of three references to either:

Dr Douglas Brutlag, Department of Biochemistry or Dr L.H. Kedes, Department of Medicine, Stanford University, School of Medicine, Stanford, California 94305. Equal opportunity through affirmative action. W383(E)

POST-DOCTORAL FELLOW

Laboratory with active program in the study of hormone receptor/antibody interactions has an opening for an individual holding a PhD degree and with experience in hormone receptor separation and purification. Although funds for the position at the M.R.C. Canada Postdoctoral Fellowship rate are available, the successful candidate would be encouraged and assisted in applications for his/her own Fellowship support.

Applications should include curriculum vitae and previous research experience. The applicant should request three referees to send letters of support to: Dr. N.R. Farid, Faculty of Medicine, Health Sciences Centre, 300 Prince Phillip Drive, St John's, Newfoundland A1B 3V6. W441(E)

GIRTON COLLEGE CAMBRIDGE

Applications are invited for a scientific research fellowship open to graduates of any university and tenable for three years from 1st October 1980. The applications should be in the field of Mathematics, Natural Sciences, Geography and allied subjects.

The fellowship is to the value of £3,000 per annum to a candidate with a PhD and £2,750 per annum to a candidate who has not completed a PhD. The fellowship is pensionable under U.S.S.

Particulars are available from the Secretary to the Council, Girton College, Cambridge CB3 0JG to whom applications should be sent by 19th November, 1979.

3503(E)

NEWNHAM COLLEGE CAMBRIDGE

RESEARCH FELLOWSHIPS

The College, acting as part of a Group, invites applications from women for one or more Research Fellowships which will normally be tenable from 1st October 1980.

Further details, together with application forms (which must be completed and returned not later than 20th October 1979) may be obtained from the Secretary, C.I.A.O., Kellet Lodge, Tennis Court Road, Cambridge CB2 1QJ.

3528(E)

THE BRITISH COUNCIL

Academic visits to the Soviet Union, Czechoslovakia, Hungary, Romania, Bulgaria and German Democratic Republic

Applications are invited from British academic staff in all disciplines for short (two week) and medium term (1-6 months) visits, under agreed exchange programmes, to the above countries. Short visits normally involve a tour of a number of institutions appropriate to the visitor's subject area. Medium term visits are intended to facilitate research and are usually based at one establishment.

For details and application forms please write or telephone to: Higher Education and Science Department, The British Council, 10 Spring Gardens, London SW1A 2BN. Tel: 01-930 8466 ext: 2683.

Closing dates for completed applications is 10 November 1979.

Please quote 79/E2 when responding to this advertisement. 3531(E)

QUEEN MARY COLLEGE

University of London

PLANT BIOLOGY AND MICROBIOLOGY DEPARTMENT

Applications are invited for a Postdoctoral Research Fellowship sponsored by SRC Marine Technology Directorate for work on distribution and activity of Sulphate-Reducing Bacteria in North Sea sediments related to anoxic corrosion of mild steel. Experience of working with anaerobic bacteria an advantage. Appointment for 1 year in first instance, starting not later than January 1980.

Initial salary in range (under review) £5,073 to £5,650 p.a. (including London Allowance). Applications, including curriculum vitae and names of 2 referees, should be sent as soon as possible to The Secretary, Queen Mary College, Mile End Road, London E1 4NS. 3499(E)

STUDENTSHIPS

THE OPEN UNIVERSITY

SRC Case Studentship in Chemistry

Applications are invited for a Case Studentship, tenable from a mutually agreed date prior to 1st March 1980 and leading to the degree of PhD.

The project involves the development of synthetic routes to certain types of organic heterocylic compound that are of interest for their anti-inflammatory or anti-hypertensive activity. The syntheses are centred around a photochemical step, and there is scope for studying the mechanism of these photoreactions.

The supervisors are Dr John Coyle of the Open University and Dr Keith Godfrey of Reckitt and Colman (Pharmaceutical Division).

Candidates should possess, or expect to obtain, a good honours degree or its equivalent in either Chemistry or Combined Science with Chemistry as a major subject. Applications giving a full curriculum vitae and the names and addresses of two academic referees should be sent as soon as possible to *Dr J.D. Coyle, The Open University, Walton Hall, Milton Keynes, MK7 6AA* from whom further particulars can be obtained.

Please quote reference (CC/1). Initial enquiries may be made by telephone to Dr Coyle (Milton Keynes 653483). 3490(F)

UNIVERSITY OF OTAGO
Dunedin, New Zealand
NZERDC STUDENTSHIP

Applications are invited from persons with a good honours degree in Geology for work leading to a PhD on the tertiary sedimentary rocks of the Waiau Basin, a fault controlled basin at the southern end of the Alpine transform fault.

The project will involve preparation of a basin analysis with particular attention to hydrocarbon potential, and applicants should be able to perform field work in rugged terrain.

Further details and application forms may be obtained from the joint supervisor of the project Dr R M Carter or Mr R J Norris, University of Otago, Geology Department, PO Box 56, Dunedin, New Zealand. 3521(F)

UNIVERSITY COLLEGE OF SWANSEA

Case Research Studentship

Applications are invited from candidates with an interest in Organic Chemistry and with a good honours degree or equivalent for an S.R.C. **CASE Research Studentship** in the **Department of Chemistry.**

The award is for the study of the synthesis of novel macrocyclic lactones with potential central nervous system activity and will be in collaboration with Pfizer Ltd.

Letters of application, which should include the names and addresses of two referees, should be sent to Dr K Smith, Department of Chemistry, University College of Swansea, Singleton Park, Swansea, SA2 8PP, ***as soon as possible.*** 3535(F)

UNIVERSITY OF SOUTHAMPTON
RESEARCH IN CRYOGENICS
Superconducting AC Generators

Applications are invited for an
S.R.C. CASE Studentship

on "Refrigeration cycles for rotating helium at 3000 rpm". The successful candidate will be expected to register for a higher degree.

Applicants with a good degree in Science or Engineering should write to Dr R.G. Scurlock, Cryogenics Group, University of Southampton, S09 5NH. Please quote reference N. 3530(F)

THE OPEN UNIVERSITY

Research Studentship(s) in Biology/Brain Research

Studentships, leading to a PhD, available immediately to work with:

(1) Professor Steven Rose on environmental, nutritional and hormonal factors influencing developmental biochemistry of the brain.

(2) Dr Rob Random on developmental genetics of drosophila.

Candidates should preferably have 1st or 2(i) degrees in i) biochemistry or neurobiology (ii) genetics.

For further particulars, etc., telephone Professor Rose or Dr. Ransom on (0908) 653225 or (0908) 653464 as soon as possible. Please quote reference BR2. 3491(F)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY

Applications are invited from holders of good honours degrees in Biochemistry, Pharmacology or Psysiology for a Duphar Research Studentship to study the mechanism of action of cerebral activating drugs. The terms and conditions of the award are equivalent to Research Council awards, and will include registration for a higher degree. The successful applicant will be required to start work as soon as possible.

Further details may be obtained from Dr N.M. Horn, Department of Physiology and Pharmacology, Medical and Biological Sciences Building, Bassett Crescent, East, Southampton, SO9 3TU, to whom applications including the names and addresses of two academic referees should be sent. Please quote reference N. 3493(F)

UNIVERSITY OF BIRMINGHAM
CASE Studentship
The Physical ageing of PVC and copolymers

Applications are now invited from suitably qualified Chemists, Physicists or Material Scientists for a three year SRC (CASE) Research Studentship in the Department of Chemistry. In collaboration with BP Chemicals Ltd, the programme will involve assessing the effect of physical ageing and morphology in the mechanical properties of PVC.

Applications, together with the names and addresses of two referees, should be sent to: Professor J.C. Tatlow, Department of Chemistry, University of Birmingham, PO Box 363, Birmingham, B15 2TT. 3486(F)

FOR SALE and WANTED

"FROM MASSLESS to Material Universe" by M.E. Winfield. Written in language understandable by scientists of all disciplines, the book presents a new outlook on the foundations of physics. It argues for the evolution of matter from particles simpler than any yet known, and offers suggestions as to the nature of the particles. The evolutionary hypothesis provides for the existence of fields more subtle than the electromagnetic and gravitational, and will therefore be of interest to scientists attempting to explain the Kirlian effect and related phenomena. Price $6.50 Australian. Available by mail order from Golden Point Press, Box 373, Lakes Entrance, Victoria 3909, Australia. W443(L)

CONFERENCES

NATO ADVANCED STUDY INSTITUTE
"ACTIVE DEFENCE MECHANISMS IN PLANTS"

This meeting will be held at Cape Sounion, south of Athens, Greece 21 April to 1 May 1980. It will be based on *c.* 15 lectures by well known authorities, papers and discussions on the active mechanisms by which higher plants prevent infection and colonization by microorganisms, viruses and related agents.

Attendance will be by invitation. Part of travel and hotel expenses may be met for participants from NATO countries who cannot be wholly supported from other sources. There will be a few places but no expenses for scientists from other than NATO countries.

Applications to attend should be sent as soon as possible to Professor R K S Wood, Botany Department, Imperial College, London SW7, UK, stating age, title of paper to be submitted, contribution to be made towards expenses of attendance. 3519(C)

Gordon Research Conferences

"Frontiers of Science"

1980 Winter Schedule, Miramar Hotel, Santa Barbara, California

January 7-11	Liquid Crystals	Sensory Transduction in Microorganisms
January 14-18	Polymers	Orientational Disorder in Crystals
January 21-25	Thin Organic Films and Solid Surfaces	Deformation Mechanisms in Polymers and Composites
January 28-February 1	Electrochemistry	Chemical Oceanography
February 4-8	Chemistry and Biology of Peptides	Physico-Chemical Aspects of Photosynthesis
February 11-15	Chemical Aspects of Plant-Herbivore Interaction	
February 18-22	Immunochemistry and Immunobiology	
February 25-29	Metals in Biology	Structural Macromolecules: Collagen

Conference Fees:

Conferee (registration, room, meals)	$215.00
Guest (room, meals)	$165.00

Program: The complete program will be published in the October 19, 1979 issue of *Science*.

Requests for applications or for additional information should be addressed to:

Dr Alexander M. Cruickshank, Director
Gordon Research Conferences
Pastore Chemical Laboratory
University of Rhode Island
Kingston, RI 02881, U.S.A.

W453(C)

An international conference on

Safety Evaluation of Nitrosatable Drugs and Chemicals

to be held at
The Royal College of Physicians, London, England
on
24th and 25th January 1980

To assess the extent of human risk from the nitrosation of drugs and chemicals in vivo. *To evaluate the methodology available for the safety evaluation of nitrosatable chemicals.*

Under the auspices of
The University of Surrey and Pharmaceutical Industry

Conference limited to 300 participants

For further particulars:
Dr. C. Ioannides,
Department of Biochemistry,
University of Surrey,
GUILDFORD,

Our new Lysate is out on its own–but is backed by 80 labelled amino-acids

With Amersham's new reticulocyte lysate you just add the labelled amino-acid of your choice and mRNA and incubate. The lysate has been nuclease treated* to remove endogenous mRNA and has been optimised for immediate and convenient use. Each batch is tested for high protein synthesis activity with low background and is available from stock.

Our new lysate is backed by a comprehensive range of about 80 amino-acids labelled with ^{3}H, ^{35}S and ^{14}C, including our very widely used L-[^{35}S]methionine. All are produced to the same high standards of purity.

On its own our new lysate gives you quality, convenience and flexibility.

Together with our range of labelled amino-acids it gives you a complete, high quality translation package you can rely on for protein synthesis.

* based on the method of Pelham, H.R.B. and Jackson, R.S. *Eur. J. Biochem.*, **67,** 247-257, 1976.

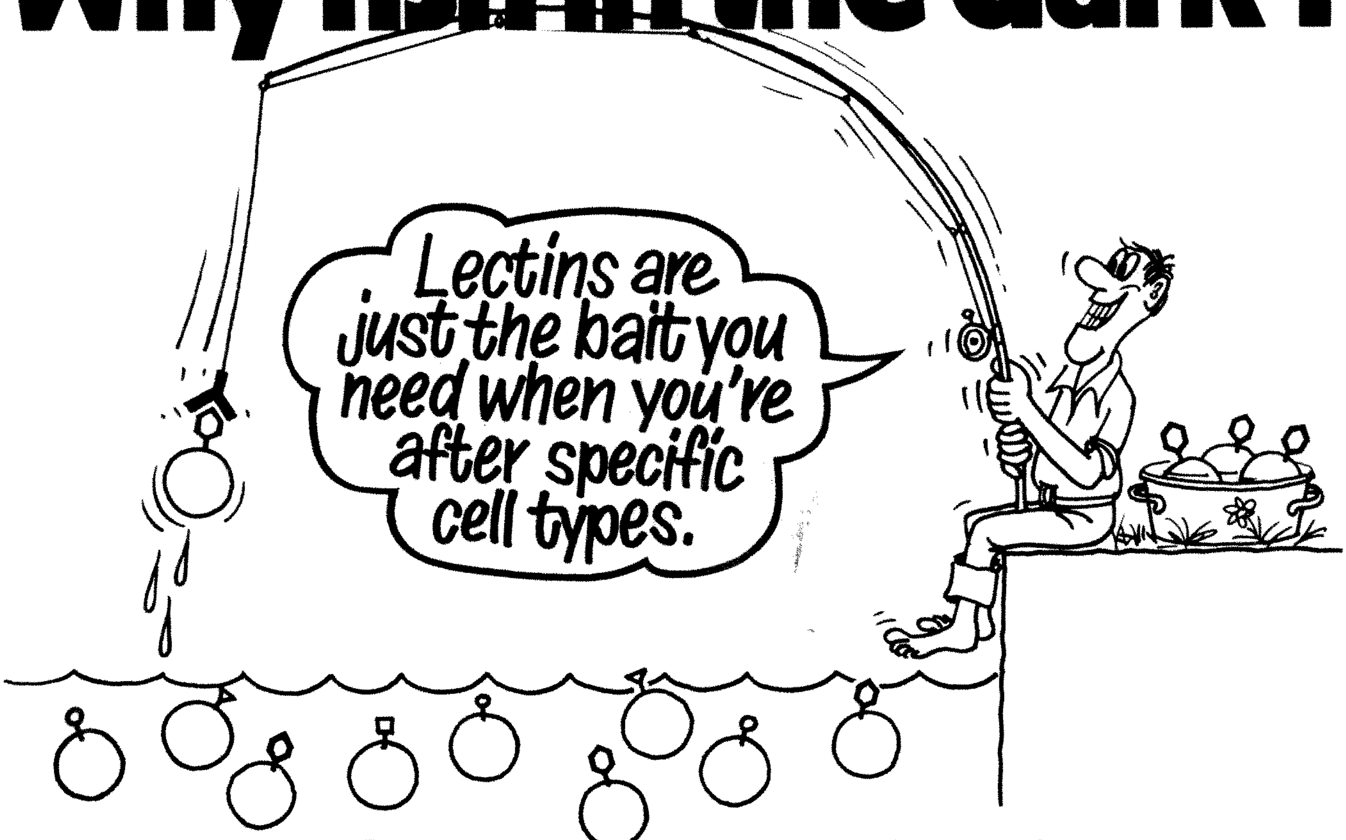
Why fish in the dark?



Lectins are just the bait you need when you're after specific cell types.

Boehringer Mannheim offers the following lectins:

Lectin	Source	Sugar Specificity	Cat. No.
Lectin from U. europaeus (UEA)	Ulex europaeus	α-L-Fuc	373222
Ricin	Ricinus communis	β-D-Gal>α-D-Gal>D-GalNAc	223743
Lectin from R. communis (RCA 120)	Ricinus communis	β-D-Gal> α-D-Gal	223727
Lectin from peanuts (PNA)	Arachis hypogea	β-D-Gal-(1→3)-D-GalNAc> D-GalNH$_2$ = α-D-Gal	223697
Lectin from soybeans (SBA)	Glycine max	α-D-GalNAc> β-D-GalNAc>> α-D-Gal	373206
Lectin from H. pomatia (HPA)	Helix pomatia	α-D-GalNAc> α-D-GlcNAc>> α-D-Gal	373168
Lectin from wheat germs (WGA)	Triticum vulgaris	β-D-GlcNAc-(1→4)-β-D-GlcNAc-(1→4)-GlcNAc> β-D-GlcNAc-(1→4)-β-D-GlcNAc	166006
Concanavalin A (Con A)	Canavalia ensiformis	α-D-Man> α-D-Glc>α-D-GlcNAc	103594
Lectin from lentils (LA)	Lens culinaris	α-D-Man> α-D-Glc> α-D-GlcNAc	165964
Lectin from P. americana (PWM)	Phytolacca americana (Pokeweed mitogen)	Di-N-acetylchitobiose (Yokoyama, K. et al. (1978) Biochim. Biophys. Acta, **538**, 384)	373184

CUT YOUR AD BUDGET LATELY?

Honesty compels us to admit that you're not alone.

Whenever the cost/price squeeze gets really tough, it's a temptation to regard advertising as a cost... and to cut.

Not at every company, however.

In recent years, a significant change has taken place in the thinking of many management men about advertising budgets. No longer are appropriations cut automatically when the pressure is on.

Why?

For a number of reasons. Among them are:

1. *With the growth of the marketing concept,* advertising is no longer looked upon merely as an expense, but as an integral part of the company's marketing mix.

2. *Firms that maintain advertising during recession years do better in sales—and profits—in those and later years.* That was proved conclusively in studies of five separate recessions made by ABP and Meldrum and Fewsmith.

3. *The cost of a salesman's call today makes it imperative to make maximum use of advertising.* The average cost of an industrial sales call soared to a record $96.79 according to the latest report by McGraw-Hill's Research Laboratory of Advertising Performance. Yet studies show that a *completed* advertising sales call—that is, one ad read thoroughly by one buying influence—literally costs only pennies. Why deny yourself such efficiency?

4. *In some cases, there is no way to reach customers except by advertising.* The "Paper Mill Study" shows (1) the number of buying influences in the average plant is far greater than marketers are aware of, (2) the vast majority of these influences are unknown to salesmen, (3) no salesman has the time to contact all influences even if he knows them.

5. *Selling costs are lower in companies that assign advertising a larger role in marketing products.* So advertising is an investment in profit, just like a machine that cuts production costs.

6. *Memories are short.* There is an estimated 30% turnover every year among buyers. It isn't surprising, then, that lack of advertising contact can quickly result in loss of share of market.

7. *Most down periods turn out to be shorter than expected.* The history of every postwar recession is that it didn't last as long as predicted. Why gamble your market position for short-term gain?

8. *Consider lead time.* Very few products sold to business and industry are bought on impulse. The advertising you are doing—or missing—right now will have its effect years from now.

9. *Advertising works cumulatively.* It would be nice to think that every reader reads all of your ad. We know it doesn't work that way. To be most effective, advertising must have continuity.

10. *Did your competitor cancel his budget, too?* If not, you may be taking a big risk.

11. *Will you lose salesmen?* They know that their chance of getting an order is better if they are backed up by advertising. Can you be sure of keeping them when they learn that that support has gone?

12. *You know better.* Survey after survey of executives shows that they expect a *drop* in sales if advertising stops.

But there is need for efficiency...

whenever advertising budgets are being assembled—never more than in these inflationary times. Significantly, a recent survey shows that nearly 40% of the average budget for advertising to business and industry is invested in business publication space and preparation. That's *more than double* the next largest item.

Why? Because specialized business publications remain the most effective and efficient method of reaching target audiences in business, industry and the professions.

And we can prove it.

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or New York. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,**1 (1975) and **264,** v, 11 Nov. (1976).

Biological degradation of TCDD in rats	*H. Poiger and Ch. Schlatter*	706

Culturing cells?

Would you like a cell culture technique
which gives you higher cell yields for less effort,
less time and less money?

You should know more about microcarrier culture with

Cytodex™ 1

- High cell yields
- Much smaller working volumes
- Easy control and monitoring of cultures
- Simple harvesting of cells without centrifugation
- Saves you space, effort, time and money

One gram of Cytodex 1 gives you the same capacity
for cell growth as 7 roller bottles or 76 standard Petri dishes.

Cytodex™ 1 – the new dimension in cell culture.

Ask for more information today, and prove it for yourself.

INDEXES

Annual Indexes are available for the years 1971-1978. The years' papers are listed by both author and subject.

Prices: UK: £5.00
Rest of World US$10.00

BINDERS

Keep your copies of *Nature* protected in durable black PVC binders:

- 20 plastic retention strips mean no loose parts, wire, or complex loading systems
- title blocked in gold on spine
- panel on spine for your own references

Each binder is designed to take two volumes of *Nature*; three binders will serve for a year.

Prices (including postage):
UK £3.00 each, three for £8.00
Rest of World: US$6.00,
three for US$16.00.

To order, please send details and correct remittance to:

Nature,
Circulation Department,
Macmillan Journals Limited,
Brunel Road, Basingstoke,
Hampshire RG21 2XS, England

Cheques should be made payable to *Nature*. Payment may be made in any currency at the prevailing exchange rate.

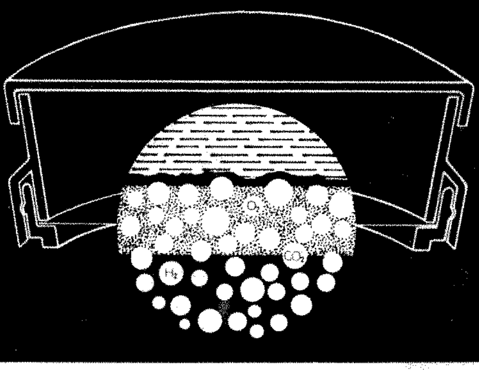
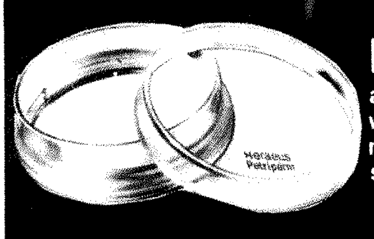
A new approach in tissue culture





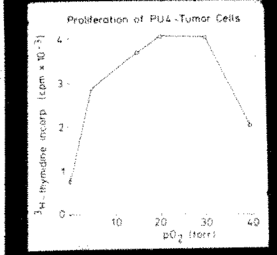
PETRIPERM

a novel culture dish with gas permeable membrane as cellular support.

Additional advantages of the PETRIPERM membrane are:

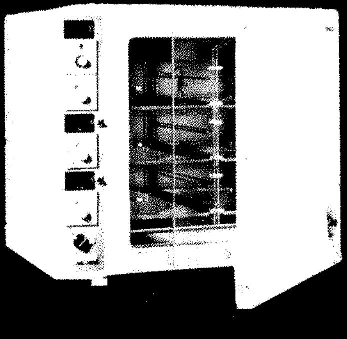
- UV permeable 200 nm
- Suitable for high power light and fluorescence microscopy
- The membrane can be cut for cell cloning, electron microscopy, staining and documentation
- Chemically resistant to acids, bases and organic solvents

PETRIPERM is available either with a hydrophilic surface for optimal attachment, or with a hydrophobic surface for easy detachment of adherent cells.



In the intact animal, the pH, and the partial pressure of both oxygen and CO_2 of the cell environment are under total biochemical and physiological control. This state is not even approximated by available techniques of monolayer cell culture in conventional tissue culture ware. Continuously changing gradients of these parameters in the micro-environment of cultured cells will obscure the biological significance of culture dependent phenomena. **PETRIPERM** is the prerequisite for the precise control of pO_2, pCO_2 and pH in the cellular environment as gases reach the cultured cells directly through the highly gas permeable 25 μm thick membrane

Heraeus—Co₂-Incubator B 5060 EK/CO₂



We build the incubator with appropriate pCO_2, pH and pO_2 control units

Spanish success story

Workers' co-ops have taken root in the Basque country; could they in Britain?

Few would disagree these days that large parts of British industry are in serious decline, and that in some cases this decline may be irreversible. Almost everything has, at one time or another, been blamed for this, but there is little doubt that one crippling aspect in many industries is the immense distrust that exists between management and the workforce. Indeed, many of those involved in the pitched battles which occupy the headlines day after day speak as if conflict is a necessary ingredient in industrial relations. Those driven to despair by arguments over the sizes of the slices being cut from a rapidly shrinking cake may be interested to know that a totally different form of industrial structure has been quietly constructed in the Basque provinces of Spain in the last twenty years; and it shows signs of considerable health. It is the workers' co-operative movement centred on Mondragon, about 450 kilometres from Bilbao.

Basque Spain is a surprisingly industralised area. There are numerous towns and villages with all manner of industry from the lightest to the heaviest, much of it blithely producing extraordinarily high levels of environmental pollution. A Basque priest, José Maria Arizmendi, came to Mondragon, an economically devastated and repressed town in the midst of this industrial area, in 1941. His first job was to try to improve secondary and technical education which was at that time minimal. As educational standards gradually rose, he and some of his first students started to ask whether they could not participate more directly in industrial enterprises than merely as employees of capitalist firms. Out of these discussions came the first workers' co-operative, ULGOR, in 1956. A manufacturer of domestic appliances, it began with 23 people; it now employs around 3,500. In the past twenty years, more than sixty co-operatives have been founded, and they employ around 15,000 people. They range from agricultural co-ops through to iron and steel foundries. The unifying feature is that no employee can join without taking a stake (of between £1,000 and £2,000) in the enterprise. Basques are traditionally savers and there is said to be no shortage of applicants.

Although management of the co-ops is ultimately in the hands of the whole work force, care is taken to give managers many of the freedoms of their cpitalist counterparts to run their co-ops imaginatively. They do not, however, have the freedom to sack employees. Salary levels for each job are publicly established, and there is only a ratio of 3:1 between the top and bottom salary rates. Those retiring from co-ops now are receiving at least £10,000 in addition to their pension.

It is not just the workers who co-operate — co-operatives themselves all work closely together. The most striking example is the communally owned bank, Caja Laboral Popular, which acts both as a conventional bank for the workers and as a very sophisticated merchant bank for the support of existing co-ops and the establishment of new ones. Other examples of so-called second-degree co-operatives include schools, a social security organisation and a research and development centre. There is no doubt that most of the co-operatives have been successful in conventinal economic terms, in addition to providing an apparently happy working environment in which there is an openness in all acitivities. Managers speak enthusiastically of the common purpose in their factories, the willingness to work all hours to get satisfied customers and the high level of productivity.

Could Mondragon-type co-operatives survive in Britain? In the past few years the handful of older co-ops in Britain, many with structures very unlike those at Mondragon, have been joined, with maximum publicity, by co-ops encouraged by Mr Tony Benn. The trouble is that they have only become co-operatives as a last, desperate resort when a capitalist venture has failed. And indeed one, the *Scottish Daily News*, soon folded. The Mondragon experience points quite unambiguously to the importance of local workers coming together, probably on a small scale to start with, with their own ideas for something entirely new. □

- Two valuable books on worker co-ops are: *Worker-Owners* (Anglo-German Foundation, St Stephen's House, Victoria Embankment, London SW1; £2.90) and *The Case for Workers' Co-ops*, by Robert Oakeshott (Routledge & Kegan Paul; £7.95).

Shuttle problems delay next planetary mission

David Dickson reports from Washington on why Jupiter must wait

The US National Aeronautics and Space Administration announced last week that it intends to delay the launch of Project Galileo — a two-vehicle mission to the planet Jupiter — from 1982 to 1984 because of problems in the development of the space shuttle.

The two-year delay will also mean separate launches for the two vehicles, one of which will orbit the planet, and the other descend into its atmosphere; initially plans were to use a single launch, but the delay means that the spacecraft will no longer be able to make use of extra push given by the planet Mars.

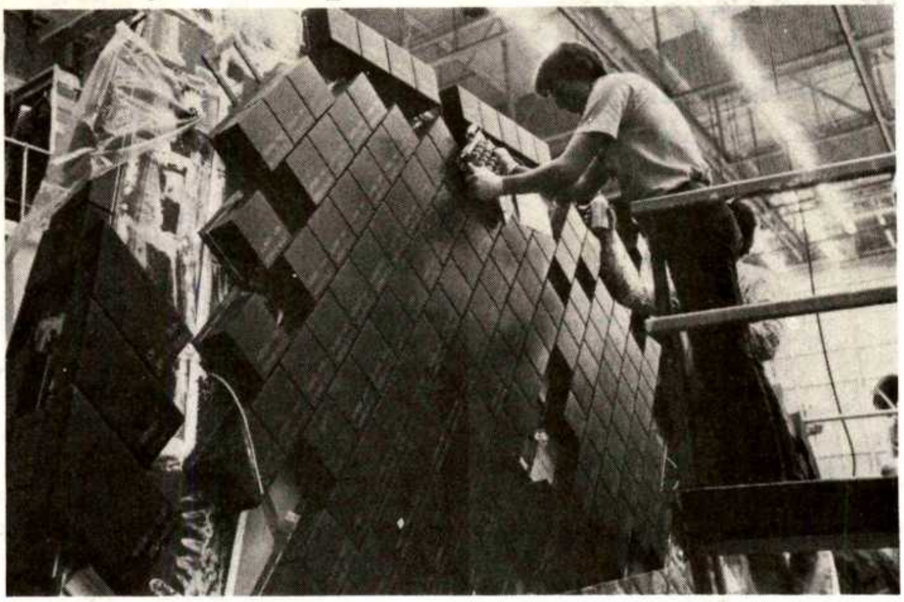
Dr Thomas Mutch, associate administrator for space science, told a House subcommittee in Washington last week that the agency had studied the implications of delays in developing the shuttle engines and decided that the risks involved in meeting the necessary schedules for both the shuttle and the inertial upper stage from which Galileo will be launched were "unacceptable". "The most cost-effective and least-risk approach to retain the Galileo scientific objectives is to delay the launch until 1984, and launch the orbiter and the probe separately", Dr Mutch said.

The delay, and the need for a double launch, will mean a considerable increase in the cost of the project. Originally, with a 1982 launch, this was estimated at about $450 million; the new estimate, including in particular the extra hardware which the double launch will require, is $675 million.

Dr Mutch told *Nature* that the new plans, which will involve launching the orbiter several weeks ahead of the probe, will not effect the scientific programmes, and could indeed increase the quality of the results. "Since there will be a separate carrier devoted to the probe, we can now optimise its trajectory to get the maximum coordination with the orbiter," Dr Mutch said.

However the delay could mean further problems for the Galileo programme from Congress, which will have to give its approval to the new schedule and the increased cost. Two years ago, a bid to kill the project by Representative Edward Boland, chairman of NASA's appropriations subcommittee, was defeated on the floor of the House, only after a massive letter-writing campaign by the academic community.

This year, given the delays with the launch, the House accepted an amendment to NASA's appropriations bill proposed by Mr Boland which would give the subcommittee power to veto any move to split the mission. This has been rejected by the Senate, however, and negotiations are now taking place to find an adequate wording to meet the House's concern for a review of the new plans, but without giving either legislative body veto powers.



Sticky problem for the space shuttle: some of these protective tiles came off in flight

NASA scientists are worried that Congress may try to reduce the costs by splitting the launch, and sending one half of the mission — possibly the orbiter — at a later date. They emphasise that NASA has no plans to split the mission in this way.

Meanwhile Dr Robert Frosch, administrator of NASA, told the House subcommittee that NASA calculated a 50-50 chance that the space shuttle would have its first flight by next summer. The flight was to have taken place this spring, but has been postponed after a series of technical problems. The most recent was replacing some of the thermal tiles, used to protect the re-usable shuttle when it re-enters the earth's orbit, which came unstuck during testing.

Admitting that this was a problem which "should have been clear sooner, but was not," Dr Frosch told the subcommittee that about 7% of the tiles so far tested had had to be replaced, implying a total of 2,400 out of the shuttle's 34,000 tiles.

Dr Frosch said that technical delays, in particular with the testing of engine performance, meant that the total cost of the shuttle development programme was now likely to be about 20% more than the initial estimate of $5.15 billion at 1971 prices. He told the subcommittee that NASA had made a number of management changes after investigations to discover why the shuttle programme had run into problems at this stage. But he emphasised that a major factor had been serious underfunding of the programme early on. □

IQ tests 'unconstitutional'

In what promises to be a landmark decision after a seven-year court battle, San Francisco's chief district court judge, Robert Peckham, has ruled that the use of standardised IQ tests to categorise children as mentally retarded discriminates against minorities and is thus unconstitutional.

The immediate effect will be to make permanent a state-wide injunction against these tests and to force state officials to re-evaluate black children previously identified as "educable mentally retarded".

The judge struck out at what he called the "grossly disproportionate enrolments of black children in the so-called 'educable mentally retarded' classes". Although black children make up only 9% of the state school population, some 23% of the children enrolled in these classes are black. Not only is this unconstitutional, Judge Peckham ruled, but it violates federal civil rights laws and statutes dealing with education for the handicapped as well. He ordered state officials to "monitor and eliminate" the disproportionate placements. The complex case was launched in 1971 by civil rights groups acting on behalf of six black children in San Francisco — known only as Larry *et al*. The children had been placed in special classes because they had scored lower than 75 on IQ tests. When they were tested later by a group of black psychologists, their scores ranged from 17 to 38 points higher. State officials argued that the testing protocols and procedures used by the black psychologists violated accepted practice.

However, the case apparently was decided more on the basis of the general limitations of IQ tests rather than on the specific problems of these particular children. In testimony that ran for more than 10,000 pages, Peckham heard a wide

0028-0836/79/430618-02$01.00

range of arguments over the validity and proper use of IQ tests. Interestingly, neither side took a firm stand on the issue of whether or not "intelligence" as so measured represents an in-born ability. Rather, attorneys for the children argued that the tests are culturally biased, while the state argued that the tests remain good predictors of school performance for blacks as well as white.

The judge said that, in his opinion, "many black children have been isolated, stigmatised and provided with inadequate education on the basis of unwarranted and impermissible assumptions". The tests, he said, had not been modified or validated for blacks, while "almost no experts now contend that IQ measures innate intelligence".

Beyond the issue of the tests, themselves, Peckham found that the special classes are designed to provide only a "limited, dead-end education for children who, while not severely retarded, are incapable of mastering the skills taught in a regular curriculum". Since placement is assumed to be permanent, he said, "the children assigned to those classes are unlikely ever to succeed in school, even if they are not truly retarded."

Black pupils: tests discriminate against them

Just what the ultimate effect of this ruling may be remains unclear. Despite the injunction, enrolment of blacks in mentally retarded classes remains disproportionately high. IQ tests can still be used to identify gifted children and those that qualify for some other special programmes. An appeal may be launched and related cases are pending in other parts of the country.

The case brought into full public view many of the problems related to IQ testing that have been argued about in scientific circles for many years. And there may be a growing sentiment in favour of paying more attention to "performance" rather than "ability". In an editorial following Peckham's decision, the *San Jose Mercury* suggested: "It would be far better for Larry P, and for students of every race, if educators would drop IQ tests entirely and rely instead on empirical evidence. Put the Larry P's in a regular classroom and see if they can handle the work. The time to move them into special programmes is after they have demonstrated an inability to keep up with their classmates."

John Douglas

Dispute over Dow Chemicals' theory of dioxin traces

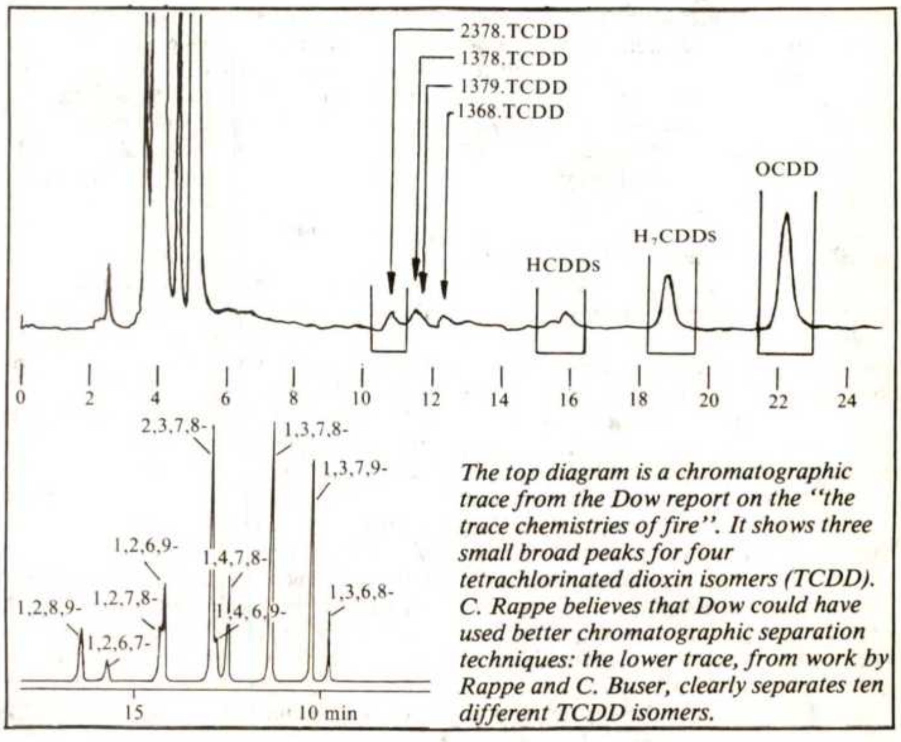
A Dow Chemical Company report on the toxic chlorinated dibenzodioxins, released in November 1978, has been severely criticised by Professor Christopher Rappe of the University of Umea, Sweden. He says that the methodology used by Dow is poor, rendering some of the results questionable; and furthermore, the conclusions — that dioxins are ubiquitous and a natural consequence of combustion processes — are far from proven. They are not borne out by results from Rappe's own laboratory.

The report, on "The trace chemistries of fire", was prepared for the State of Michigan's Department of Natural Resources (DNR), after Dow found that fish taken from the Tittabawassee River contained measurable amounts of chlorinated dioxins and polychlorinated biphenyls. Effluent from Dow's huge Michigan complex is discharged directly into the river and, not unnaturally, the company was assumed to be the source of the dioxins. Dow now dispute this charge: their report claims that dioxins are produced in many combustion processes, and are widespread. It has not convinced the DNR, however, which is insisting on additional measurements. Dr Robert Bumb, Director of Research at Dow's Michigan complex, believes that such additional tests would not only be expensive, but of little value; he says that other scientists are now confirming Dow's discovery.

Professor Rappe told *Nature*, however, that he disputes many of Dow's findings. Their discovery that dioxins are produced in commercial incinerators is not new, two independent European groups having reported earlier that the fly ash of municipal incinerators contains polychlorinated dibenzofurans. It was Dow's subsequent 'discovery' that chlorinated dioxins were present in the ash collected from other combustion processes which led them to develop their theory on the 'trace chemistries of fire'. Dow claim that dioxins are also present in ash collected from chemical tar-burners, fossil-fuelled power plants, the 'mufflers' of automobiles and trucks, household chimneys, cigarettes and even charcoal-broiled steaks. There had to be a common factor to explain the wide occurrence and Dow developed the theory of the trace chemistries of fire — defined as 'numerous chemical reactions occuring during combustion at very low concentrations, parts per million and lower'. Yields from these reactions are very low, of the order of 10^{-9} per cent.

The company attributes the formation of chlorinated dioxins to the presence of dioxin building blocks, which would include chlorine and chlorinated aliphatic and aromatic hydrocarbons. Metals present may act as catalysts "in a sea of chemical reactivity including pyrolysis, oxidation, reduction and acidloysis". In similar poetic vein, the report adds that in this sea, "ions, electrons, free radicals, free atoms and molecules form, combine and decompose". Chlorinated dioxins, Dow suggests, must be formed in this process.

Not necessarily, says Rappe. His results, those of colleague Dr Hans Rudolf Buser, and of Dr Hans Paul Bosshardt of



The top diagram is a chromatographic trace from the Dow report on the "the trace chemistries of fire". It shows three small broad peaks for four tetrachlorinated dioxin isomers (TCDD). C. Rappe believes that Dow could have used better chromatographic separation techniques: the lower trace, from work by Rappe and C. Buser, clearly separates ten different TCDD isomers.

0028-0836/79/430619-02$01.00

the Swiss Federal Research Station, all suggest that the dioxin precursors are not so nebulous. Rappe considers that chlorinated phenols and chlorinated diphenyl ethers are the main precursors in municipal incinerators. When these two groups of compounds are heated under laboratory conditions, Rappe has found that they produce isomers of chlorinated dioxins in similar proportions to those seen in commercial incinerators. Although Rappe forwarded his results to Dow, it appears either that they were not interested or that they chose to ignore his findings, for there are no analyses for these precursors in the Dow report.

The chromatographic separation techniques used by Dow to identify dioxin isomers are poor, according to Rappe, and their samples should be reanalysed using another method (see diagram on p619). In Rappe's opinion, Dow have overestimated the quantity of the dioxin isomer 2,3,7,8-tetrachlorodibenzo-p-dioxin (2,3,7,8-TCDD) which would be present in the fly ash of municipal incinerators. This isomer is many times more toxic than any of the other chlorinated dioxin isomers studied so far, and Rappe says that it represents only 1-3% of the tetrachlorinated dioxin isomers in European incinerator fly ash. Dow, on the other hand, report that in some cases 2,3,7,8-TCDD was the major tetrachlorinated isomer. Rappe suggests that this dramatic difference between his and Dow's results could be explained by the fact that Dow analysed samples from one of their own incinerators. Dow incinerates residue from the reactor used to make 2,4,5-trichlorophenol, the precursor of the herbicide 2,4,5-T. As the incineration of 2,4,5- trichlorophenol is known to produce 2,3,7,8-TCDD, Rappe suggests that the chlorinated phenol may have already been present in the reactor.

Rappe and his colleagues have so far prepared and identified 31 of the 75 chlorinated dioxin isomers which are considered to be theoretically possible. Although Dow used a far fewer (and unstated) number in its study, they believe that they identified enough isomers to make the report valid. In addition, Bumb points out that another Dow scientist, Dr D E Townsend has verified the trace chemistries theory from thermodynamic principles. Bumb told Nature that Townsend, in an unpublished report, finds a striking correlation between observed and predicted values for the dioxin isomers. Rappe disputes one of Townsend's assumptions (a constant ratio between dioxin isomers with different numbers of chlorine atoms): "consequently his basic theory is wrong".

Dow appears to be unaffected by the scepticism of scientists in Europe and the US. Bumb claims that "results which depart from traditional and commonly-held beliefs routinely provoke scepticism". And he remains confident in Dow's results and the company's conclusions.

Bumb and Rappe will have a further opportunity to put their respective cases in November, when both will present evidence in hearings organised by the US Environmental Protection Agency. The EPA is to consider its ban on the herbicide 2,4,5-T, which it has recently extended, from a restriction to forestry only, to a total ban covering all known uses of the herbicide in the US. The danger of 2,4,5-T lies in its contamination with small amounts of the dioxin 2,3,7,8-TCDD, one of the subjects of contention in the Dow report.

Alastair Hay

Israeli universities face financial crisis

ISRAEL'S seven institutions of higher learning have successfully resisted a recent attempt by the Knesset's Finance Committee to cut £8 million from their budgets.

A threat to double tuition fees or even close down campuses was enough to spur Prime Minister Menahem Begin to intervene. He successfully asked the committee to reverse its decision.

University officials are naturally relieved, but they are still fearful of future developments. Their mood was expressed by a top academic administrator who said that they "had won the battle and yet might go on to lose the war".

This is because the Knesset members who reluctantly agreed to restore the £8 million and many other influential Israelis apparently believe that the universities and academic research centres are characterised by luxury and waste, which means that they can more readily absorb budget cuts than can other institutions supported by public funds. And such cuts are inevitable if the rampaging, nearly three-digit inflation now plaguing Israel is to be brought under control.

The institutions of higher learning certainly helped to create their image in what Weizmann Institute President Michael Sela some years ago called "the Herodian era of construction", when universities, egged on by donors anxious to have their names associated with imposing edifices, seemed intent on surpassing one another in square metres of marble and concrete.

Yet there are also other, perhaps more significant factors at work. To some extent, as in the West generally, science and scientific institutions are held responsible in Israel for almost all the ills of modern society. In addition, parliamentarians concerned about the problems of the underprivileged and poorly educated sections of Israeli society are ready to divert scarce funds from universities and research centres to nursery schools, primary schools and secondary schools.

In any case, even before their latest tangle with the Knesset's Finance Committee, local institutions of higher learning were already suffering from a severe decline in government support. In the period between 1972 and 1978, when the national budget grew in real terms by 30%, funds allocated to higher education declined in real terms by 20%.

Making things even more difficult for the institutions is the erratic manner in which government allocations are dispensed. Money does not come in regularly week by week or month by month; instead most of it tends to arrive towards the end of the fiscal year.

Yet the universities are prohibited by law from withholding wages, and if they don't pay for their supplies, the supplies stop. This forces them to take high interest loans in order to bridge the gap between current expenditure and eventual government grants. University spokesmen claim that economy measures have already gone past the stage where fat was being trimmed and now are impairing their ability to operate properly. According to Tel Aviv University President Haim Ben-Shahar, "libraries and laboratories are no longer up to date. Journals containing important current research developments are sometimes impossible to acquire. Our scientists are forced to work with obsolete equipment, which, of course, puts them at a disadvantage in comparison to their colleagues abroad".

A research chemist at another institution told of a case in point. For some years, he said, the people in his department have been seeking funds to purchase a gas chromatograph mass spectrometer. At first they could go on with experiments by constantly tinkering with their old mass spectrometer, purchased in the early 1960s. But now some lines of research have had to be dropped as it is impossible to obtain relevant and significant results without the newer instrument.

Financial problems have severely limited the hiring of new staff, leaving institutions of higher learning with a disproportionate number of aging, tenured men and women. This news about job prospects has reached university students, and it undoubtedly has something to do with declining enrolments in the natural sciences.

Chemistry faculties are particularly hard hit, with registration down by anywhere from a quarter to three-quarters and some institutions now boasting more teaching staff than students. The same applies to a lesser extent to other science faculties. Students are now choosing short courses promising good employment prospects and the possibility of high financial gain.

Public spending cuts threaten UK universities

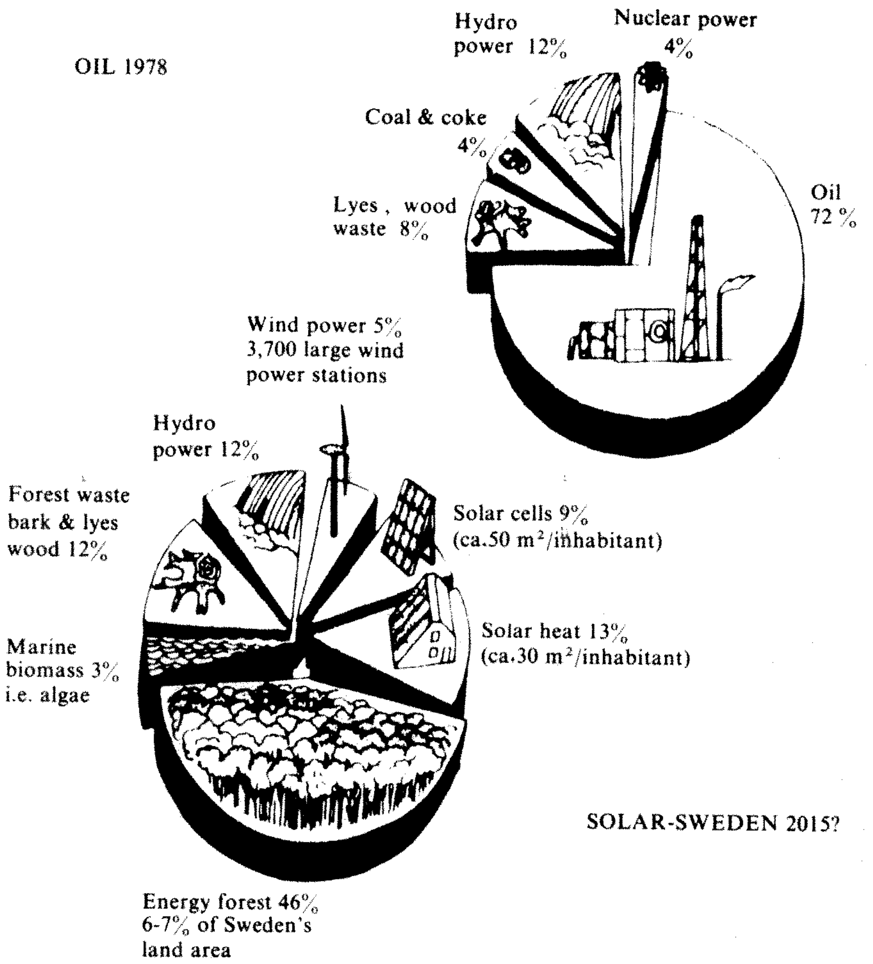
THE UK government is on the brink of a decision which could be disastrous for the country's universities, according to Sir Alec Merrison, Chairman of the Committee of Vice-Chancellors and Principals. Proposed cuts in funds would almost certainly mean the closure of some departments and even whole universities, he told a press conference last week, and universities would not be able to educate well-qualified home students whose numbers are likely to continue increasing over the next few years.

The CVCP was responding to the government's intention — outlined in a letter from the University Grants Committee to all universities last week — to hold the universities' recurrent grant at the 1979-80 level for several years and remove all UK government support for overseas students embarking on their studies on or after the 1980-81 academic year.

Cutting out funds for overseas students would result in a 13% fall in university income by 1983-84. The money could only be recovered if large numbers of overseas students were capable of paying their own fee — estimated at £3,500 each. This is highly unlikely, says the CVCP in a letter to Mark Carlisle, the Education Secretary. Overseas students would have to pay many times more to study in the UK than in other western countries and would therefore go elsewhere. British universities would cease to compete internationally. Some universities would be hit very badly, for example, the University of Manchester Institute of Science and Technology, a third of whose students come from overseas.

The vice-chancellors are concerned that research as well as teaching is bound to suffer. In looking for economies, universities would tend first to cut spending on research equipment. "The whole question of research is considerably at risk", Sir Alec said.

A further problem for universities is uncertainty about the 1979-80 level of funding which is to be used as the base for the recurrent grant until 1983-84. Salaries for university staff have yet to be agreed for the year ending July 1979 and the government has given no assurance that it will meet any increases. The CVCP is also concerned that pegging their future funds at 1979-80 levels will not take account of inflation and pay increases to come in the next few years. Many universities are already having difficulties existing on their funds. Sir Alec's own university, Bristol, ran up a deficit of £500,000 in an income of £25 million last year. "I'd be very surprised", he said "if there aren't some institutions that have had to go to the bank already." ☐



Changing the energy equation: how Sweden's forecasters see the future

Sweden warms to biomass power

INDEPENDENCE from oil as a source of energy was the basis of a Swedish contribution to a seminar on Technological Forecasting Methodologies recently held by the UN Economic Commission for Europe (ECE). The authors Thomas B Johansson of Lund University, and Peter Steen of the Swedish Research Institute for National Defence, suggest that 61% of the nation's energy could be provided by biomass. Six to seven percent of the country's land area, they propose, would be devoted to energy forests, estimated to yield 46% of the country's needs; forest waste and wood lyes (pulp effluent) would contribute 12% and marine biomass 3%. Other contributors would be solar heat (13%), conversion through solar cells (9%), wind, and hydro-power (12% — the same as the current figure).

No mention however is made of methane from the conversion of urban waste, a resource already used in some other north European countries. The figures are contrasted with those of the present system, which relies on oil for 72% of the country's needs, hydropower for 12%, woodwaste 8%, coal and coke and nuclear 4%. Neither coke nor nuclear appears in the 2015 forecast, which is said to allow for "moderately increased efficiency" and "twice the production of goods and services compared with today".

The authors have assumed that "the energy system should be fully implemented in the year 2015", and have calculated backwards the necessary rate of expansion. This gives 50% implementation from renewable resources by the year 2000. The rate they estimate is less than that estimated by the Swedish National Board for Energy Source Development. At the same time the cost of the proposed system is "not in conflict with production levels assumed for the whole economy" while it is based on a continued increase in labour productivity.

But there are difficulties. For example, there are to be major political and economic issues with regard to land-use policy and the capital market, since the proposals would require more land area and are more capital extensive than the present energy system. However, Sweden is already very advanced in research on energy plantations, making use of selected strains of various tree species grown on a short rotation system and giving yields comparable to those found in the tropics.

Two German papers at the seminar, however, estimated that solar energy would contribute only 5% of all energy by the year 2000. They paid little attention to the indirect uses of solar energy through biomass conversion or the better use of wood and wood-products. However, several other ECE meetings have been

0028-0836/79/430621-02$01.00

devoted to the energy aspects of the forest industries. At one it was indicated that the energy input of the industry itself to pulp and paper manufacture ranged from 5-35% in different countries, with a very much lower figure (5% only) for the input to the mechanical processing side. Sweden, again, is a leader in examining how these figures could be improved by more efficient use of forest waste: one recent estimate gives 50 million m^3 of residues consumable as fuel if not partially recovered for other processing, for every 60 million m^3 of commercial round wood produced annually.

Again, in Finland it is estimated that small sized wood, stump/root systems and other forest waste could provide 3.6 million tons oil equivalent a year, with another 0.8 mtoe depending on the market for certain hardwood products. Timber industries, faced with rapidly rising energy costs from conventional sources, are examining new ways of using their own waste products, either by direct combustion or through conversion into gas or liquid fuels. An advantage is that wood is not carcinogenic and is low in both nitrogen and sulphur. According to one ECE reort, forest product industries can and should become energy independent soon, later supplying surplus biomass to other users.

Peter Collins

Poland calls for wider research cooperation . . .

International cooperation at every level — from pure academic research to industrial design and implementation — is essential if a country's research potential is to develop to its full capacity. So Jan Mazurkiewicz, Director of 'Export and Economic Relations with Abroad' of the Polish Ministry of the Machine Industry told *Nature* recently. He was summarising the significance of "Poland's Technology, 1979" a series of seminars and technical exhibitions held last week in London, Manchester, Birmingham, and Coventry.

The close integration of research with industry is a basic feature of Polish planning. It was perhaps less familiar to some of the British participants, who seemed a little at a loss as to whether to expect learned discourses or sales promotion talks. For the event, sponsored on the British side by the Chambers of Commerce of the host cities, was the reciprocal or a similar British week in Warsaw last autumn, and represents one of the more positive results of Poland's large trade gap with Britain.

If trade between the two countries is to increase — and the state of the Polish economy makes this highly desirable — some new form of cooperation must be found. Recently, joint research and development projects, culminating in joint production for a third market, has increasingly been proposed on both sides as an attractive solution.

Any viable proposal for joint projects presupposes, that both sides know what the other has to offer. "A symposium means the meeting of people with like interests", Mr Mazurkiewicz explained. "So we chose our team very carefully — a couple of academicians, a test pilot, two plant engineers, an administrator, and so on. We looked for a good variety, for people with open minds, with whom there could be a point of contact."

The subjects, which ranged from medical electronics to machine tools and from computer software to agricultural aviation, were selected by the Polish side as fields where they felt they had something valuable to offer. Inevitably, in the discussion of any cooperation projects, sooner or later the problem of strategic military embargoes crept in. These, however, were peripheral, and in one instance, Jacek Szporko of "Unitra-Elektron" joked that the strategic embargo of the early 1960s had indirectly led to Poland's present expertise in semiconductor technology.

The close links between Polish research and industry meant that the Polish team could include lecturers of considerable international standing. Andrzej Radziminski (software and computer services) is a member of the Advisory Committee for Informatics Projects of the International Bureau for Informatics Dr Tadeusz Zak, who lectured on the Polish technological equipment industry, is a member of the Comecon Plenipotentiary Committee for Corrosion Problems, and Dr Halina Leszcynska (industrial sulphur processing) was closely involved in the development of granulated sulphur. This is free of the health and environmental hazards that had been closing more and more ports throughout the world to sulphur in its traditional powder form.

Dr Leszczynska is a member of the Committee of Chemical Sciences of the Polish Academy of Sciences, and, as such, represented a field which, she said, is always in the "top three places of research investment", due to its "importance in the national economy". She was particularly optimistic about the outcome of the week. "There are already a lot of people doing joint research at post-graduate level", she said. "What this week has done is to provide new direct contacts at the development level."

Several members of the Polish team, in informal discussions, suggested that joint industrial and development projects should ideally be based on truly joint research, rather than bringing together the results of research at a late stage.

Although the symposium, was slanted rather towards the industrial end of the research and development strectrum, the lectures from time to time revealed interesting sidelights on Polish research structure which would undoubtedly have to be taken into account in the planning of any joint research. Who would have guessed — until test pilot Wieslaw Mercik pointed it out — that the Warsaw Aviation Institute does no work at all on whole-body helicopter design, but is simply responsible for testing the aerodynamic and performance characteristics of designs produced in the factory design offices?

Vera Rich

. . . while the East Germans must wait for a trade agreement first

THE German Democratic Republic, which celebrated its 30th anniversary recently, is a country where, according to Dr Lutz Buschendorf, First Secretary (Science and Technology) of the GDR Embassy in London, every single worker is to some extent involved in science. Unfortunately, he said, so far scientific cooperation between the UK and the GDR has not developed to the extent one might have hoped. The reason, from the East German point of view, is the "unwillingness" of the UK to sign a cooperation agreement in which science and technology would not be linked to trade.

At present, technological cooperation comes under the Joint Agreement, originally drawn up in 1973, in which the British side comes under the aegis of the Department of Trade. This is the standard situation for all UK cooperation deals with Eastern Europe. The involvement with trade has a two-fold basis. Firstly, from the beginning, the UK felt that if the agreements were to bring genuinely mutual benefits, then some kind of counter-trade would be needed to off-set a predominantly one way, West to East flow of technology. Secondly, the administration of the agreements by the Department of Trade (via a special technology unit) is a result of the way the ministry of technology was dismantled.

To the East Germans, however, the link with trade constitutes a major psychological block. When the then UK Secretary of State for Trade, Edmund Dell, visited the GDR some three years ago, he stressed that under existing economic conditions the trade turn-over between the UK and the GDR could well be doubled. Some Germans seem to have taken this as a direct challenge to their thesis that increased scientific and technological cooperation should pre-date any major expansion of trade. "We want to make

0028-0836/79/430622-02$01.00

cooperation more long-term", Dr Buschendorf explained. "Under the present agreement it is difficult to get the right partners for scientific cooperation".

From the German point of view, the situation was somewhat improved by the signing, last May, of an agreement for the exchange of scientists, between the Royal Society and the GDR Academy of Sciences. Otherwise, however, they remain intransigent that what they need is a separate cooperation for science. They do not even seem willing to discuss possible areas of cooperation until such an agreement is signed — even to suggest subjects, Dr Buschendorf felt, would be "premature". It is known, however, that the British side has put forward a number of concrete proposals for joint seminars and visits, in order to bring together specialists who could then discuss feasible cooperation programmes. Subjects in which Germans have indicated particular interest include industrial hydraulics and corrosion protection. So far, however, there has been no firm response.

The insistence of the GDR on keeping science and trade firmly separated seems a little incongruous in the light of its own science policy. This, according to the official hand-outs for the current anniversary, is based on "a close and desired connection" between research and "the tasks set in the national economy". Innovation and implementation are the keynotes, and workers at all levels are encouraged to suggest further possible improvements. There are close funding links between industry and basic research. The production of university graduates is also a part of state planning, and each student is provided with his or her future job at least a year before graduation.

Given an economic structure, where "all the planning of scientific and technological work is based on the requirements put on the development of the national economy", it is difficult to understand the Germans' reluctance at least to explore what can be done under the existing agreement. Many of the fields which have priority in the GDR research programme — environment, water pollution, energy and raw materials, computers, could provide considerable scope for joint work with the UK or other western countries.

Perhaps some part of the explanation may lie in a report produced last spring by the East Berlin Institute for Politics and Economics. The Institute team, it appears, was apprehensive that injudicious importing of licenses could harm indigenous research and development by turning the national research potential into a mere mechanism for the adaptation of foreign thinking.

So far, however, no negotiators have made any reference to this point of view, but, on the thirtieth anniversary of GDR statehood, have raised yet again their plea for a separate scientific agreement.

Vera Rich

Soviet scientist proposes Siberian sites for nuclear power stations

Soviet nuclear power stations should be sited in remote regions of Siberia and the Far North, according to Academician Nikolai Dollezhal' a leading nuclear scientist, and Yurii Koryakin, a Doctor of Economic Sciences. Moreover, such power stations should take the form of large "nuclear energy complexes", each consisting of a number of power stations of "several tens of millions of kW capacity" together with fuel reprocessing plants, and possibly facilities for utilising nuclear byproducts.

This proposal, which the authors themselves admit is "radical", appeared in the September issue of *Kommunist*, the leading Party theoretical journal. Starting out apparently as an encomium of Soviet nuclear progress, the tone gradually becomes less optimistic, and, after outlining the setbacks and delays of the fast breeder programme, the authors openly tackle the environmental problems, hitherto dismissed by Soviet publicists as scare-mongering by capitalist oil interests. Reprocessing risks are particularly stresed, and bolstered by the assertion that basic reprocessing costs are "significantly" higher than originally estimated.

Still more costly, they imply, is the loss in the productive land and water resources. Some 60% of the Soviet population live west of the Volga river/Volga-Baltic canal line. It is here, in the main area of industrial and agricultural production that it is currently proposed to site nuclear power stations. The annual water requirements of nuclear and thermal power-stations already exceed 100 km^3, some 2 km^3 of which are "irreversibly" lost. To accommodate this water, by the end of the century, if current construction patterns continue, agricultural land sufficient to provide bread for "several million people" will have been sacrificed.

Dollezhal' and Koryakin would not, they stress, cast any doubt on the "historical necessity" of nuclear energy. Without nuclear energy, they affirm "it is impossible to construct the energy basis of developed socialism".

Giant energy complexes in Siberia, they claim, might well prove to be more efficient as regards construction, operation, and the "utilisation of labour reserves". Environmental hazards would be removed to a safe distance, and those associated with the transport of fuel from reactor to reprocessing plant eliminated completely. Finally — and this might well be the point that would win over the decision makers — the proposed nuclear complexes could be integrated into the Soviet Union's most prestigious civil engineering project — the diversion of the Siberian rivers to replenish the arid south.

Vera Rich

Physicist flown home to face charges

Franco Piperno, the Italian physicist who had asked for political asylum in France, was extradited to Italy last week. The extradition order was given a week in advance of its scheduled hearing to avoid demonstrations and rescue attempts.

Piperno, aged 36, was escorted from Sante prison at 7am to Le Bourget Airport where an Italian Air force plane took him to the small military airfield, Practica di Mare, north of Rome. He was whisked to solitary confinement in the political wing of the modern Revibbia jail in Rome.

Students in Rome set fire to cars and buses to protest at Pierno's extradition from France and police fired volleys of tear gas in unsuccessful attempts to disperse the demonstrators.

Forty five counts of extradition ranging from stealing car license plates to armed insurrection and including offences against the highway code were rejected by the French Court of Appeal (as was a first extradition request) on the grounds that they were political in character and violated the 1870 extradition treaty between the two countries.

But the court released Piperno to the Italian authorities to answer charges that he had sheltered two men in whose homes Italian police had found guns allegedly used in the abduction of Aldo Moro. Moro, one of Italy's political elder statesmen, was kidnapped and later killed by the Red Brigade guerrilla group in Rome after their attempts to exchange him for jailed comrades had failed.

Piperno had denied involvement in the Moro affair. His statement at the extradition hearing was: "Perhaps it is better this way. At least I will be able to confront quickly that which in Italy is called justice and to demonstrate that I was not involved in the Moro kidnapping and assasination."

In Paris, where Piperno had received widespread support, French commenators expressed dismay and anger at the extradition. Francois Mitterand, leader of the Socialist opposition, declared that the Socialist Party "deplores the fact that French judges have yielded to governmental pressures". And Phillipe Boucher, writing in *Le Monde*, said: "It is plainly unreasonable to believe that Italy had no political interest in brandishing Piperno as proof of their determination to combat terrorism. No one can seriously maintain the contrary . . . The (judicial) method in this case is contestable, indeed unseemly. It is furthermore dangerous." ☐

Who shall inherit the seeds of the earth?

"Seeds of the Earth", the study recently released by the London-based International Coalition for Development Action (ICDA), raised several issues of international concern. The study's author P R Mooney predicts that the Green Revolution is now moving into its second phase — a dangerous phase in which the responsibility of plant breeding is largely being left to the large private multinational companies. The study contends that new legislation in the developed countries which gives patent-equivalent protection to producers of new varieties of plants is helping the multinational corporations to acquire dominance over the seed market.

These trends are dangerous, according to the ICDA study, because of the gradual erosion of the world's plant genetic resources that is taking place all across the Third World. This erosion process has been accelerated in the last decade by the Green Revolution which has helped to bring vast areas under cultivation of monocultures. Deforestation is another aggravating factor. The Vavilov centres of genetic diversity (see map) — the geographical regions from which plant breeders draw a large part of their germplasm — are mainly located in the Third World. This germplasm is vital to the future food supply systems of mankind, as it is needed by plant breeders for further improvement of crop yields and incorporation of other desirable characteristics such as disease and pest resistance.

'Seeds of the Earth' points out that private corporate interests which are entering the seeds business are building up private gene banks to which access is limited only to the companys' plant breeders. This situation is particularly ironical for Third World plant breeders as Third World countries are the original suppliers of these plant resources.

Little is known about private germplasm collections, but the study does claim that "in some crops a single enterprise dominates total world germplasm holdings". "The FAC reports", says the study, "that one company, United Brands (formerly United Fruit), has about two-thirds of the world's banana germplasm in storage". Some public gene banks have had difficulty in obtaining information from private companies about the quantity of type of genetic material they hold.

At the international level, germplasm conservation is the responsibility of the International Board for Plant Genetic Resources which is based in Rome within the Food and Agriculture Organisation of the United Nations. The board co-ordinates the regional germplasm collection work that is being undertaken by the eight existing international crop research stations. There are also some 60 nationally-controlled gene banks. The germplasm collection work is massive and the board's activities remain clearly underfunded. There is little germplasm collection work being undertaken by Third World governments themselves, whose plant heritage is immediately threatened.

The ICDA study, therefore, recommends the creation of an annual emergency budget of US $100 million for the collection and storage of genetic material and creation of biosphere reserves. But equally important, the study points out, is the step that the UN should take to declare plants as "resources of common heritage to all peoples". There should be no form of legislation that allows exclusive control over plants. Secondly, the study recommends that the genetic material collected should be stored in the developing country from where it is collected. Most of the germplasm being collected at the moment is stored in the developed countries. If this trend continues, the Third World, the original supplier of this vital resource, could soon find itself dependent on the developed countries for the basic material required for its own plant breeding programmes.

The immediate target of attack of the ICDA study is the new legislation that is pending in several developed countries. This legislation provides patent-like protection to new plant varieties. It is the opportunities provided by this type of legislation — often called legislation for "plant breeders' rights" — that has encouraged the entry of big corporate interests, much to the detriment of the small breeders who are now being squeezed out of the market or being bought up. The ICDA study, in fact, claims to have been born out of the movement that farmers in Saskatchewan province of Canada have launched against the pending Canadian bill on plant breeders' rights.

Unfortunately, the study fails to provide adequate evidence for some of the charges it makes. For instance, the argument that the entry of agrochemical companies into the seeds business is "a way of assuring that one product line needs the other" remains at the moment a mere hypothesis. Patent protection for many important pesticides that were developed in the 1960s and earlier has already expired or is about to expire. This has raised problems for many companies which are now taking various steps to protect their interests either by diversifying into related areas or by somehow ensuring that their sales are not affected by expiry of patents. As agrochemical companies already have considerable scientific and technical expertise in various branches of agricultural sciences and a good marketing network that reaches right out to the farmers' fields, the seeds business may just be the ideal area in which to diversify.

Similarly, the World Intellectual Property Organisation which is responsible for the International Union for the Protection of New Varieties of Plants (UPOV) believes that the fears raised about the effects of the PBR legislation are exaggerated. An article of the International Convention for the Protection of New Varieties of Plants clearly states that no authorisation is needed to use a protected variety to produce yet another variety — except in the case where "the repeated use of the new variety is necessary for the commercial production of another variety," as in the case of hybrid varieties. Thus, the PBR legislation should not in itself prove to be a major impediment for further plant breeding work.

But despite its deficiencies, there is no doubt that the ICDA study raises several issues of major concern to mankind, and these issues needed to be fully debated to protect public interest, both in the developed and the developing countries.

news in brief

Birmingham University smallpox case starts: Legal action against Birmingham University under Section 2 of the UK 1974 Health and Safety at Work Act began this week in Birmingham. The university is being prosecuted by the Health and Safety Executive for failing in its obligation to "ensure as far as reasonably practical" safe working conditions in the east wing of the University Hospital. The release of smallpox pathogens from a P3 containment facility late in 1978 resulted in the death of a laboratory worker and closure of the facility. Under the terms of the act, the university could face a maximum fine of £1,000.

UK experts in occupational health regard the case as an important precedent that goes beyond the guilt or innocence of the university. It is the first prosecution brought against a university since the act was passed in 1974. Sheila McKechnie, health and safety officer of the Association of Scientific, Technical, and Managerial Staffs, said the case had given impetus to the campaign for laboratory safety. "The universities have been hiding behind a lot of 'frontiers of science' rubbish. They have been arrogant and have refused to acknowledge their obligations under the 1974 Act. The smallpox case has raised everyone's awareness of the extent of health hazards involved in university research", she said.

US studies identify formaldehyde as carcinogenic: Laboratory rats exposed to formaldehyde vapour have been shown to develop nasal cancer, according to tests submitted to the Consumer Product Safety Commission by the Formaldehyde Institute recently. A spokesman for the institute said that in the course of a two-year study, four rats out of a total of 720 tested developed tumours visible to the naked eye after 16 months, three after exposure to formaldhyde exposure at levels of 15 parts per million, and one at a dose level of six parts per million. Under existing standards promulgated by the Occupational Safety and Health Administration, worker exposure must be kept below three parts per million over an eight-hour period, or an average of five parts per million over 15 minutes. Mr John Clary, chairman of the institute's medical committee and a toxicologist with Celanese Corporation, said that the results were "significant".

ARMS to lobby parliament: ARMS, the Association for Researchers in Medical Science, are holding a day of parliamentary activity on 6 November. Members and supporters will assemble outside the Department of Education and Science to present a petition to the Secretary of State for Education and Science demanding "immediate action to implement a proper career structure for research scientists in biomedical research in UK universities and medical schools". A meeting is then planned with a number of MPs to discuss the position of medical researchers in the UK. An ARMS spokesman called the action "perhaps the last chance for researchers on short term contracts to discuss with MPs what is wrong with the current system of funding in the UK".

Chinese Minister of Education in whirlwind tour of UK: Mr Jiang Nanxiang, Minister of Education of the People's Republic of China, visited the UK from 28 September to 7 October to discuss scientific exchanges and to see British educational institutions. Mr Jiang, who had been relieved of his duties as principal of Peking University during the Cultural Revolution, was appointed Minister of Education earlier this year. He is said to be a believer in "quality education". The one-week tour consisted of visits to 18 UK educational and scientific institutions including middle schools, polytechnics and the Clarendon and Cavendish laboratories at Oxford and Cambridge. The Chinese delegation expressed particular interest in the Open University and its sophisticated system of correspondence courses, television programmes and regional tutorial centres. According to an OU spokes-person, the minister expressed interest in the regional centres, home experiment kits, and asked whether OU degrees were useful for "advancement and promotion". The university is designed to make university education more readily available to people from working class backgrounds but the Chinese minister expressed "little interest" in this aspect of the university's work, an OU official said.

India achieves breakthrough in fish culture: India's fish production may be revolutionised by a new composite fish culture technique developed by the Central Inland Fisheries Institute, (CIFRI), Barrackpore, West Bengal. The new culture technique uses a compatible fish combination of indigenous major carps and fast growing carps, and scientists testing this found yields as high as 6,500 kg fish per hectare per annum could be produced in some regions, although the project target had been only 3,000 kg fish per hectare per annum. This culture can be integrated with pig and duck culture, reducing the operational costs and producing 4,500 kg fish per hectare per annum and 1,800 duck eggs. Pig and duck excreta supply nutrients to the water, maintaining a high level of production. CIFRI's director, Dr V G Jhingran, estimates that if all India's present culturable waters are put to composite fish culture, average fish production will rise from 600 to 3,000 kg fish per hectare per annum. — *Zaka Imam, New Delhi*

Most blindness can be prevented: A meeting of an international group of experts on blindness has produced a report claiming that the incidence of blindness in the world can be halved quickly by simple and effective preventive measures. According to the report, most of the estimated 30-40 million cases of blindness are due to infection, malnutrition and cataracts. Visual impairment is 10–40 times more prevalent in certain areas of developing countries than in industrialised countries. The main obstacles to initiating a prevention campaign are a lack of national commitment, inadequate administrative infrastructure and a lack of money. The report also urges an avoidance of "the misunderstanding that equates the prevention of blindness with the availability of opthalmologists". The meeting was sponsored by the F.I. Proctor Foundation in San Francisco, The International Eye Foundation, and the World Health Organisation. *Guidelines for Programmes for the Prevention of Blindness.* World Health Organisation, Geneva, 1979. 47pp. Sw Fr 10.

IAEA reports 50% increase in new nuclear plants: The International Atomic Energy Agency in Vienna, in its annual survey of nuclear energy, reports that 15,000MW of new nuclear plants were installed in 1978 compared to 10,000MW installed in 1977. Nuclear power now accounts for 110,000MW or 5.8% of the world's total electrical generating capacity with 227 nuclear power stations operating in 21 of the agency's member states. The agency defends the safety record of nuclear power, citing "twenty years of commercial nuclear power generation without a single radiation-induced death or a serious radiation induced injury at any nuclear power plant".

EEC to spend £70 million on energy research: The Council of the European Communities is to spend about £70 million on a second four-year programme into energy research and development. The money will be allocated on the basis of shared-cost contracts over the four-year period 1979–83. Research organisations, industrial companies and universities will be eligible to apply and the first formal call for applications has been made by the EEC. Applications will be screened by an advisory committee which will make recommendations to the commission. The breakdown of the allocation is: solar energy, £30.7m; energy conservation, £18m; geothermal energy, £12m; hydrogen energy production,£5.3m; and energy strategy studies, £4m.

'There is a frustrating logical gap between the assertion that recombinant DNA poses potential risks . . . and the containment levels imposed by current guidelines'

Francis Rolleston proposes a formula to bridge the safety gap in recombinant DNA research and concludes that any approach which falls short calculation of the risks is necessarily misleading.

THE UK Genetic Manipulation Advisory Group (GMAG) has proposed an important new way to assess the relative possible risks of recombinant DNA experiments (9 November 1978, page 104), but it addresses only the assessment of risk, without establishing the necessary correlation between risk and the containment required to reduce the risk to acceptable levels. Here I will suggest a framework for discussion based on this essential correlation. This framework also offers a clarification of the roles of the scientists and the public in setting safety standards, and establishes a foundation for communication between them.

All current guidelines make quantitative statements; they are safety standards which state, in effect, that the inherent risks can be reduced to acceptable levels of public risk by the imposition of defined safety procedures. Yet these quantitative statements cannot be defended either quantitatively or logically. The guidelines therefore do not provide a foundation for rational interchange either among scientists themselves, or—more important—between scientists assessing risks and containment procedures and the public, who should be reviewing the assessments by the scientists and setting acceptable standards of public risk. There is a frustrating logical gap between the assertion that recombinant DNA poses potential risks on the one hand, and the containment levels that have been imposed by current guidelines on the other.

Logical guidelines must be both internally and externally consistent. Questions of internal consistency are illustrated by the option sometimes offered of a trade-off between physical and biological containment (do P2-EK1 and P1-EK2 offer similar containment?), or by the assignment of different experiments to different containment levels (are the same safety standards being achieved?). External consistency raises the question of whether the safety standards imposed for recombinant DNA are consistent with those required or accepted in other areas.

A conceptually simple framework that may meet these needs for consistency is offered by the formula for a straight line, $R = aC + T$. Here, R describes the risks inherent in cloning a certain gene in a certain host-vector system, C is the physical containment required, and t is a threshold level of acceptable public risk to which inherent risks (R) must be reduced, if necessary, by physical containment (C). In this general framework, the need for internal consistency is met if a, the slope, is equal to one. The value of T determines the external consistency of the containment requirements. The required distinction between the scientific and the public roles is achieved by recognising that the values of R and C are determined primarily in the scientific domain, whereas T should be set in the public domain. Both the numerical values and the explicit separation of the scientific and public roles in this equation allow—even force—the necessary interchange between scientists and the public.

In using this framework, the two variables R and C can be assessed in either an absolute or a relative sense. The absolute approach requires interrelated units in which to express R and C and therefore T. In the alternative approach, R and C do not have units, but are expressed relative to reference points; declaration of a relationship between the two reference points will define T, since the slope a must, for internal consistency, equal 1. The absolute approach is more satisfying, but probably can only be used in areas such as radiation damage or automobile travel where risks can be clearly identified and assessed; the relative appraoch appears preferable where risks are conjectural.

Such a relative approach to values for R was developed by Brenner and applied by Rigby, and their manuscripts formed the basis of the paper by GMAG. Their reference point was a very hazardous possible experiment in which the pure gene for cholera toxin is cloned and expressed in wild *E. coli*. The risks of other experiments relative to this reference were expressed in terms of three separate factors (damage, expression and access) which, multiplied together, gave values ranging from less than 10^{-16} to 1; these values were stated by the authors to be overestimates of relative risk.

The relative approach can also be applied to values of C. The reference point might be open to bench experimentation (P1 containment). With respect to researchers inside the laboratory, it can be suggested that a P2 laboratory offers perhaps 10^2 greater protection, allowing for the fact that the relative safety of a containment cabinet is limited by HEPA filter standards, and that not all procedures are carried out in such cabinets. A P3 laboratory offers perhaps a further protection of 10^2 since here airflow requirements reduce persistence of aerosols and more procedures are carried out in containment cabinets; and a P4 facility represents 10^6 greater protection than P1, again considering investigators inside the laboratory. Estimates for people outside the facility, or for the environment, result in smaller relative protection figures, since the only barrier is the HEPA filter, although the absolute hazards for those who work outside the facility are evidently much less than for those inside.

These primary figures illustrate how values for R and C might be developed by the scientific community. If the figures given have any significance the range of values for R is much greater than that for C. Therefore, the value assigned to T by the public process will determine whether some possible experiments are too hazardous to be performed at even the highest levels of physical containment, or alternatively other experiments present such low hazards that physical containment measures are superfluous; or perhaps both. If, for example, the reference experiment of cloning the

---

The author is director of special programmes for the Medical Research Council of Canada, with responsibility for regulating recombinant DNA research.

0028-0836/79/430626-02$01.00

cholera toxin gene in a wild type *E. coli* requires P4 containment—stated by the Council of the Royal Society Report (*Nature*, 15 February, page 509) to be too severe a level for *Vibrio cholerae* — then any experiment with values for R less than 10^{-6} (the resulting value of T) can be performed at P1 or less containment. From the above figures, it appears that this would include most experiments now requiring higher levels of containment, and it would, in large measure, incorporate the conclusions reached at Falmouth, Ascot and Wye.

A second conclusion from these tentative ranges of R and C is that the value of a is considerably greater than one in the original American, British and Canadian guidelines (which tended to spread the range of experiments across the available physical containment levels) and even in the revised American and Canadian guidelines. Therefore, if it is claimed that the more hazardous experiments have been appropriately contained, then those with less risk have been over-contained; conversely, if the apparently less risky experiments have been set at suitable containment levels, then containment standards for those of greater hazard have not been strict enough. Extrapolation from current scientific opinion (as expressed at Wye, without as yet any voice to the contrary) indicates that, if one must choose between these two claims, the former would be more accurate.

This proposed framework rests on assigning numerical values to risks and containment. Such an approach has been criticised (15 February, page 509 and 8 March, page 113) as being too imprecise because the risks are conjectural and probabilities of human error cannot yet be assessed. However, the current approach to guidelines makes just such judgements without admitting to them. A formal framework for setting safety standards which also segregates the scientific and public roles, while providing a means of communication, may focus attention on specifics as opposed to generalities, and require those who make pronouncements of doom or optimism to define their statements more accurately. □

I thank Mark Pearson for a most useful discussion of the manuscript, and John Keyston whose comments in September 1977 on the need for interrelationships between risk and physical and biological containment I did not understand at the time.

MIT puts some polish on a tarnished image

The Massachusetts Institute of Technology has raised $4 million to establish an ambitious College of Science, Technology and Society. Supporters say it will help give MIT-trained scientists and engineers "an education for the 21st century"; others claim it is an attempt to protect private industry from criticism of its use of science. **David Dickson** reports

WHEN Dr Paul Gray spoke to the press earlier this month following his election as the next president of the Massachusetts Institute of Technology, he placed particular emphasis on the steps which the institute is taking in response to public criticism of the social impacts of science and technology.

The current centrepiece of this face-lift is an ambitious plan to create a new College for Science, Technology and Society at MIT. Already $4 million has been raised from outside to support the project; and a programme of research and undergraduate teaching has begun as a development phase, supported by a number of eminent faculty appointments (including the historian of science Thomas Kuhn).

There is nothing particularly unusual about a technological university starting a programme in this area. What distinguishes MIT's efforts, however, is partly the size and scope of its commitment; and partly the fact that the programme is less a direct product of concern about the social impact of science, than a second order "reaction to public reaction" about such impact, such as the growing debates over issues from nuclear safety to the carcinogenicity of food additives.

And this has provoked its own controversy. The architects of the course claim that it is "a way of matching the maturing desire of MIT to go in this direction with the maturing needs of the nation"; critics warn that the institute is being used to promote the strategies of private industry in politically charged debates over technological risks and the appropriate social response.

Despite outward appearances, MIT is no stranger to the humanities. Various moves have in the past been made to complement its more scientific and technical courses; the Lewis Report of 1949, for example, led to the setting up in the 1950s of both a school of humanities and social sciences, and the Sloan School of Management. More recently, there have been particular developments such as a Technology Studies Programme and a Technology and Culture Seminar.

The aim of the proposed college is to focus these various activities and give them a new prominence within the institute. The move stems largely from an initiative taken by Dr Jerome Wiesner, ex-science adviser to President Kennedy and current president of MIT, who set up a faculty task force in 1973 to advise on how these goals could best be achieved.

After consulting with numerous individuals inside and outside MIT, the task force recommended the setting up of an independent college, with its own faculty, research fellows and undergraduate teaching programme. Based on this report, the institute raised $2.5 million in 1977 from three foundations,the Sloan Foundation, the Mellon Foundation and the Flora Hewlett Foundation; a further $1 million was added this year from the Max Fleischmann Foundation for renovating an appropriate building, and a $500,000 grant for a fellowship programme was made by the Exxon Foundation.

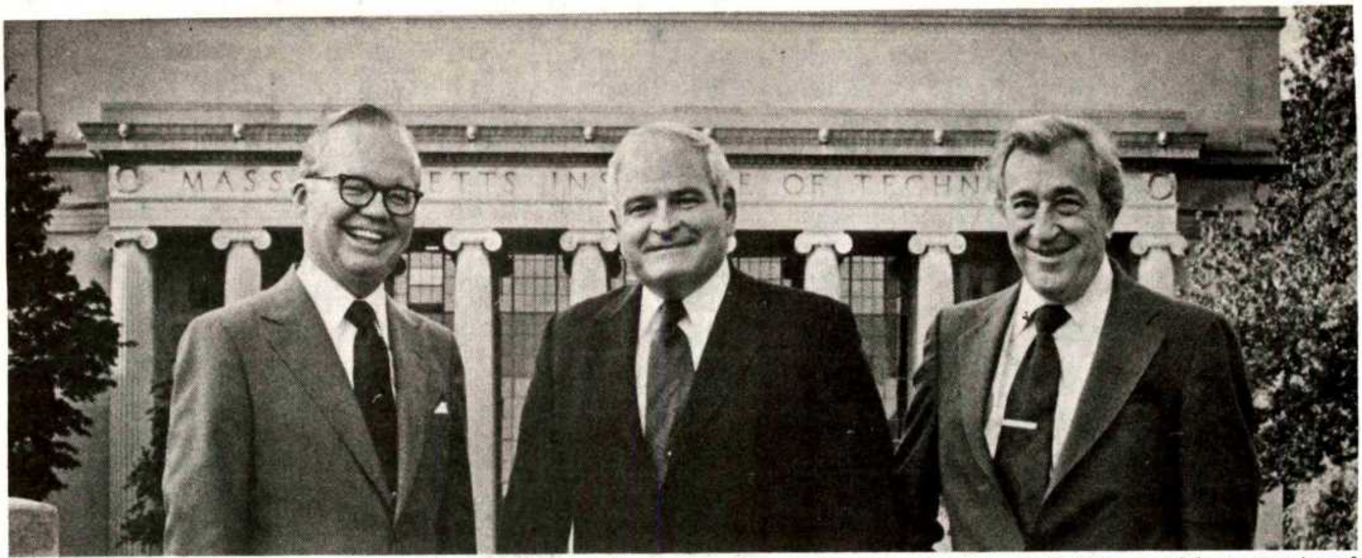
With this support under its belt, MIT has already been able to make seven new tenured appointments, and introduce a new undergraduate teaching programme — technically under the school of humanities — in areas ranging from the history of science and technology to "science, technology and the organisation of industrial society". A fellowship programme begins next year.

From the beginning, those responsible for the programme have emphasised that a high academic standard is necessary to avoid the 'credibility' problems associated with many previous attempts at multidiscipinary education. At the same time, however, it is stressed that the programme is also to be of direct use to the future scientist or engineer.

The 1977 prospectus for the college, for example, emphasises that the students will acquire "marketable knowledge", and that they will be "more effective professionals for this knowledge".

"The trends in terms of public perception of the implications of science and technology for society are continuing to mount, even if students are less vocal about it than they were at the beginning of the decade," says Dr Donald Blackmer, director of the new programme and deputy dean of the school of humanities. "The converse of this is that scientists and engineers are increasingly concerned about the impact of government and public attitudes on what they do."

This impact is felt both on the application of science, and on its practice. Dr Wiesner, for example, has been an outspoken critic of the extent to which social controls manifest as government regulation may be holding back both industrial innovation and university research. Addressing a meeting of the National Council of University Research Administrators in Washington earlier this year, he stated that "In the technical realm we can see many ways to continue humanity's forward march, if we do not



Behind MIT's new image: President Jerome Weisner (right) and his successor-to-be, Dr Paul Gray (centre). Left: chairman of the corporation of MIT, Howard W. Johnson

put too many shackles on those elements of society — universities, business, even some parts of government — that have made our technological achievements possible."

Closer to home, MIT biologists have had direct experience of the fierce and acrimonious debates that have surrounded the use of recombinant DNA techniques. Many were involved in public discussions over the extent to which the City of Cambridge should be permitted to exercise controls over such research.

Some now argue that it was a mistake ever to have raised publicly the potential hazards of this work. But Professor Gerald Holton of Harvard University, a visiting professor for the STS programme, argues that despite the "great cost and anguish", the debate was a "historic necessity", and that the main dangers lie not in attempts to restrict research as such, but the fact that they may be imposed from outside through an "uninformed bureaucracy".

"Scientists should not be pushed into a defensive position, when it has been the scientists who have historically dealt with self-imposed limitations, such as the discipline of the peer-review process. They should be aware that including these new issues is part of an on-going maturing of the profession" Professor Holton says.

Thus a general concern, not so much the need to control the uses of science as the institutional forms through which society has chosen and is likely to choose to exercise this control, forms a backdrop to the activities of MIT's new programme. In terms of study groups and lecture series, these range from topics such as technology and work, or risk and regulation, to environmental studies and the role of computers in society.

This concern is also directly linked to an issue which has caused considerable discussion within the programme faculty, namely the extent to which it should get explicitly involved in issues of public policy. Initially there was a certain reluctance to do so from anything more than a long-term, "basic research" perspective, a tendency illustrated by the high proportion of historians among initial faculty appointments.

More recently this emphasis has shifted, largely under promoting from Dr Wiesner, who stresses the "unique contribution" that universities can make to problems "that require mixed solutions that are at once technical, managerial, political and social." Dr Blackmer talks about bringing in more policy people as helping promote "a useful dialogue"; Professor Walter Rosenblith, MIT provost and, like Dr Wiesner, a fervent supporter of the college, speaks of the advantages of maintaining a "creative tension". But moves towards the policy direction — natural as they may be for an instititution with such close links to Washington policy-makers as MIT — have also exacerbated tensions with radical critics who, while intially keen that MIT should expand its efforts in the "science and society" area, now express concern about the way that this is being done. "It is certainly very important to study these issues, but establishing a research programme is no substitute for responsible social action on the part of scientists and technologists; the message of the college is that these controversies are matters for academic experts," says Dr Jonathan King, professor of biology and an active participant in recent DNA controversies.

Dr Blackmer expresses concern about the criticism that individuals who have been raising these issues on the campus have been excluded from the programme. But he defends this as the result of the need for a high level of academic credibility.

Here, too, however, there is a source of controversy. Dr Wiesner and Dr Rosenblith — both of whom have been asked to join the programme after their respective retirements next year — have publicly argued that universities can bring rationality to public debates about the risks of technological developments.

"University research, with its capacity to be comprehensive and with a credibility based on objectivity, can play an especially important role in studies aimed at clarifying for government the elements of conflicting social goals," says Dr Wiesner.

Critics, however, pointing to factors such as the sustained high profitability of chemical companies claiming to be overburdened by regulation, argue that the current 'debates' about risk are being partly managed as a public relations exercise by industry as part of a more general attack on social controls — and that MIT's academic credentials are being used to legitimate such tactics.

"There is a growing danger that, by recruiting university scientists to study these problems, private corporations are consciously trying to immunise themselves from public scrutiny by invoking both the scientists' stance of neutrality and objectivity, as well as the more general academic respectability of interdisciplinary programmes such as STS", says Dr David Noble, an associate professor of history.

Dr Stephan Chorover, professor of brain sciences and a long-term campus activist, puts it even more strongly: 'The bottom line is that the college is an exercise in what I call the engineering of consent: the product of a marriage between corporations with a large amount of money and low public credibility, and an institution that lacks the money but can provide the credibility."

Such criticism is not confined to plans for the college; another target is a new proposal, eagerly supported by some faculty members but criticised by others, that MIT should set up a "risk institute" largely at the behest of industry specifically concerned with technological risks and regulatory responses.

Given MIT's pre-eminence in what STS faculty member Dr Leo Marx has described as "the institutional embodiment of perhaps the major theme in the development of Western culture since, roughly, the seventeenth century", the outcome of the various debates will be watched with particular interest. ☐

Pathways to secretion

by Peter Newmark

OF the complex series of events that culminate in the secretion of products from cells, most can still only be classified as phenomenology in the view of G. Palade (Yale University), expressed at a recent meeting.* Although several attractive candidates are currently vying for recognition as molecular mechanisms of secretion, so far that accolade has only been conferred on the signal hypothesis.

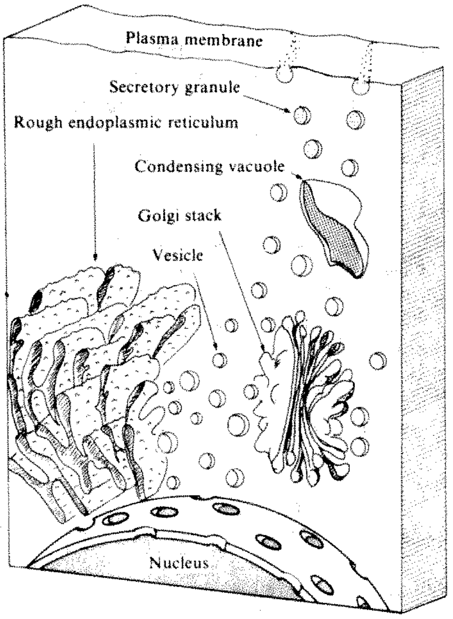
The signal hypothesis implies that proteins destined for secretion are synthesised with a sequence that guides them (and the ribosomes on which they are being synthesised) to the membrane of the endoplasmic reticulum (ER). As synthesis proceeds the nascent protein passes through the membrane into the lumen of the ER and from there, eventually, to and/or through the external membranes of the cell. Much evidence favours this concept, especially in the form in which the signal is a short, predominantly hydrophobic, amino-terminal sequence which is cleaved off as the protein traverses the ER. V. Lingappa (Rockefeller University) made the point that the concept could survive examples of non-terminal signals thereby rationalising the evidence he presented for the existence of an internal and non-cleaved signal sequence in ovalbumin (see *Nature* **281**, 117; 1979).

One prediction of the signal hypothesis is that the addition of a signal sequence to a non-secreted protein will lead it to be secreted. Another is that without the proper signal sequence a secretory protein will not be secreted. J. Beckwith (Harvard Medical School) described experiments with *Escherichia coli* mutants that have borne out both predictions. To test the first, genetic recombination was used to replace the amino-terminus of β-galactosidase (a cytoplasmic protein) with the amino-terminal sequences of either the maltose-binding protein (found in the periplasmic space between the inner and outer membranes of Gram negative bacteria) or the phage lambda receptor (an outer membrane protein). Either grafted signal sequence had the predicted effect of redirecting β-galactosidase from the cytoplasm to within, if not through, the bacterial membranes.

The *E. coli* with mutant β-galactosidase stuck in their inner cell membrane became phenotypically abnormal when induced with maltose. This led to confirmation of the second prediction of the signal hypothesis. For it was possible to isolate pseudorevertant bacteria which did not assume an abnormal phenotype when induced with maltose. These pseudorevertants did not have membrane-bound β-galactosidase. Genetic mapping showed this to be due to a mutation in the signal sequence region. Genetic recombination enabled the mutated signal sequences to be fused back to their normal proteins, maltose-binding protein or the lambda receptor; whereupon they were no longer secreted. Finally the exact mutations of the signal sequences that prevented their functioning were determined at the DNA level and sometimes at the amino acid level too. In most cases the change was of a hydrophobic to a charged amino acid.

Once across the rough endoplasmic reticulum and into the cisternal space, proteins are *en route* to secretion. But not all of them become secreted. In particular, certain enzymes are destined instead for the lysosomes. W. Sly (Washington University School of Medicine, St Louis) suggested that lysosomal enzymes are diverted from secretion by means of another signal, a mannose-6-phosphate group on a complex oligosaccharide group that is added to the enzymes in the cisternal space. The mannose-6-phosphate then acts as a recognition marker for receptors on the cisternal side of the endoplasmic reticulum membranes, the ligand-receptor complexes being internalised into vesicles which become lysosomes. These events, Sly believes, take place before the proteins reach the Golgi complex. If the mannose-6-phosphate recognition marker is missing from lysosomal enzymes they are secreted instead; this being the molecular basis of I-cell disease.

Although an exposed mannose-6-phosphate group may be unique to lysosomal enzymes, the presence of an oligosaccharide group is a common feature of secreted proteins. The groups are synthesised on a lipid (dalachol) carrier, added to the proteins during or shortly after translation, and processed before or in the Golgi complex (M. Snider, Massachusetts Institute of Technology). Although the role of these oligosaccharides is not clear it is possibly in the routing of the proteins to their final destination. A genetic approach to this problem may be found through the availability of temperature-sensitive mutants of vesicular stomatitis virus, the spike glycoproteins of which do not reach the surface of infected cells at the non-permissive temperature. Some of the glycoproteins do not acquire normal terminal sugars on their oligosaccharide side chains, although at least one does (H. Lodish, Massachusetts Institute of Technology).



Secretory pathways in the cell (adapted from *Functional Histology* (Wheater, Burkitt & Daniels) page 12, Churchill Livingstone).

Molecular mechanisms which are tentatively related to secretion were outlined by H. Pollard (NIH) and T. Stossel (Massachusetts General Hospital). Pollard described a protein, synexin, which can aggregate isolated chromaffin granules

---

*Basic Mechanisms of Cellular Secretion, sponsored by the NIH and held in Annapolis, 17-21 September, 1979. A book based on the conference will be published by Academic Press in 1980.

Peter Newmark is Deputy Editor of Nature.

0028-0836/79/430629-02$01.00

in the presence of calcium. By analogy he believes that an influx of calcium into the cell would induce synexin-mediated fusion of chromaffin (or other) granules to the plasma membrane. For discharge of the contents of the granules another mechanism is needed. That, according to Pollard, involves the opening of an anion transport channel at the point of contact between the vesicle and plasma membrane leading to a chloride and energy-dependent chemiosmotic lysis of the granule. Stossel has a scheme whereby calcium activates the macrophage protein gelsolin (*Nature* **281**, 583; 1979) to reduce the length of the actin polymers of the cytoskeletal lattice. As a result he envisages that an influx of calcium could induce a local contraction of the lattice allowing access of the secretory granules to the plasma membrane.

Both of these speculative mechanisms involve triggering by an increase in the level of calcium ions, one of the best established features of stimulus-induced secretion. O.H. Petersen (Dundee University) described evidence from the pancreatic acinar cell that suggests the immediate release of calcium from an internal source in response to secretagogue stimulus. That calcium mediates the opening of ion channels for sodium and chloride, the influx of which accounts for the observed membrane depolarisation which is followed by secretion. Continued secretion requires the influx of calcium from an external source. That calcium may be brought into the cell by an ionophore. Candidate ionophores are phosphatidic acid (J. Putney, Wayne State University School of Medicine) and, at least in polymorphonuclear leukocytes, prostaglandin B_x (G. Weissmann, New York University School of Medicine).

The question of the route(s) of intracellular transport of secretory products from the rough endoplasmic reticulum to the plasma membrane remains vexed. The favoured scheme is one whereby vesicles are pinched off from the former and find their way to the distended ends of the Golgi stack. With these they fuse. What happens next is unclear but may involve passage of the secretory products to other sections of the Golgi complex, the GERL (several participants felt that this was no longer a useful concept) and the condensing vacuoles. Finally, from one or more of these morphological semi-entities, vesicles are again pinched off. These become the secretory granules as they head for the plasma membrane. What, if anything, guides or drives them there? One possibility for which the evidence is ambiguous, is that microtubules are involved. If so, it is conceivable that secretory granules are attached to the tubulin subunits of microtubules which, according to L. Wilson (University of California, Santa Barbara), are continually being added at one end, traversing the length and disassembling at the other end of microtubules of constant length. His latest evidence is that this 'treadmilling' is hastened by ATP, perhaps through the phosphorylation of one of the microtubule-associated proteins. The rate of treadmilling is thereby of the right order of magnitude were it to account for the conveyancing of granules to the surface of the cell.

Finally the secretory granule reaches the plasma membrane. Fission in the pancreatic B cell is preceded, according to L. Orci (University of Geneva) by the clearance of intramembranous particles and glycoproteins from the contiguous granule and plasma membranes. This is an observation common to many membrane systems but was disputed by T. Reese (NIH) for *Limulus* amibocytes observed with a time resolution of a few milliseconds. Orci also has very tentative evidence that the intramembranous particle-free membrane areas are rich in cholesterol, on the fiercely disputed assumption that it is aggregates of cholesterol which form the protuberances that are induced by addition of the antibiotic, filipin. These morphological correlates of exocytosis seem to be mirrored by an absence of filipin-induced protuberances and a concentration of intramembranous particles at sites of endocytosis on fibroblast membranes □

Jets in radio galaxies

from R.D. Davies

As higher angular resolutions become available to radio astronomers more evidence is coming to light on the important role of jets in the processes within radio galaxies and quasars. One of the first such objects to be discovered was the radio jet in the nearby radio galaxy Virgo A, also known as M87, the dominant galaxy of the Virgo cluster. This jet, seen at both optical and radio wavelengths, is a straight filament aligned precisely with the nucleus of M87; it lies to one side and extends 1.5 kiloparsecs (4,500 light years) from the nucleus. A similar geometrical arrangement occurs in the quasar 3C273, but on a larger scale; a straight jet projects 40 kiloparsecs from one side of the compact optical and radio quasar. The discovery of such jets lying relatively close to the nucleus of radio galaxies and quasars gave an impetus to the understanding of the huge outer radio emitting lobes. These are generally of similar intensity and lie a similar distance either side of a central object; the overall dimensions may be anywhere in the range of 100 to 3,000 kiloparsecs.

The arrangement of radio sources (it does not particularly matter whether they are radio galaxies or quasars) can be simply summarised. There are three main parts — a central power-house in which energy is released, an interconnecting region where energy is transmitted outwards and a large outer luminous region. Since these outer regions lose energy by radiation in a shorter time than it took them to expand out to their present position, the energy supply must be continually replenished. Therein lies the problem. The situation is analogous to the problem of supplying energy to a city from a distant coal-field. We might think of two ways of doing this. First, the energy could be converted directly into electricity then sent over transmission lines, or alternatively the coal could be transported by train and converted locally to the form of energy required. The same two alternatives have been proposed for radio sources. Rees has proposed that energy may be transmitted as intense low-frequency electromagnetic radiation which then penetrates to the outer lobes and causes them to radiate. Other theories have been conceived in terms of the mechanical transport of energy in which either cold gas or relativistic gas and magnetic fields are ejected at high speed from the nucleus and interact with the material in the outer lobes. The latter processes involving the mechanical transport of energy are more likely to produce observable radio jets.

New radio instruments with even higher angular resolution and sensitivity are coming into operation and are throwing light on the radio source problem. The pioneering instrument in this field is the Cambridge 5 km aperture-synthesis array; it has been for many years a major instrument in the study of structure of radio sources. It is now equipped with receivers at short wavelength to improve further its angular resolution. The Westerbork array in Holland is being increased in resolution by an extension of baseline to 3.2 km. The major development in this field in recent years is the Very Large Array (VLA) which is nearing completion in Socorro, New Mexico. The VLA will consist of 27 radio telescopes each 25 metres in diameter located on rail tracks in the form of a Y with each arm 18 km long. Higher resolution again will be achieved with the Multi-Telescope Radio-Linked Interferometer (MTRLI) at Jodrell Bank which will have telescopes distributed over baselines up to 133 km. The highest resolutions of all (milliarcseconds) are available with tape-recording interferometers on intercontinental baselines; these are particularly useful in probing the nuclear regions of radio sources.

The new observations of radio sources

R.D. Davies is Professor of Radio Astronomy at the Nuffield Radio Astronomy Laboratories, University of Manchester.

0028-0836/79/430630-02$01.00

with the partially completed VLA were a highlight of the recent General Assembly of the International Astronomical Union. 3C449 described by Perley, Willis and Scott (see *Nature* **281**, 437; 1979) is typical of the new data coming from the VLA. This is the radio source associated with a giant elliptical galaxy having a redshift of 5,400 km s^{-1}. The radio galaxy is typical of its class and has large outer radio lobes extending to 160 kiloparsecs on each side of the galaxy. What is particularly evident from the new results is the dominance of an inner jet structure lying symmetrically on either side of an unresolved nuclear source. These jets show a constant opening angle of about 7° which is most readily interpreted as arising from fast radial outward flow of emitting plasma in which there is also a transverse flow representing expansion at the speed of sound on the medium. A consistent picture emerges with a radial flow of about 1000 km s^{-1} which leads to a lifetime of 10^7 years for the bright inner jets.

In addition to the bright jets and the faint but extensive outer lobes there is an intermediate region of enhanced brightness. In all, there must have been three major outburst phases in 3C449, in each of which material was ejected outwards in opposite directions on more or less the same line. As the emitting plasma moves outwards it expands and becomes of lower surface brightness. Indeed the authors interpret the gap between the nucleus and the inner edge of the jet as indicating that there may have been an interval since the last outburst of a few million years. These observations clearly favour an explanation in terms of a mechanical flow of energy in the form of a plasma of relativistic particles and magnetic fields. The details of the geometry, the polarisation and the spectral index of the emission along the jets will be important in the full understanding of the physical mechanisms in radio galaxies. ☐

Bent DNA

from Michael Spencer

FOR many years after the initial excitement wore off, the devotees of DNA stereochemistry soldiered on with their studies amid some disbelief that the detailed results would be of much interest to those working on biochemical problems. It was an esoteric speciality, occupied with the niceties of sugar ring pucker, base tilt and base twist. All this began to change as biochemists accumulated evidence for non-coding regions of DNA containing special sequences, in particular the promoter region associated with the binding of RNA polymerase. It appeared in this case that the binding caused a localised unwinding of the DNA duplex, and interest grew in discovering exactly what changes in structure were involved. In this way it was hoped to obtain a better understanding of how the enzyme recognised the site and initiated synthesis.

In two other fields DNA deformation became of interest, and models were proposed for a 'kink' involving the unstacking of one base pair relative to an adjacent pair. It seemed a plausible way of explaining the compaction of DNA in the nucleosome (Crick & Klug *Nature* **255**, 530; 1975), though other interpretations were later suggested (see *News and Views*, 1 September 1977). In the field of DNA-drug interactions, it was proposed that intercalation of a drug molecule could occur at sites where a spontaneous kink, induced by a thermal energy fluctuation, allowed the drug to slip in between the base pairs (Sobell *et al. Cold Spring Harbor Symp. quant. Biol.* **42**, 87; 1977). It was further suggested that such a kink might propagate down the polymer in a wave like disturbance.

In all this, it was generally assumed that DNA remained in the well-known *B* conformation that purified material shows in an aqueous environment. However, a few workers always hoped that they would some day find a biological role for the rather different *A* conformation that is often found under conditions of low water content and low ionic strength. This has 11 instead of 10 base pairs per turn, and the bases are tilted and laterally displaced in relation to the helix axis. It has been known since 1962 that RNA had a structure of the *A* type, and the *A* structure received a further boost when it was discovered that DNA-RNA hybrids preferred it. The idea germinated that even if DNA *in vivo* did not adopt an *A* structure along its whole length, there might be local transitions induced by changes of environment or interaction with other, more hydrophobic molecules (Arnott *et al. Nature* **220**, 561; 1968, Florentiev & Ivanov *Nature* **228**, 519; 1970). More recently, Minyat *et al.* (*J. molec. Biol.* **128**, 397; 1978) have obtained evidence from circular dichroism that spermine and spermidine do stabilise the *A* conformation in solution, under conditions of decreased water activity. They deduced that the cooperative unit could be as short as 10 base pairs.

A collaboration between groups at Wisconsin and Purdue (Selsing *et al. J. biol. Chem.* **254**, 5417; 1979) has now led to a convincingly detailed model for a DNA duplex containing an *A* structure at one end and a *B* structure at the other, with a sharp bend in the middle where the conformation changes. Their work follows the synthesis of a model copolymer containing dG along the whole of one strand; the other strand contains a block of rC, giving the *A* structure characteristic of hybrids, linked by T4 DNA ligase to a section of dC, which in solution leads to a *B* structure. Solution studies by Selsing and Wells (*J. biol. Chem.* **254**, 5410; 1979) have confirmed the earlier conclusion from NMR work that the transition region is confined to only one or two base pairs.

The new model-building exercise was carried out for a purely DNA duplex with only a single nucleotide pair in the transition region. In the most satisfactory of the models tested, the transition base pair has one nucleotide with the sugar pucker characteristic of *A*-DNA, and one with the different pucker found in *B*-DNA. The change of conformation leads to a 26° change in the direction of the helix axis, while preserving full base stacking and hydrogen bonding. It may thus be energetically preferable to an unstacked kink. Furthermore, the base stacks predicted at the junction for different DNA sequences have noticeable similarities to those actually found in dinucleotide and polynucleotide structures.

The authors discuss the biological implications with some enthusiasm. Their model gives respectability to the belief that segments of *A*-DNA may be induced to form in an otherwise *B*-DNA helix, and this might well explain the observed unwinding of DNA on binding RNA polymerase. However, they do not go into the question of how the RNA might then be copied; does the helix open up, as originally suggested by Florentiev and Ivanov, or is a triplet structure formed as suggested by Riley (*Nature* **228**, 522; 1970)? Another relevant matter which they do mention is the discovery of alternating A, T-rich and G, C-rich blocks in many regulatory regions. In DNA fibres, the former type of sequence leads to a preference for a *B* conformation, while the latter extends the stability range of the *A*. If these preferences held under cellular conditions (which remains to be proved), the DNA could adopt a tertiary structure determined by the length of the segments. Alternating single turns of each kind of helix, both containing about 10 base pairs, would result in the helix axis following a zigzag path. On the other hand, half a turn of each helix would result in a small loop of DNA, and the authors illustrate a computer-generated model for such a structure.

If such features were stable *in vivo* they might form recognition sites for protein ligands; alternatively, they might be induced to form by the more hydrophobic environment resulting from the presence of protein. It is an intriguing thought that an enzyme working its way down the DNA duplex might trigger off a local change in conformation that stopped it in its tracks. The hunt must now be on for direct evidence of such local changes in structure. The authors point out that a loop containing *A*-DNA segments will contain a distinctly shorter average length per nucleotide than the superficially similar structure obtained by smoothly bending *B*-DNA. This could, they say, explain a

0028-0836/79/430631-02$01.00

recent observation by Griffiths (*Science* **201**, 525; 1978) that electron micrographs of ϕX174 DNA suggest a nucleotide repeat of only 2.9 Å, instead of the 3.4 Å expected for *B*-DNA. The alternative explanation preferred by some workers is the existence in solution of a *B*-like structure with slightly more than 10 residues per turn (Wang *Proc. natn. Acad. Sci. U.S.A.* **76**, 200; 1979).

The authors finish with a flourish of speculation about the possibility of travelling disturbances. The idea that DNA can 'breathe' and develop a travelling region of denaturation is an old one, and the idea of travelling kinks has already been mentioned; it now seems possible that travelling discontinuities between regions of different DNA conformation might be important in biological recognition. The sequence-specific conformational preferences that have been shown for DNA would, they say, act as 'sources, sinks and barriers' for transient conformational discontinuities in the helix. The idea of DNA as an inert repository of genetic information seems really to have breathed its last. □

Locust phase colouration

from Richard J. Moore

CHANGE in colouration is the most noticeable feature of the 'phase' transformation which locusts undergo during their large population fluctuations, yet its adaptive significance has proved one of the most difficult to explain. Individuals in low population densities during plague recessions (*solitaria* phase) are a uniform green, presumably a disguise from the attentions of visually-guided predators. During plague outbreaks, individuals develop a striking black and yellow or orange colouration (*gregaria* phase).

This suggests an aposematic or warning function to predators; yet locusts are voraciously pursued by flocks of birds, and nomads regard them as something of a delicacy. Batesian mimicry of a poisonous or distasteful model is unlikely to be operating since no possible models with a similar range are known, and in any case the vast numbers of locusts in swarms would greatly outnumber any model.

Early research on the problem focused on the possible role of the *gregaria* colour pattern in maintaining migratory groups. In 1928, Boris Uvarov suggested that the increased activity of hoppers (nymphs) in bands resulted from an optomotor or visual compensation response to movement of neighbours. Peggy Ellis (*J. exp. Biol.* **30**, 214; 1953) found, however, that a background of moving vertical stripes was not as effective in maintaining the characteristic 'marching' of hoppers as visual stimuli from moving locusts. This and a more recent experiment by Sylvia Gillett suggests that locust shape is the more important stimulus for grouping. Gillett (*Anim. Behav.* **21**, 153; 1973) mixed normally-pigmented *gregaria* desert locusts with albinos, which aggregate less than coloured individuals. Mixing them neither reduced the grouping of normal locusts, nor increased the grouping of albinos: thus the reduced grouping of albinos alone must be due to some other factor besides lack of colouring.

It should be noted that Gillett's experiment examined static aggregation; and also that the vertical stripes in Ellis's experiment were not specifically designed to imitate *gregaria* locust patterning. So it remains a possibility that the patterning has evolved to maximise the optomotor response, and thus cohesion of moving groups.

Recently, however, workers have begun to examine the role of predation as the evolutionary force promoting phase polymorphism; indeed, aggregation itself may give a defensive advantage against predators. Matthews proposes (*Amer. Nat.* **111**, 213; 1977) that individual locusts, and also Australian stick insects (which undergo remarkably similar density-dependent phase transformations), contain small amounts of toxins, so that the consumption of large numbers of them by a predator would eventually exceed its tolerance limit. Remembrance of the strikingly-coloured prey which had produced the intoxication would result in a specific avoidance image (a negative 'search image') preventing further consumption of locusts. It is doubtful, though, how much protection would be conferred in this way, since large birds such as storks are known to be capable of consuming in the order of 1000 adult locusts per day, day after day.

Gillett has begun to look at the factors affecting locusts' vulnerability to predation. Against a green irregular background, surprisingly, *gregaria* nymphs are just as effectively camouflaged as *solitaria* (Gillett & Gonta *Anim. Behav*, **26**, 282; 1978). But in a strategy of crypsis, density is also of major importance, as her experiments showed. In the wild, *gregaria* nymphs often occur massed in numbers so great as to preempt any possibility of escaping detection. These very numbers, and their increased activity, might make it difficult for a predator to pick off individual locusts. Could the *gregaria* pattern contribute to this?

In her latest work (Gillett, Hogarth & Noble, *Anim. Behav.* **27**, 592; 1979), Gillett and her coworkers offered *gregaria* desert locusts at a range of densities to a lizard and human predators in an otherwise empty arena. The catching efficiency of the human predators did not vary much, but the effect of increasing prey density on the lizard's catching efficiency was dramatic: above a certain prey density, the lizard became totally incapable of catching any locusts. Gillett *et al.* attribute these results to a 'visual confusion effect' produced by the activity of the locusts — an effect which, they suggest, would be enhanced by the bold patterning. This remains to be demonstrated, but there are strong indications of the importance of prey-striping in other predator — prey interaction (see, for instance, the discussion in Milinski, *Z. Tierpsychol.*, **45**, 373; 1977).

Although this is an attractive hypothesis, it may still not be the whole story. There is no reason why the *gregaria* colour pattern should not have multiple functions, but it is remarkable that neither of the most likely functions in locusts — group cohesion and predator confusion — could be of any use to Australian stick insects: they do not aggregate, and even at high densities, are very inactive. □

Richard Moore is a member of the Cambridge C.S. Research Group, a contract research organisation specialising in tropical marine conservation.

New human myeloid leukaemia cell line undergoes red shift

from P.R. Harrison

BIOLOGISTS interested in elucidating how cells acquire their specialised functions (the process of cell differentiation) are always on the look out for ways in which these normal developmental processes can be mimicked by *in vitro* systems as these often allow the design of more sophisticated experimental approaches than are normally possible *in vivo*. This applies with even greater force of course to experiments with human cells. For a long time, cells from leukaemic patients or animals have provided useful models for how cells grow and differentiate and the relationship between the occurrence of malignancy and consequent abnormal cell growth and differentiation.

Recently a new human cell line has made something of an impact in the literature on account of its very interesting properties. The K562 cell line was established several years ago by Lozzio and Lozzio working at the University of Tennessee from the pleural effusion of a patient with chronic myeloid leukaemia (CML) in terminal blast crisis (*Blood* **45**, 321; 1975). Initially it was assumed, largely on morphological criteria, that the K562 cells were derived from the outgrowth of a malignant clone of myeloid leukaemic cells arrested at some very early stage of granulocyte

---

P. R. Harrison is at the Beatson Institute for Cancer Research, Glasgow.

differentiation. By analogy with the now classic experiments in which mouse erythropoietic cell precursors infected with Friend virus can be induced to differentiate further by treatment with DMSO and other chemicals (Friend *et al. Proc. natn. Acad. Sci. U.S.A.* **68,** 378; 1971). Lozzio's group tested the effect of DMSO on the human K562 cell line but could find no evidence of enhanced differentiation (Bamberger *et al. Leukemia Res.* **2,** 305; 1978).

But this year the situation has changed dramatically with a series of recent reports. First, Anderson and his colleagues at the University of Helsinki found to their surprise that in fact the surface properties of the K562 cell line resembled red blood cells rather than granulocytes or their benign or leukaemic precursors and in particular K562 cells were found to synthesise a highly specific red blood cell membrane protein, glycophorin (*Int. J. Cancer* **23,** 143; 1979; *Nature,* **279,** 498; 1979). Further support for the idea that K562 cells are in fact erythroid precursor cells comes from the subsequent finding by Anderson and his colleagues that sodium butyrate can induce erythroid maturation in K562 cells as judged by the formation of erythrocyte-like particles and haemoglobin, assayed either by benzidine staining or immunologically (*Nature* **278,** 364; 1979). This conclusion has recently been taken one important and very interesting step forward by Rutherford and his colleagues in Oxford who have reported that haemin induces human embryonic haemoglobin in K562 cells, as judged by starch gel electrophoresis and comparison of fingerprints of tryptic peptides with those from authentic human embryonic haemoglobins (*Nature* **280,** 164; 1979).

Whether other inducers (for example, butyrate in the experiments of Anderson *et al.*) induce embryonic or adult haemoglobin in K562 cells is not yet clear. There is some precedent for this in the Friend cell where haemin induces preferentially a minor ß-globin chain, rather than the usual major ß-globin chain (Rovera *et al. FEBS Lett.* **81,** 366; 1977; Nudel *et al. Proc. natn. Acad. Sci. U.S.A.* **74,** 1100; 1977). Certainly, if different inducers were to induce different globin chains, then the K562 cell would provide an extremely interesting system for studying the embryonic to adult globin gene switch *in vitro.*

Nevertheless, the originators of the K562 cell line are evidently still not at all happy with this accumulated evidence for its erythroid nature since they cannot reproduce the induction of haemoglobin in their own original stocks of K562 cells by sodium butyrate which in their hands is merely cytotoxic (Lozzio *et al. Nature,* **281,** 709; 1979). Perhaps this is not too surprising since Rutherford *et al.* (*op. cit.*) found haemin to be the only effective inducer of K562 cells, butyric acid and other Friend cell inducers tested being ineffective at the concentrations normally used. But those familiar with the Friend cell field will not be too perturbed at these differences between the laboratories concerning which inducers are most effective, since precise inducer concentrations and other variables in the culture conditions are often important. For example the batches of serum used, particularly in experiments where butyric acid is used as inducer, can affect the outcome. In any event, Lozzio *et al.*'s suggestion that the cells used by Anderson *et al.* (and presumably also Rutherford *et al.*) may have been contaminated with other cells with erythroid properties (a claim hotly and justly denied by Anderson *et al.* on the basis of karyotype evidence — *Nature,* **281,** 710; 1979) seems to me to be an inadequate explanation. Whether Anderson's karyotypically-authentic K562 line might have acquired its erythroid properties during clonal evolution in culture rather than *in vivo* is more difficult to resolve.

What then is the significance of the K562 cell line for the future? Is it a matter of *déjà vu* and essentially a repeat of the Friend cell story in a human context? Not simply. The isolation of human leukaemic cell lines other than those derived from lymphoid precursors is relatively rare and therefore interesting especially when an adult cell can be induced to produce embryonic-type proteins. Since embryonic haemoglobins have not been found in association with CML the controversial origin of the cell is clearly of some considerable interest *per se.* Further, the existence of cell lines producing embryonic and adult globins (the K562 and Friend cells respectively) may allow the differential regulation of the embryonic and adult globins to be studied more thoroughly, for example, possibly by exploiting the effects of different chemical inducers or by cell fusion studies. And undoubtedly the K562 cell line will be exploited simply because it is a human erythroid cell line, for example it can be used for studies of the properties of human red blood cell precursors and as a source of embryonic globins and other red blood cell proteins. ☐

Pituitary growth hormone

from Mike Wallis

THE pituitary growth hormones (GHs) together with the prolactins and placental lactogens comprise a family of protein hormones which regulate somatic growth, lactation and various other biological functions. An international symposium on GH and related hormones is held at four-yearly intervals in Milan; the most recent one* was broadened to include 'Other Biologically Active Peptides' though fortunately this was not taken too literally, and GH and its relatives remained the main focus of attention (and will be the only topic considered here).

As in many other areas of biology, recombinant DNA technology is making a major impact on polypeptide hormone biochemistry. H.M. Goodman (University of California, San Francisco) described the cloning and characterisation of the gene for human GH. The gene includes at least two introns, and some evidence suggests that several slightly different (non-allelic) copies of the GH gene may exist in the human genome. The nucleotide sequence of the (cloned) cDNA has been determined, including the entire coding region for the preGH. Expression of immunologically active human preGH (as a fusion protein including part of the bacterial trpD gene product) has been achieved in *E.coli* and the production of substantial quantities of human GH by genetic engineering in bacteria must now be imminent. The timing is appropriate since the hormone may well have new clinical uses (in addition to treatment of hypopituitary dwarfism); V. Zumtobel *et al.* (University of Munich) described applications of the hormone in the treatment of stress ulcers.

Another technique with great potential was described by J. Ivanyi (Wellcome Research Institute, Beckenham, UK) who reported the preparation and application of monoclonal antibodies to human GH. At least two antigenic sites can be recognised on human GH, only one of which is shared with human placental lactogen. This powerful technique should provide both specific probes for investigating structure-function relationships and reagents with increased specificity for radioimmunoassay.

Lack of detailed information about the three-dimensional structure of any member of the GH-prolactin family is a major drawback in understanding their biochemistry. The main problem is lack of suitable crystals for crystallography, and the reasons for this were discussed by K. Moffat (Cornell University). Crystals of human placental lactogen have been obtained but were insufficiently ordered for X-ray analysis. Heterogeneity of the hormone preparations that have been used for crystallisation attempts is a major problem, and Moffat urged those present to try and purify further, and to crystallise,

*An international symposium on 'Growth Hormone and other Biologically Active Peptides' was held in Milan on 17-19 September. The meeting was organised by A. Pecile, E.E. Muller and M.L. Pecile and the Chairman was C.H. Li. Abstracts have been published (*Ricerca Scientifica ed Educazione Permanente* Supplement 11) and invited papers will be published in full by *Excerpta Medica.*

0028-0836/79/430633-02$01.00

their favourite hormones.

In the absence of information about three-dimensional structure, knowledge about structure-function relationships must come from other sources. Species specificity is marked among the GHs (thus, non-primate growth hormones are not active in man) and comparisons of GHs from different species may eventually provide clues to structure-function relationships. Purification and characterisation of GHs from various lower vertebrates was described by H. Papkoff *et al.* (University of California, San Francisco). Immunological and physicochemical differences between the hormones mainly reflect the extent of phylogenetic divergence, but biological activities are rather variable and do not follow phylogenetic relationships so closely. Sequence information for these proteins is eagerly awaited, but for the present our knowledge of the molecular evolution of this protein family remains based largely on the sequences of mammalian hormones. Studies on chemically modified forms of GH, and on synthetic fragments, may also help relate structure to function, and were described by A.C. Paladini *et al.* (University of Buenos Aires) who are attempting to define precisely which residues are required for activity. At least one antigenic site has been tentatively identified as associated with a region of 30–50 amino acid residues long, near the centre of the primary structure.

The mechanism of action of GH remains unclear. In particular it remains uncertain (and a matter of considerable controversy) as to which of the actions of the hormone are direct and which are mediated by somatomedins. Like other polypeptide hormones, GH is thought to bind initially to a membrane receptor, and the nature and characterisation of receptors was discussed in several papers. Direct actions of the hormone on erythroid colony formation *in vitro* were described by D.W. Golde (University of California, Los Angeles) and direct actions on amino acid uptake and incorporation by diaphragm *in vitro* were discussed by K. Albertsson-Wikland, A. Lindahl and their colleagues (University of Göteborg).

However, most of the discussion about the actions of GH centred on the somatomedins and their role in mediating these actions. Various forms of somatomedin have been described, at least some of which are very similar to the insulin-like growth factors IGF 1 and IGF 2, which have now been quite well characterised and which were discussed by J. Zapf and E.R. Froesch (University Hospital, Zurich). J.J. Van Wyk *et al.* (University of North Carolina) described studies on the characterisation of human somatomedin C, including determination of a partial amino acid sequence; the hormone is similar to IGF 1. Somatomedin C stimulates growth of various types of cell *in vitro* and was also shown to have *in vivo* actions on the frog lens epithelium. Studies on somatomedin A were described by A. Skottner *et al.* (A.B. Kabi, Stockholm) though amino acid sequence data are still not available for this hormone, and its relationship to the IGFs is uncertain. Somatomedin B, is now thought to be without somatomedin-like properties, and therefore inappropriately named. Although somatomedins A and C are thought to mediate at least some of the actions of GH, and although they have many biological effects *in vitro*, attempts to show GH-like actions of somatomedins *in vivo* have previously met with little success. However, J.V.L. van den Brande, S.C. van Buul-Offers and their colleagues (Wilhelmina Children's Hospital, Utrecht) reported that clear-cut growth hormone-like effects (including increase in body weight and length) have now been obtained when human somatomedins were injected into hypopituitary dwarf mice. Somatomedins are thought to be produced in the liver in response to stimulation by GH and other factors. Studies on the biosynthesis of somatomedin in cultured Buffalo Rat Liver cells were described by S.D. Schalch *et al.* (University of Colorado) who presented evidence for a precursor of the hormone of molecular weight about 32,000. Other hepatocyte systems which produce somatomedins (and also their binding proteins) were also described (G. Haselbacher *et al.*, University of Zurich; M. Binoux *et al.*, Trousseau Hospital, Paris); stimulation of somatomedin synthesis by GH was claimed. ☐

The physics of biology

from H. Eisenberg

THE business-like mood at EMBL's Hamburg laboratory at the DESY synchrotron installation was a welcome change from the *fin-de-siècle* recreational workshop atmosphere one sometimes encounters at fashionable watering places. At the recent EMBO-EMBL workshop* held there, hope, progress, expectation, and fulfilment in the biological applications of neutron and X-ray scattering, in particular with synchrotron radiation, were discussed in depth.

The ILL neutron reactor in Grenoble has now been active for several years and an EMBL outstation, to provide the infrastructure for experiments in biology, was established some years ago. Synchrotron radiation provides information additional and complementary to the neutron scattering and, in particular, the high intensity and pulsed nature of the beam presents unique opportunities. The EMBL laboratory in Hamburg, directed by Heinrich Stuhrmann, has made great strides in the continuing development of suitable facilities to explore these opportunities. Also, construction of new facilities for chemistry and biology at the DORIS storage ring in Hamburg is now underway and, in large measure, success will depend on the concomitant development of appropriate two-dimensional fast detector systems.

Sessions at the workshop reflected the varied interests of the workers involved. Muscle and collagen are two systems long studied by both X rays and neutron fibre diffraction. In particular, hope was expressed that considerable reduction of data collection time into the millisecond range, in the case of synchrotron radiation, will enable performance of dynamic studies and characterisation of individual states in the contractile systems. In solution studies a major tool is the application of contrast variation, particularly favoured by the dramatic difference in neutron scattering between hydrogen and deuterium (with little change in structural or functional properties); complementary information is provided in the case of X-ray scattering by the use of the more classical contrast variation media such as sucrose or salts. These and other theoretical aspects were discussed, as well as the possibility of obtaining information-rich three-dimensional reconstructions from the analysis of spatial fluctuations from random systems. This should be useful for complex biological systems which have not been obtained in crystalline organised form, useful for X-ray diffraction. Problems related to anomalous scattering were also discussed.

Protein–nucleic acid interactions were discussed in sessions devoted to progress in the study of ribosomes, chromatin and viruses. In chromatin we are gaining more understanding on the higher order structures of solutions of finite chains of nucleosomes in a variety of experimental conditions. Additional major topics of discussion involved membranes and lipoprotein complexes, as well as proteins and protein assembly complexes, such as microtubule structure.

The close encounter between about eighty molecular biologists, theoreticians and instrumentalists led to a frank exchange of ideas, created new and extended existing paths of communication in a field of great topical interest.

Distortions of the cosmic microwave background spectrum by dust

M. Rowan-Robinson*†, J. Negroponte† & Joseph Silk†

* Queen Mary College, London E1, UK
† University of California, Berkeley, California 94720

The cosmic microwave background spectrum supports the idea of a pre-galactic generation of stars. The distortions of the background spectrum from a black body can be due to emission by dust if a modest fraction of the mean cosmological density is present as silicate particles at epochs corresponding to redshift $z \gtrsim 100$. Whether the entire background can be explained as emission from dust is investigated.

IN the standard hot big bang cosmology, the Jeans mass at the epoch of decoupling of matter and radiation ($z \sim 1,000$) is about $10^6\,M_\odot$, so that any strong density perturbations present on this scale would collapse rapidly, in $\sim 10^6[(1+z)/1,000]^{3/2}$ yr. Dicke and Peebles[1] proposed that globular clusters might have formed in this way before galaxies did. White and Rees[2] suggested a more radical version of this idea, in which an early generation of stars, perhaps formed by these $10^6\,M_\odot$ objects, evolved rapidly to form dark remnants (presumably black holes or stars of very low mass) and now comprise the 'missing mass' postulated to bind clusters of galaxies and to make up haloes around massive spiral galaxies[3]. The concept of a pre-galactic generation of stars, often referred to as 'Population III', was taken further by Rees[4], who suggested that the cosmic microwave background radiation could be the light from such stars absorbed and re-thermalised by dust grains, molecules or ionised gas. Various earlier schemes[5-13] for a non-cosmological origin of the cosmic background radiation have encountered difficulties, because of the severe requirements of energetics and thermalisation. The hypothesis of Rees minimises these problems, and may lead to an explanation of the observed average number of photons per baryon in the Universe, an unexplained constant ($\sim 10^9$) in the standard big bang models.

The effect of dust in the early Universe

We investigate here the effect of dust in the early Universe on the cosmic microwave background, including the effect of a pre-galactic Population III generation of stars. We assume that at epochs such that $z \gg 100$, the cosmic background has a black-body spectrum of temperature $T_r = T_0(1+z)$. In Rees' model[4], $T_0 \ll 3$ K, but in more conventional models $T_0 \sim 2.7$–3.0 K. Suppose that at an early epoch a generation of stars is born that live for a time t_s, dying at epoch t_f, where $t_s \ll t_f$.

Let ε be the efficiency with which the matter in the Universe is converted into radiation by this Population III. If most of the matter in the Universe forms into Population III objects and undergoes conversion to helium and heavy elements, then ε can be as high as ~ 0.01. If most of the energy is generated by accretion of material onto black holes, then ε could be as large as 0.1–0.3. Conventional models for quasars evidently require such a high efficiency[14].

Assuming the Population III objects radiate as black bodies with temperature T_s, radius r_s, and have number density η_s at epoch t_f, then

$$\varepsilon\rho_m(t_f)c^2 = 4\pi r_s^2 \eta_s \sigma T_s^4 t_s \qquad (1)$$

where $\rho_m(t)$ is the matter-density at epoch t.

The energy-density in radiation is enhanced by this radiation input by a factor

$$\begin{aligned}\beta &= \frac{\varepsilon\rho_m(t_f)c^2}{aT_0^4(1+z_f)^4} = \frac{\varepsilon\rho_m(t_0)c^2}{aT_0^4(1+z_f)} \\ &= 420\varepsilon\Omega h^2[100/(1+z_f)](2.7/T_0)^4\end{aligned} \qquad (2)$$

where Ω is the cosmological density parameter, and h is the Hubble constant (units of 100 km s^{-1} kpc^{-1}).

Suppose that these stars give rise at their death to a heavy element abundance Z throughout the remaining gas in the form of dust. Presumably $Z < 10^{-3}$ for consistency with the lowest values found in extreme Population II (ref. 15). If the dust is uniformly distributed, the resulting optical depth at epoch t_1 to a source emitting at epoch t_2,

$$\tau_\nu(t_2, t_1) = \pi a^2 c \int_{t_2}^{t_1} n_g(s) Q_{\nu(1+z)}\, ds \qquad (3)$$

where $n_g(t)$ is the number-density of grains at epoch t, and $1+z = R(t_1)/R(s)$. Thus

$$\tau_\nu(t_2, t_1) = A \int_{t_2}^{t_1} Q_{\nu(1+z)}[R_0/R(s)]^3\, ds/t_H$$

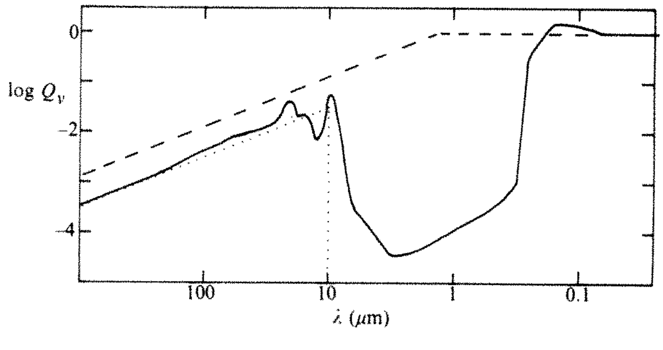

Fig. 1 Dust absorption efficiency used in this work. Solid line, amorphous silicates; dotted line, analytic approximation to these (equation (15)); dashed line, equation (14).

0028–0836/79/430635—04$01.00

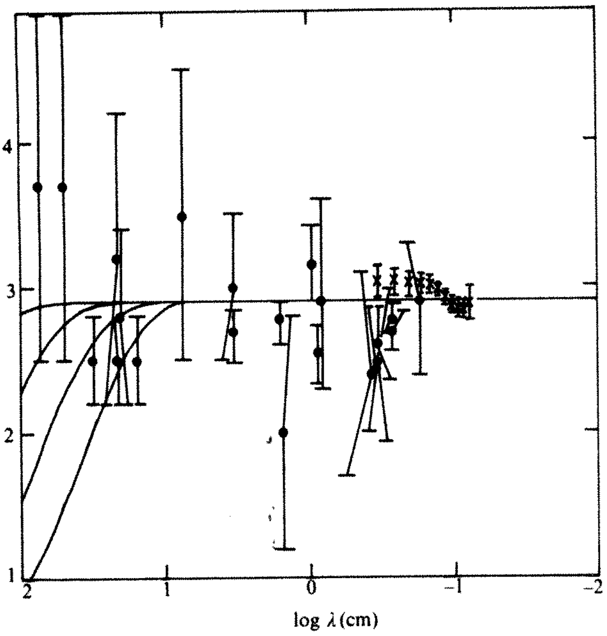

Fig. 2 Observed microwave background spectrum (●, from Danese and de Zotti[13]; ×, from Woody and Richards[20]), plotted as thermodynamic temperature, $T_{\rm th}$, against wavelength, compared with predictions for grains with Q_ν given by equation (14), $T_{\rm d}=2.9$, $T_0=0$, $1+z_{\rm f}=200$ and (from the top) $qZ=10^{-2}$, 4×10^{-3}, 2×10^{-3}, 10^{-3}.

where $A=\pi a^2 n_{\rm g}(t_0)ct_{\rm H}$, Q_ν is the absorption efficiency of the grains (as the radiation field in this problem is always isotropic, scattering can be entirely neglected), $R_0=R(t_0)$, and $t_{\rm H}$ is the Hubble time at the present epoch t_0.

In terms of Ω,

$$A=5.1\,\Omega h\,(Z/0.001)(0.1\,\mu{\rm m}/a)(2.5\,{\rm g\,cm^{-3}}/\bar\rho_{\rm g}) \tag{4}$$

where a is the grain radius, and $\bar\rho_{\rm g}$ is the mean density of the grain material.

If $T_{\rm d}(t)$ is the temperature of the dust grains at epoch t, the intensity of radiation observed at epoch $t>t_{\rm f}$ is the sum of the contributions from the cosmic background and Population III, attenuated by dust, and from the emission by dust:

$$\begin{aligned}I_\nu(t)=\{&(1+z_{\rm r}')^{-3}B_{\nu(1+z_{\rm r}')}[T_{\rm r}(t)]\\&+(1+z_{\rm f}')^{-3}\pi\eta_{\rm s}r_{\rm s}^2ct_{\rm s}B_{\nu(1+z_{\rm f}')}(T_{\rm s}\}\exp\left(-\tau_\nu(t_{\rm f},t)\right)\\&+\int_{t_{\rm f}}^{t}(1+z')^{-3}B_{\nu(1+z')}[T_{\rm d}(s)]\exp-\tau_\nu(s,t)\,{\rm d}\tau_\nu(s,t)\\&\qquad\qquad{\rm erg\,cm^{-2}\,s^{-1}\,H^{-1}}\end{aligned}$$

where $1+z_{\rm r}'=R(t)/R(t_{\rm r})$, $1+z_{\rm f}'=R(t)/R(t_{\rm f})$, $1+z'=R(t)/R(s)$. This can be written:

$$\begin{aligned}I_\nu(t)=\{&B[T_0(1+z)]+\pi\eta_{\rm s}r_{\rm s}^2ct_{\rm s}B_\nu[T_{\rm s}/(1+z_{\rm f}')]\}\\&\times\exp-\tau_\nu(t_{\rm f},t)\\&+\int_{t_{\rm f}}^{t}B_\nu[T_{\rm d}(s)/(1+z')]\exp-\tau_\nu(s,t)\,{\rm d}\tau_\nu(s,t)\end{aligned} \tag{5}$$

where $1+z=R_0/R(t)$.

The equation of radiative balance for the grains takes the form

$$\int_0^\infty Q_\nu B_\nu[T_{\rm d}(t)]\,{\rm d}\omega=\int_0^\infty Q_\nu I_\nu(t)\,{\rm d}\nu \tag{6}$$

In particular, at $t_{\rm f}$ equation (6) becomes

$$\begin{aligned}\int_0^\infty Q_\nu B_\nu[T_{\rm d}(t_{\rm f})]\,{\rm d}\nu=&\int_0^\infty Q_\nu B_\nu[T_0(1+z_{\rm f})]\,{\rm d}\nu\\&+\pi\eta_{\rm s}r_{\rm s}^2ct_{\rm s}\int_0^\infty Q_\nu B_\nu(T_{\rm s})\,{\rm d}\nu\end{aligned} \tag{7}$$

As $T_{\rm d}(t_{\rm f})\leqslant T_{\rm m}$, the melting temperature of the grains, equation (7) implies

$$\pi\eta_{\rm s}r_{\rm s}^2ct_{\rm s}\int_0^\infty Q_\nu B_\nu(T_{\rm s})\,{\rm d}\nu<\int_0^\infty Q_\nu B_\nu(T_{\rm m})\,{\rm d}\nu \tag{8}$$

Assuming the stars radiate in the UV (for example, 0 stars with $T_{\rm s}\sim40{,}000$ K) so Q_ν can be set equal to unity on the left hand side, equation (8) is equivalent to a limit on the product $\beta(1+z)^4$. If we set $Q_\nu=2x$, $x=2\pi a/\lambda$, we find $\beta(1+z_{\rm f})^4<10^{10.65}(T_{\rm m}/1{,}500)^5$. If $\beta=1$, as in Rees' model[4], $(1+z_{\rm f})<400$. Before this epoch grains could not survive. For silicate grains, the limit is more severe, $1+z_{\rm f}<10^{2.03}\,\beta^{-1/4}$ for $T_{\rm m}=1{,}500$ K.

High optical depth limit

Suppose that at the present epoch, the optical depth in dust is large at all wavelengths ⩽20 cm, say. Then the contribution of the first two terms on the right hand side of equation (5) to the integral on the right hand side of equation (6) is negligible, and the solution of equation (6) is

$$T_{\rm d}(t)=T_{\rm d}(t_0)(1+z),\qquad t\gg t_{\rm f} \tag{9}$$

The observed intensity at the present epoch in the microwave range would be

$$\begin{aligned}I_\nu(t_0)=B_\nu(T_0)\exp-\tau_\nu(t_{\rm f},t_0)+B_\nu[T_{\rm d}(t_0)]\\\times[1-\exp-\tau_\nu(t_{\rm f},t_0)]\end{aligned} \tag{10}$$

To determine $T_{\rm d}(t_0)$, we note that the conservation of co-moving energy density implies that

$$T_{\rm d}(t_0)^4\simeq T_0^4(1+\beta) \tag{11}$$

In particular if there were no radiation from stars ($\beta=0$), then $T_{\rm d}(t_0)=T_0$, and $I_\nu=B_\nu(T_0)$, so that there is no distortion from a black-body spectrum. Equation (9) may not be a bad assumption where the optical depth in the UV is high, but that in the microwave region is ⩽1. This is because although $T_{\rm d}(t_{\rm f})\gg T_0(1+z_{\rm f})$ in general, the temperature subsequently drops rapidly with time as $\tau_{\rm UV}(t_{\rm f},t)$ increases, until it is of the form of equation (9). However, in this case equation (11) should be replaced by

$$T_{\rm d}(t_0)^4[1-\exp-\tau_{\nu(T_0)}]\simeq T_0^4\,[1-\exp-\tau_{\nu(T_0)}+\beta) \tag{12}$$

where $\tau_{\nu(T)}$ is the optical depth back to $t_{\rm f}$ at the frequency corresponding to the peak of a Planck spectrum with temperature T. Thus if $T_{\rm d}(t_0)=T_0(1+\delta)$

$$1+\delta\simeq[1+\beta/(1-\exp-\tau_{\nu(T_0)})]^{1/4} \tag{13}$$

For $1+z_{\rm f}=200$, $T_0=2.7$, $\beta=0.25$ (for $\varepsilon=0.01$, this means $\Omega h^2=0.12$), $\tau_{\nu(T_0)}\sim1$, then $T_{\rm d}(t_0)=3.0$ K.

Assumptions about grain properties

The absorption efficiency in the IR of interstellar grains in the solar neighbourhood is not well known, so the properties of the

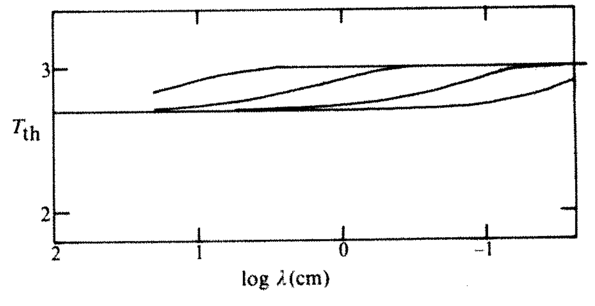

Fig. 3 $T_{\rm th}$ against λ for grains with Q_ν given by equation (14), $T_{\rm d}=3.0$, $T_0=2.7$, $1+z_{\rm f}=100$, and (from the top) $qZ=10^{-3}$, 10^{-4}, 10^{-5}, 10^{-6}.

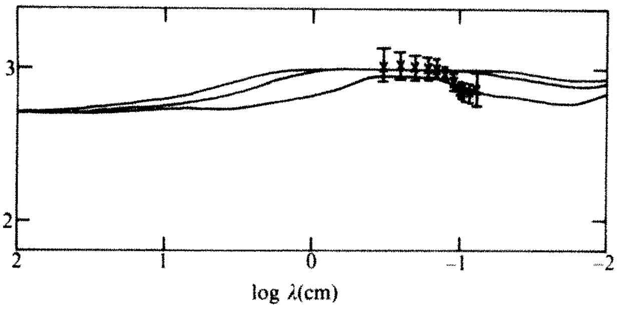

Fig. 4 T_{th} against λ for amorphous silicate grains, $T_d = 3.0$, $T_0 = 2.7$, $1 + z_f = 200$, and (from the bottom) $Z = 10^{-5}$, 5×10^{-5}, 10^{-4}, compared with Woody and Richards rates.

postulated grains in the early Universe can only be speculative. We have investigated three assumptions about Q_ν:

$$\begin{aligned} \text{(a)}\quad Q_\nu &= qx,\ x = 2\pi a/\lambda < 1/q \\ &= 1,\ x \geq 1/q,\ \text{where } q \leq 2 \end{aligned} \tag{14}$$

With $q = 2$ this represents the theoretical maximum efficiency for grains[17]. It has been argued[16] that in the far IR, grains in hot-centred molecular clouds have $q \sim 0.1$ for $a = 0.1$ μm.

(b) Amorphous silicate grains, for which we have calculated the absorption efficiency in the range 9–200 μm from the data of Day[18], used the Q_ν for terrestrial silicates given by Aannestad[19] for $\lambda < 9$ μm, and extrapolated assuming $Q_\nu \propto \nu$ for $\lambda > 200$ μm (see Fig. 1).

(c) An analytical approximation to the Q_ν for amorphous silicates, suitable for our purposes, given by

$$\begin{aligned} Q &= 0.5\,x, & \lambda &\geq 10\ \mu\text{m} \\ &= 0, & 10\ \mu\text{m} &> \lambda > 2\pi a \\ &= 1, & \lambda &< 2\pi a \end{aligned} \tag{15}$$

We have evaluated equation (10) for these types of grain with various assumptions about T_0, $T_d(t_0)$ and A (or Z). We are interested in two cases in particular: first, Rees' model[4] to explain the whole microwave background radiation from grains; and second, the spectrum observed in the millimetre and submillimetre range by Woody and Richards[20], which seems to show a significant distortion from a Planck spectrum.

We have plotted the results in the form of the thermodynamic temperature T_{th} as a function of ν, defined by $I_\nu = B_\nu(T_{\text{th}})$. Figure 2 shows models with $T_0 = 0$, $T_d(t_0) = 2.9$, for absorption efficiencies of the form of equation (14), with various values of qZ, and with $1 + z_f = 200$, compared with observations. As $q \leq 2$ (ref. 17), and in practice probably $q \leq 0.5$ (see ref. 19 and assumption (b) above), we see that the value of Z needed to fit the observations at long wavelengths is higher than that estimated by Rees[4]. We find $Z \geq 0.001$, and this exceeds the metal abundance seen in some globular clusters in our Galaxy[15]. This would imply that the matter which was to form into galaxies had to remain relatively unpolluted by the heavy elements made by Population III, an artificial situation. It is possible that some other material can be found to fill in the opacity at long wavelengths, for example, redshifted molecular lines. However, this model also fails to explain the distortion seen by Woody and Richards[20].

Figure 3 shows models with $T_0 = 2.7$, $T_d(t_0) = 3.0$, and grains of the form of equation (14) with various values of qZ, for $(1 + z_f) = 100$. Rather like the distortions caused by the effect of Compton scattering on heat input before decoupling[21], we see a gradual changeover from $T_{\text{th}} = 2.7$ at long wavelengths to $T_{\text{th}} = 3.0$ at short wavelengths. This does not correspond with what is observed.

Figure 4 shows a range of models with amorphous silicate grains and $T_0 = 2.7$, $T_d(t_0) = 3.0$, $1 + z_f = 200$. The distortions from a black-body spectrum are rather similar to those observed if $Z \sim 10^{-5}$. Figure 5 shows a range of models for grains with Q_ν of the form of equation (15) and $1 \geqq z_f = 100$, 200, 500 (the latter case is implausible by equation (8)). The analytical approximation gives results very similar to those for amorphous silicates. The crucial requirement in explaining a distortion of the type seen by Woody and Richards[20] is the sudden drop in absorption efficiency at wavelengths <10 μm. The redshifting of this drop in opacity into the millimetre range can give the observed distortions. None of the classical pre-decoupling distortions that have been predicted[21] can account for these distortions. No other grain material shows this phenomenon as strongly as silicates.

Conclusions

The Rees model comes close to fitting the whole background spectrum but seems to be in trouble at wavelengths ≥20 cm if we are restrained to plausible values of the metal abundance at early epochs. It also fails to fit the Woody and Richards[20] data, as does the classical big bang picture with or without heat input before the decoupling era.

If the Woody and Richards spectrum is taken seriously, it can be explained as being due to emission by silicate dust at early epochs. The required metal abundance is rather low, $\sim 10^{-5}$ by mass, and is consistent with limits obtained from the absence of reddening or a 2,200 Å absorption feature in the spectra of most quasars[22]. The energy input needed to distort the spectrum so drastically is substantial, requiring most of the matter in a Universe with the closure density ($\Omega = 1$) to undergo thermonuclear reactions in Population III. There are essentially no free parameters in our model because although any $z_f \geq 100$ would give the observed distortion, the grains would be melted at epochs such that $z_f \geq 200$. For the same reason the black-body spectrum that we assume to be present at epochs such that $z \gg 100$ could not be the result of some earlier thermalisation by dust (say of radiation from black holes in the cold universe of Carr[23] or the tepid universe of Carr and Rees[24]).

We have not attempted to give any astrophysical details of the proposed Population III, as these details are not likely to be observable. One obvious requirement is that the dust be spread sufficiently homogeneously to be consistent with the small-scale isotropy of the background. As the dust has a strong effect only at $\lambda \sim 1$–3 mm, this is not a very severe requirement at present. A search for small-scale structure in the millimetere background

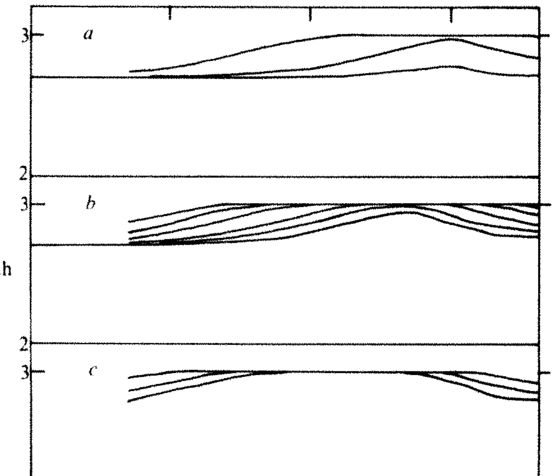

Fig. 5 T_{th} against λ for grains with Q_ν given by equation (15), $T_d = 3.0$, $T_0 = 2.7$; *a*, $1 + z_f = 100$ and (from the bottom) $qZ = 2 \times 10^{-6}$, 2×10^{-5}, 2×10^{-4}; *b*, $1 + z_f = 200$ and (from the bottom) $qZ = 5 \times 10^{-6}$, 10^{-5}, 2×10^{-5}, 5×10^{-5}, 10^{-4} and 2×10^{4}; *c*, $1 + z_f = 500$ and (from the bottom) $qZ = 10^{-5}$, 2×10^{-5}, 5×10^{-5}.

could provide an important constraint for this type of model. The ideas presented here can be tested by accurate measurements of the background spectrum both near the peak and at longer wavelengths. Improved measurements at wavelengths ≥20 cm would be a good test of models which seek to explain the whole background as thermalisation by dust or molecules (and also, incidentally, of distortion due to heat input at very early pre-recombination epochs). We are working on the exact solution of equations (5) and (6) to check assumption (9). The preliminary result is that equation (9) is valid except for redshifts very close to z_t.

The lithology and age distribution of a seismic unit characterised by landward dipping reflectors suggest progressive underthrusting and uplift of trench deposits along the inner slope of the Middle America Trench. The fastest uplift and deformation rates, and the most rapid change in tilt of dipping reflectors coincide near the base of the trench slope and diminish rapidly landwards.

PLATE tectonic theory as well as observations at convergent margins have produced several models of trench slopes each making specific predictions as to the origin, age sequence, and structural configuration of the rocks incorporated therein[1–8]. Off-scraped deep-sea rocks arranged in an imbricate stack of landward dipping thrust slices constitute a popular trench–slope model[1,2] which has been applied widely to both modern subduction zones and their supposed ancient equivalents. This imbricate thrusting model is based primarily on seismic reflection data[2] but is poorly substantiated by drilling.

Thick slope aprons and deep water have hindered sampling of inferred off-scraped deposits by drilling in the Marianas and Japan trenches[6,7,9]. Recovery of inferred off-scraped deposits elsewhere has been limited to restricted areas along a given trench slope and has not provided the data necessary to constrain models of trench–slope evolution[10–12]. Off southern Mexico the lower slope of the Middle America Trench is covered by a thin slope apron overlying a zone of landward dipping reflectors[13] similar to those which elsewhere are considered to constitute off-scraped deep-sea deposits. In this area, the shallow trench and a thin slope apron permitted drilling of three holes into the zone of landward dipping reflectors which provided substantial data on trench–slope evolution. The drilling was conducted during Leg 66 of the Deep Sea Drilling Project (DSDP).

In the Leg 66 area (Fig. 1) the Middle America Trench is characterised by a narrow shelf, steep inner slope and no forearc basin. Our drilling results confirm previous magnetic[14] and seismic reflection[13] studies indicating that the Mesozoic to Precambrian crystalline basement approaches within 35 km of the trench axis which severely limits the width and volume of off-scraped material. This limited accretionary zone probably developed during the Neogene synchronously with magmatism in the Trans-Mexican belt to the north-east. A more extensive Mesozoic and Palaeogene forearc and accreted zone may have been previously removed[14].

Leg 66 drilling results

On Leg 66 DSDP we drilled eight sites (Fig. 1) five of which (Sites 486–488, 491, and 492) are specifically relevant to trench–slope models.

0028–0836/79/430638—05$01.00

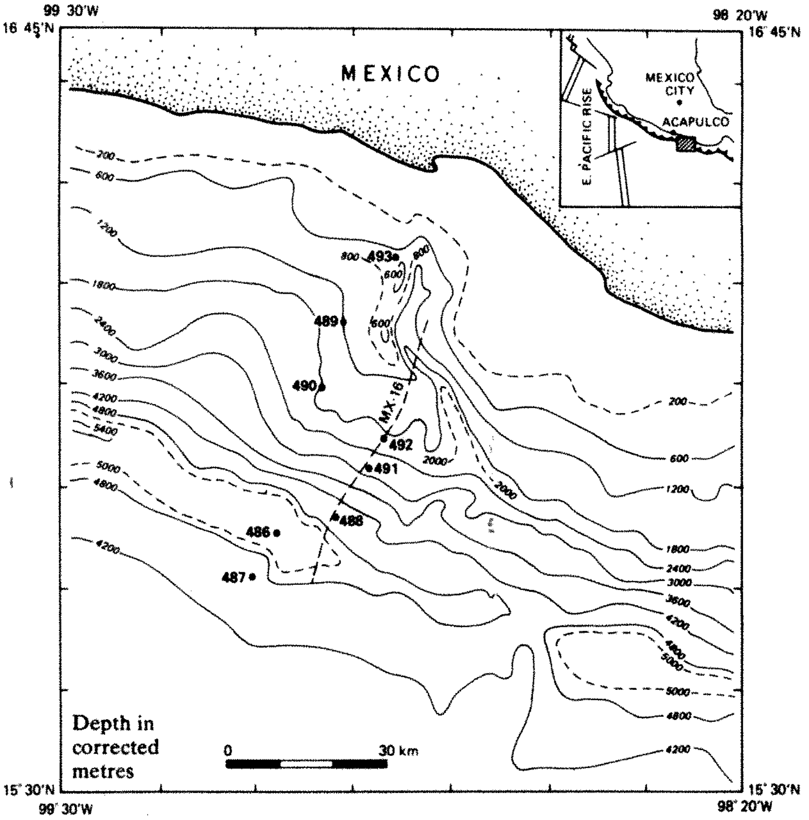

Fig. 1 Location of Leg 66 drilling sites. Dashed line covers the extent of the seismic profile MX16 shown in Fig. 3. Note the prominent submarine canyon which provides a conduit for transporting coarse-grained detritus directly into the trench and bypassing the slope on which Sites 488, 491 and 492 were drilled.

Sites 486 and 487 were located in the trench and on its outer slope respectively. These sites penetrated trench deposits and sediments overlying oceanic crust thereby sampling the type of material entering the subduction zone and providing a basis for interpreting deposits cored from the trench slope. At site 487 seaward of the trench, we penetrated 115 m of Pleistocene and latest Pliocene hemipelagic mud overlying 55 m of Pliocene to late Miocene brown clay, bottoming in basalt. At Site 486 two holes were drilled on the trench floor separated by ~1 km. In each case the abundance of sand caused the hole to collapse. The thickest section cored at Site 486 consisted of 38 m of fine to very coarse sand with mud. Piston cores taken by the University of Texas Marine Sciences Institute (UTMSI) elsewhere in the trench recovered abundant sand[15] suggesting that this is the dominant lithology in at least the uppermost deposits of the modern trench. Conversely UTMSI cores from the slope apron and lower slope basins in the Leg 66 area contain mud with rare fine thin sand and silt beds[15]. The high content of quartz and feldspar in the sand from the trench suggests it was derived from the crystalline basement of the adjacent continental margin probably via a prominent submarine canyon[16] (Fig. 1). Although the sand in the cores at Site 486 is massive, diagnostic sedimentary structures in some of the UTMSI piston cores from the trench indicates deposition by turbidity currents. Apparently the coarse sand cored at Site 486 moved across the narrow continental shelf and down the submarine canyon to the trench as a density underflow and effectively bypassed the slope.

Sites 488, 491, and 492 penetrated the lower to mid-slope region along UTMSI seismic line MX-16 (Fig. 1) and provided critical evidence for evaluating trench-slope evolution. Site 488, located at the toe of the trench slope at a water depth of 4,254 m, penetrated 313 m of Quaternary mud which below 170 m sub-bottom contains local thin silt and muddy sand beds (Fig. 2). Underlying the mud we cored 115 m of Quarternary mudstone and sand to pebbly sand bottoming at 428 m below the sea floor.

The sand-bearing unit of Site 488 must have been deposited in a major turbidite channel or basin. This unit could have accumulated in a turbidite channel or basin on the slope, however, such a structure was not detected in an exhaustive site survey and would have to have been obliterated. In view of the similarity of sand-bearing unit to deposits cored in the trench, we prefer to interpret it as an uplifted trench sequence. The virtual absence of significant sand beds in the upper Quaternary slope and slope–basin sediments from the piston and drill cores in the Leg 66 area, and the probable topographic diversion of down-slope sand transport from the site (Fig. 1) both argue against deposition of abundant coarse sand on the slope. If the sand-bearing unit accumulated in a trench of comparable depth to the present trench, then these sediments have been uplifted at a rate of 400–500 m Myr^{-1}.

The uniform hemipelagic muds above 170 m at Site 488 probably were deposited near their present position on the lower slope. The thin silt and sand beds between 170 and 313 m require a nearby conduit intermittently supplying fine sand and silt. These thin silt and sand beds probably accumulated when the underlying sand and mudstone unit was slightly elevated above the trench floor but still receiving fine-grained turbidites from the upper portions of large density underflows in the trench axis.

Site 491 lies at a water depth of 2,883 m, ~2 km above and 14 km landward of the Middle America Trench (Figs 1 and 3). Here, we cored 58 m of mud, overlying 380 m of mud containing local thin, fine sand layers, on top of 104 m of sand and pebbly sand interbedded with mudstone of early Pliocene age (Fig. 2). Below 39 m sub-bottom (~2 Myr BP) the sediments are barren of planktonic foraminifera and the nannofossil assemblages are much less abundant suggesting the site passed through the calcite compensation depth (CCD) at this time. In the Leg 66 area surface samples from piston cores and the DSDP sites place the modern CCD at 3,000–3,500 m below sea level. The CCD at 2 Myr BP is placed at 2,750–3,250 m with the shallowing in depth inferred from the documented time-depth variations in the central Pacific Ocean[17]. The depth of the CCD at Site 492 for 4 Myr BP is estimated similarly. We interpret the depositional environments of Site 491 as at Site 488, in terms of the modern example; the sand, pebbly sand and mudstone probably represent trench deposits and the overlying fine-grained sands, silts and muds probably accumulated on the slope during uplift of the underlying sediments. Alternatively, but less likely, the sand, pebbly sand, and mudstone could have accumulated in a lower slope basin or turbidite channel. If the sand, pebbly sand and mudstone accumulated in the trench or on the lowermost slope at water depths of 4–5 km it was uplifted initially at a rate of about 400 m Myr^{-1}. The uplift rate apparently slowed to less than 100 m Myr^{-1} after 2 Myr BP when the site passed through the local CCD at a depth of about 3,000 m.

At Site 492 in a water depth of 1,942 m we penetrated 247 m of Quaternary to Upper Miocene mud and mudstone overlying 43 m of Upper Miocene mudstone with sand and granular sand. In sediments about 4 Myr old at 50 m subbottom an abrupt decrease in carbonate content down-hole suggests the site passed through the CCD which is estimated to have been between 2,500 and 3,000 m below sea level at this time. Below 120 m the sediments are barren of foraminifera and contain a *Teichichnus–Zoophycos–Chrondrites* trace fossil assemblage suggesting accumulation at depths of 4 km or greater[18]. The sand bearing unit was probably deposited in the trench, based on the lines of reasoning for similar sand sequences at Sites 488 and 491. The age and depth of origin of the trace fossil assemblages, and the time of passage of Site 492 through the CCD define an initial uplift rate of about 500 m Myr^{-1} decreasing to about 200 m Myr^{-1} after 4 Myr BP.

Sporadic occurrences of shallowly dipping beds usually constitute the initial downhole evidence of deformation at Leg 66 drilling sites. At greater depths a gradual transition to cores with repeated occurrences of dips >25° represents the threshold of what we define as significant deformation. In addition to tilted bedding, discrete inclined fractures were common and small scale folds and overturned beds occurred locally. At Site 488 sediments between 210 and 248 m are characterised by healed fractures that truncate bedding and produce zones of stratal discontinuity, evidenced by discontinuous silt lenses in a mud matrix. At Site 492 mudstone intervals below 250 m resemble scaley clay where they are cut by slickensided anastomosing fractures. Deformation begins at shallower depths below the modern sea floor but in older sediments successively landward through Sites 488, 491 and 492 (Fig. 2); the age of the threshold of significant deformation is 0.6, 3.0 and 5.8 Myr at Sites 488, 491 and 492 respectively. Slope sediments are involved in the deformation in all cases; at Site 492 sediments that accumulated at depths as shallow as 3–4 km are deformed significantly.

Seismic reflection data

An extensive grid of multichannel seismic reflection profiles in the Leg 66 area facilitated site selection and aided interpretation[13]. Figure 3 is a migrated depth-section through Sites 488, 491 and 492, and shows the oceanic basement reflector extending about 15 km beneath the trench slope. Reflections defining the trench fill seem to be acoustically transitional to the zone of landward dipping reflectors underlying the trench slope.

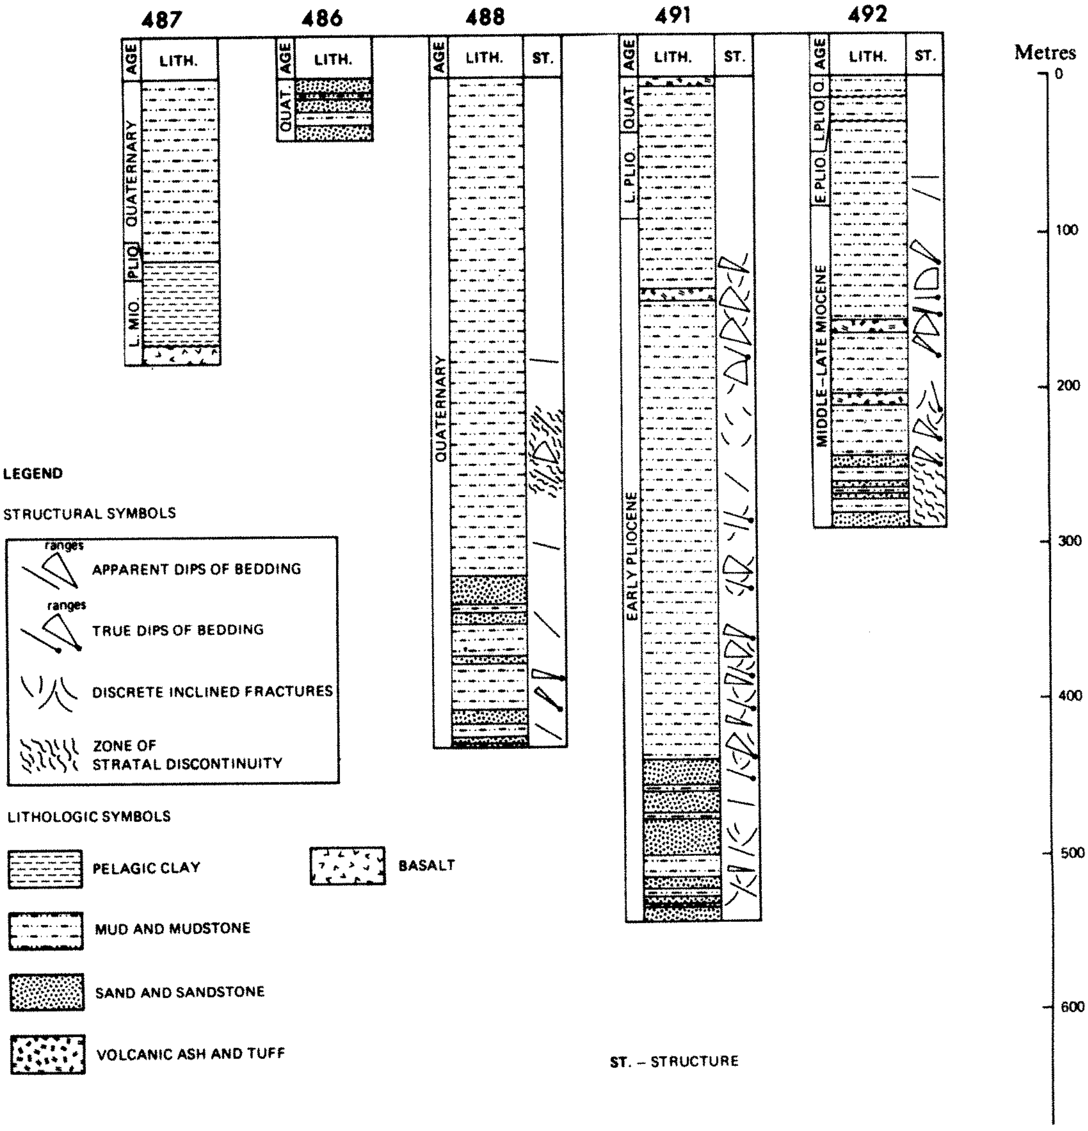

Fig. 2 Summary of lithology and structural geology for Sites 486–488, 491 and 492. The sand-bearing units, encountered at 313, 438, and 247 m at sites 488, 491 and 492 respectively, correlate with the zone of landward dipping reflectors whereas the overlying mud-rich units correlate with the slope apron (Fig. 3). The depth of significant deformation (repeated occurrences of dips greater than 25° occurs at 220, 116, and 80 m at Sites 488, 491 and 492 respectively.

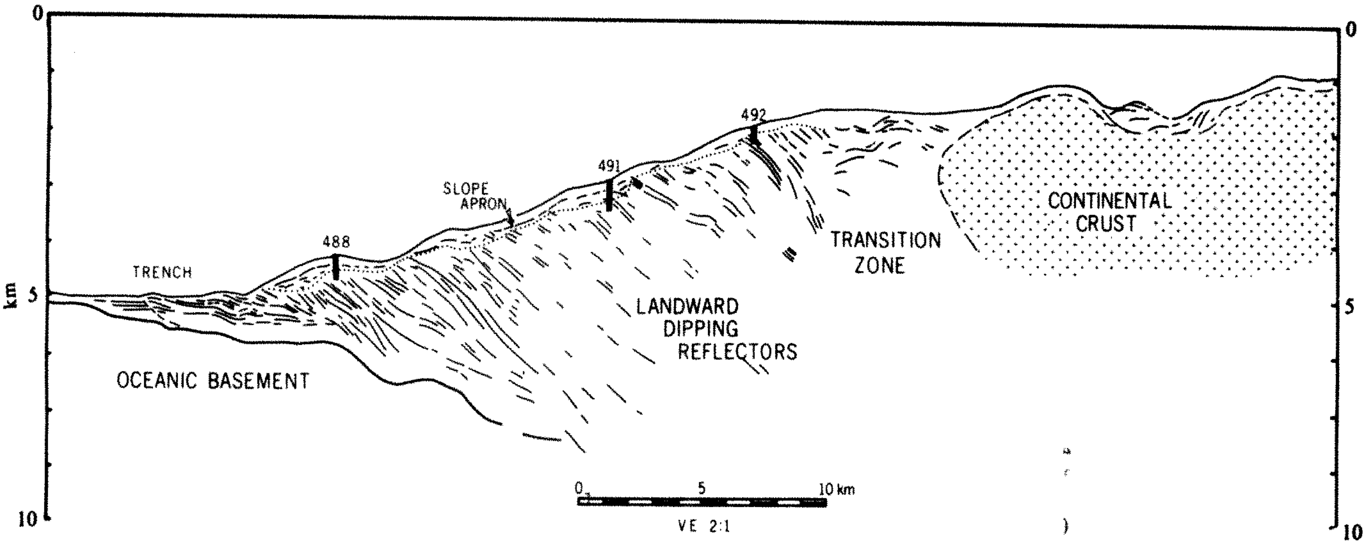

Fig. 3 Line drawing of the depth section MX16. Dotted line separates the slope apron from the landward dipping reflectors. The gas hydrate reflector is omitted for clarity.

Progressive landward inclination of dipping reflectors begins in the lowermost slope area; upslope their inclination remains relatively uniform. The zone of dipping reflectors is overlain by a mantle of discontinuous and indistinct reflectors, the slope apron, with a maximum thickness of 500 m. This slope apron consists of reflectors parallel to both the slope and to the underlying landward dipping reflectors.

The mud-rich sediments comprising the upper portion of the section at Sites 488, 491 and 492, the inferred slope deposits, correlate with the mantle of discontinuous and indistinct reflectors. The zone of landward dipping reflectors correlates with interbedded sand and mudstone units which begin at depths of 313, 438 and 247 m respectively at Sites 488, 491 and 492. Thus many of the landward dipping reflectors here are probably generated not by faults but changes in physical properties across bedding surfaces between the sand and mudstone units. The acoustic similarity of the trench fill and the landward dipping reflectors[13] also suggests that the latter represent bedding surfaces and that the interpretation of the interbedded sands and mudstones as trench deposits is correct.

Conclusions and discussion

The landward increase in age of the zone of landward dipping reflectors constitutes one of the most fundamental results of drilling on Leg 66 (Fig. 4). Such a systematic age progression indicates seaward growth of the continental margin irrespective of how the dipping reflectors are interpreted. We believe that these landward dipping reflectors are bedded units generated by thick sand and mudstone sequences which probably accumulated in the trench, or less likely on the lower slope. Thus, the landward increase in age in these dipping reflectors represents a stratigraphic inversion most simply explained by underthrusting along surfaces sub-parallel to bedding.

Shipboard palaeontological results did not resolve stratigraphic inversions in a single drillhole, even though one site (Site 488) was located to penetrate a seismically inferred thrust fault. Nevertheless, zones of stratal discontinuity and scaley clay, and anomalies in physical properties, suggest faulting and/or shear zones cutting the section cored at Sites 488 and 492. The gross stratigraphic inversion between sites suggests that thrusting occurs within discrete zones between our drilling locations and/or as distributed shear on numerous faults of small displacement. The pervasively sheared and disrupted fabrics common to inferred ancient and subduction complexes support the latter interpretation.

Although our palaeobathymetric data are preliminary, they consistently indicate uplift of the trench slope at Sites 488, 491 and 492. Quaternary rates are most confidently established suggesting uplift of 400–500 m Myr^{-1} at Site 488, decreasing to 200 m Myr^{-1} or less at Sites 491 and 492. Significantly, palaeobathymetric data suggest that the inferred trench and/or lowermost slope deposits of Sites 491 and 492 underwent rapid uplift which subsequently decreased to the slower rates characteristic of the Quaternary. Thus both the present distribution of Quaternary uplift rates and the historical records of Sites 491 and 492 argue for a high rate of uplift on the lowermost slope with a diminishing rate of uplift landwards.

The deformation in cores from Sites 488, 491 and 492 includes overturned folds, small-scale disruption of layering and scaley clay all of which occur commonly in subaerially exposed subduction complexes. In the Leg 66 cores the trench and the immediately overlying lowermost slope sediments are similarly deformed though the intensity of deformation decreases upsection through sediments accumulated at shallower depths. The tilting of sedimentary layering in cores accumulated at 3–4 km of water depth (50–120 m sub-bottom) at Site 492 indicates continuing deformation of the slope a substantial distance from the trench. Thus since the deformation is

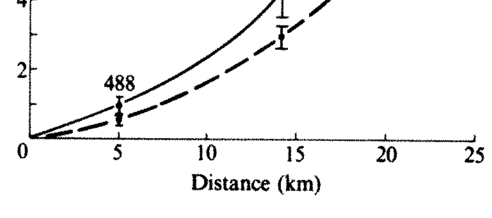

Fig. 4 Age of dipping reflectors (solid line) and youngest significant deformation (dashed line) versus distance from base of trench slope. Age of dipping reflectors taken from age of top of sand-bearing units (Fig. 2). Age at which youngest significant deformation occurs specified in caption, Fig. 2. Error bars indicate uncertainty in biostratigraphic age determinations.

apparently continuing upslope, away from the trench, the age of significant deformation at each site (Fig. 4) can be used as an indicator of the relative rates of deformation. The time required to develop significant deformation increases by a factor of 5 from 5 to 14 km from the base of the slope, and by an order of magnitude from 5 to 20 km from the base of the slope (Fig. 4). In other words, the rates of deformation at Sites 491 and 492 are respectively one-fifth and one-tenth of that observed at Site 488.

The folded beds and disrupted layering documented at Sites 488, 491 and 492 are probably due to both tectonic and gravity processes; the evidence concerning individual structural features is ambiguous. Nevertheless, correlation of the high rate of deformation at Site 488 with the high rate of uplift and rapid change in tilt of dipping reflectors indicates a concentration of tectonism near the base of the trench slope. Thus if gravitational processes are active in producing the structural features seen in the cores they too are accentuated at the base of the trench slope probably in response to the concentration of tectonic activity.

We thank the NSF and agencies in the FRG, France, Japan, UK and USSR for support of the Deep Sea Drilling Project; and the marine crew, drilling crew, and technical staff of the Glomar Challenger for assistance. We also thank R. Garrison, R. von Huene and D. Seely for helpful comments.

A volcanic ash generated by explosions where ignimbrite entered the sea

George P. L. Walker

Geology Department, University of Auckland, Private Bag, Auckland, New Zealand

A remarkably widely dispersed and crystal-rich volcanic ash-fall deposit is described, which resulted from immense explosions generated in the littoral zone in New Zealand where a major rhyolitic ignimbrite flowed into the sea. This partially explains what happens when large pyroclastic flows enter water.

THE rhyolitic volcanoes of the Taupo Zone have produced extensive air-fall ashes in addition to the ignimbrites for which they are better known. The tephrochronology of these ashes is well documented[1–4], but volcanological interpretations have seldom been attempted. The greatest air-fall deposit of the past ~50,000 yr is the Rotoehu ash, part of which is described and interpreted here.

The Rotoehu ash is remarkable for its large volume, previously estimated[5] to be at least 50 km^3 but now believed to be much more. It is also widely dispersed over most of the North Island of New Zealand, and is extremely rich in crystals which show up in its coarser beds. An isopach map is given by Vucetich and Pullar[5]. It is a distinctively shower-bedded fall deposit, and here we consider the thickest and uppermost and most widely dispersed of the three coarsest beds (bed G in Fig. 2).

The Rotoehu ash is intimately associated with the non-welded Rotoiti ignimbrite, the latest major ignimbrite from the Okataina volcano, and Nairn[6] has demonstrated that parts of the ash underlie, overlie, and are interbedded with flow units of the ignimbrite. The ignimbrite covers about 830 km^2, Fig. 1, and is known by its stratigraphic name as the Rotoiti Breccia. It is believed to have originated from a vent or vents in the Haroharo complex of Okataina volcano, and reached the coast of the Bay of Plenty 30 km from source along a front of more than 10 km. The ^{14}C age is about 42,000 years[7,8]. The estimated volume is 50 km^3.

Characteristics of the deposit

Bed G has a loose and sandy texture, and within 50 km of the Rotoiti ignimbrite outcrop it contains scattered fragments of ragged pumice up to several centimetres in size. It is conspicuously rich in crystals, resembling a waterlain sand. The relative uniformity in grain-size and thickness over a great area, the perfect mantle bedding, and the lack of rounding of the grains,

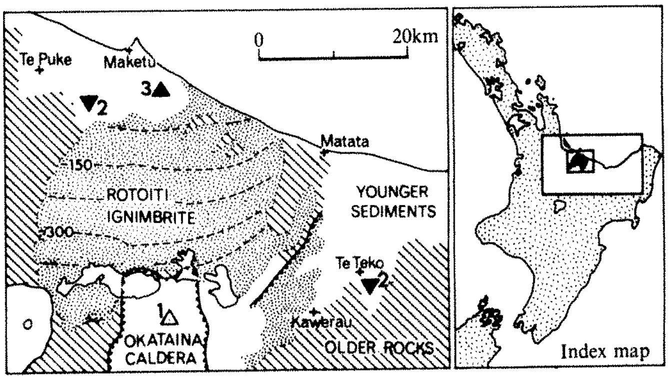

Fig. 1 Map showing the main outcrop of the Rotoiti ignimbrite, and the approximate locations of its source vent (1), the two littoral vents of Rotoehu ash bed G (2), and the littoral vent of ash bed E (3). The ignimbrite forms a northward-sloping aggradational surface (dashed lines indicate generalised contours, heights in metres); anomalously high south of Matata which is attributed to post-Rotoiti uplift of the land bordering the young rift vally in which Te Teko is situated. An older non-welded ignimbrite separated from the Rotoiti by a soil also occurs but is not distinguished on the map. The extent of the Rotoiti ignimbrite under the sediment flats of Te Puke and Te Teko is not known. The index map of the North Island of New Zealand shows the location of the studied area.

0028-0836/79/430642—05$01.00

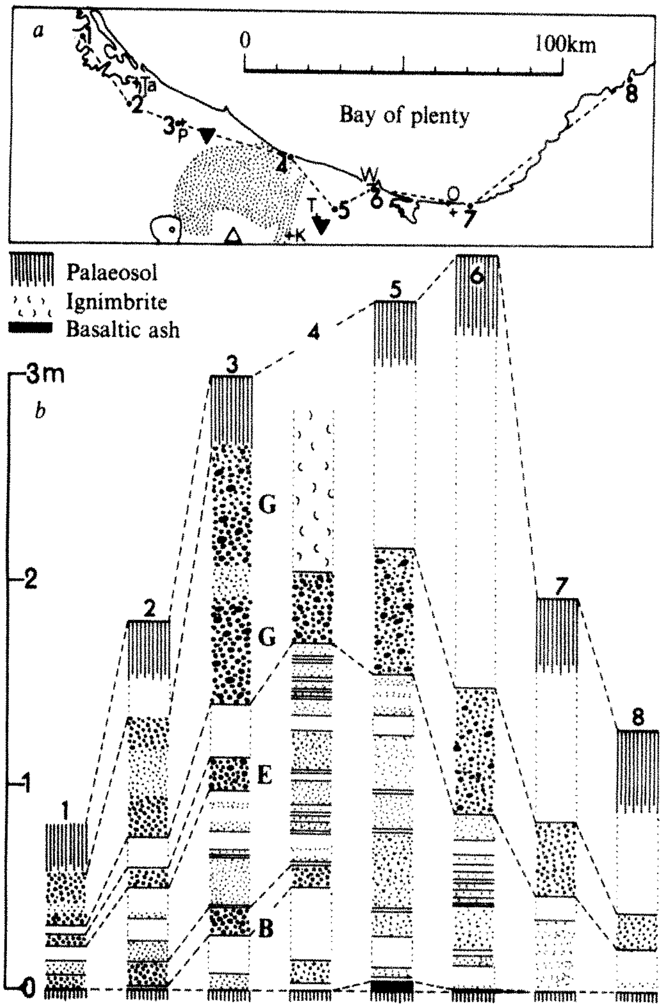

Fig. 2 *b*, Profiles of the Rotoehu ash at locations shown on the sketch map (*a*), in which the grain size of the beds is shown by the coarseness of the stipple (the finest ash is unstippled), showing the relative positions and thickness variations in the three main sandy beds, B, E and G. Place names K, Kawerau; O, Opotiki; P, Te Puke; Ta, Tauranga; T, Te Teko; W, Whakatane.

however, leave no doubt as to its shower origin. In the east and south, G is the coarsest and most prominent sandy bed in the Rotoehu ash. It is underlain by well bedded fine and sandy ashes, and is overlain by fine loess-like ash. In the west, G is the thickest, though not always the coarsest, of the sandy beds; it has a rather finer middle part and grades upwards to finer ash, and the weathered zone often extends well down into it, destroying its loose sandy texture.

The maps of bed G, Fig. 3, reveal the wide dispersal; the thickness and maximum grain-sizes decrease to half their value over a distance of 20–50 km, which is a remarkably low decrease rate for a fall deposit.

Sieve analyses have been made of 54 samples of G, using a set of sieves in which the aperture size of each is half that of the sieve above, and for each sample the percentages of components (pumice, free crystals, and lithics) have been determined for each size class down to 0.25 mm. For convenience, the size class is denoted by the aperture size of the sieve that retains it. 'Pumice' includes vesiculated juvenile fragments whatever their size, and also the bubble-wall shards which are abundant in fractions finer than 0.25 mm.

Lateral variations in grain-size characteristics are shown in Fig. 4*a*, and in crystal content by Figs 4*b* and 5. Figure 4*c* shows that the percentage of crystals decreases outwards in each size class due to aeolian fractionation: crystals have fallen closer to source than pumice of the same size. The decrease rate is remarkably low: crystals constitute more than 50% of the 0.5 mm class out to as far as 80 km from the ignimbrite outcrop.

South of Rotorua, G is missing and ash rich in accretionary lapilli occurs instead. Fine ash was thought to be flushed by rain from the eruptive cloud together with coarser material near Rotorua so that bed G is not recognisable as such, and by the time the cloud spread farther south it had largely been cleansed of ash.

Origin

The thickness and maximum grain-size decrease rate resembles that of a plinian pumice, but bed G differs from such a deposit in three ways. First, it totally lacks ballistic clasts; the largest pumice and lithic fragments noted measure 8.4 and 4.6 cm in maximum size respectively. Second, the median diameter is never coarser than 1 mm. Third, the overall grain-size distribution clearly has a strong mode in the 0.5 and 0.25 mm classes which predominate in all samples out to 100 km from the ignimbrite, Fig. 4*a*, and this mode consists mainly of crystals.

Bed G is interpreted as originating from vast explosions at two places where pumice flows of the Rotoiti ignimbrite entered the sea, based on two independent lines of evidence: the field data, and the peculiar grain-size characteristics of the bed.

First, the thickness and maximum grain-sizes reach a maximum at two places about 45 km apart, one near Te Puke and the other near Te Teko, Fig. 3 *a,c,d*, and likewise the content of coarse material from sieve analyses, Fig. 3*e*. These sites are on alluvium and are believed to mark the rootless vents of the littoral explosions by which bed G was generated. Sea bays are postulated to have projected to them at the time of the eruption. The thickness and grain-size decrease rate out from the Te Teko vent is lower than from the Te Puke vent suggesting that the Te Teko explosion was the more powerful, and the lack of stratification in bed G in the eastern area indicates a single short explosion of uniform intensity.

Second, G originated from a pyroclastic mixture that was more like that of a pyroclastic flow than that ejected at a primary explosion vent. Consider the special grain-size features of ignimbrite and their origin. Ignimbrite is constituted from the pyroclastic mixture which leaves the primary vent. The crystals are phenocrysts liberated from the magma, and the phenocryst content of large pumice clasts taken from the ignimbrite is believed to equal that in the original magma and for the Rotoiti ignimbrite and bed G is 24 wt %.

Three processes then modify the pyroclastic mixture so that the resulting ignimbrite departs considerably from the initial population. One is a loss of fine vitric particles, from the eruptive column and the moving flow, which eventually settle as a co-ignimbrite ash-fall largely beyond the limits of the ignimbrite. The loss generally amounts to about half of the total erupted mass, as is indicated by the two-fold concentration of free crystals in the ignimbrite[9,10]. The second process is the settling out of heavy clasts from the pyroclastic flow, the largest as a near-vent lag-fall deposit[11], and smaller ones as a lithic concentration zone near the base[12], or as a ground layer beneath, the ignimbrite[13]. This results in an outward decrease in maximum lithic size and content[14]. The third process is a progressive fragmentation of pumice within the flow.

All three processes seem to have operated in the Rotoiti ignimbrite. In distal exposures the ignimbrite has a low content of lithics and a maximum lithic size of ~5 cm; the content of free crystals is high, with a strong mode in the 0.5 and 0.25 mm classes; and the pumice distribution is strongly fine-skewed.

The characteristics of the distal Rotoiti ignimbrite are summarised by Fig. 6*a*. A big contrast exists between samples taken from near the base or from the middle/upper part, the former being much richer in lithics and the latter in coarse pumice (Fig. 5), and Fig. 6*a* is averaged from three samples taken from each position. The ignimbrite consists of many flow units, and the one which gave rise to bed G has not been identified.

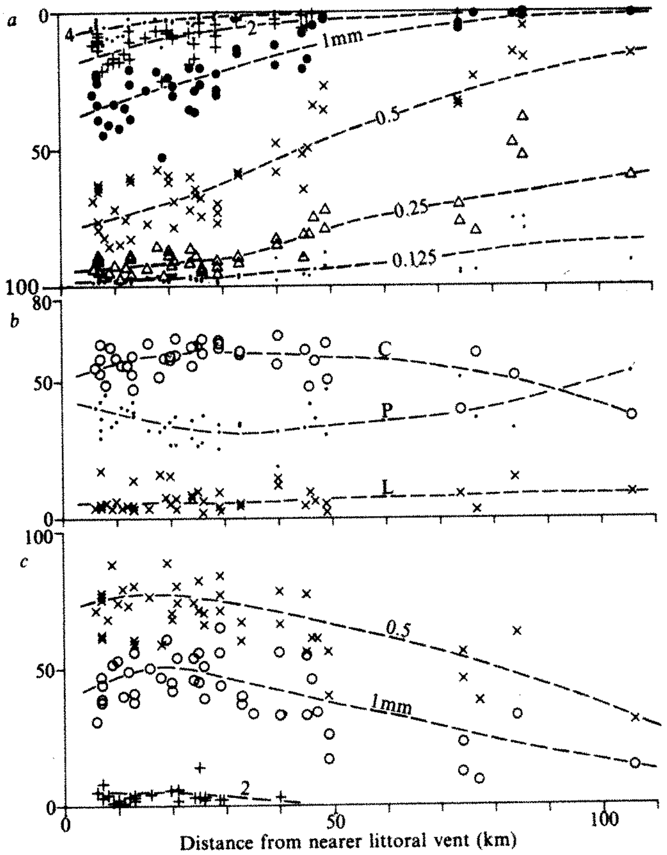

Fig. 4 Characteristics of the Rotoehu ash bed G as they vary with distance from the nearer littoral vent: *a* Cumulative wt% coarser than the size stated, for all sieved samples. Note the broadness of the band between 1 and 0.25 mm; the 0.5 and 0.25 mm size classes predominate in all samples irrespective of their distance from the vent. *b*, wt% of pumice (P), crystals (C) and lithics (L) in the sum of the 0.25 and coarser classes, recalculated to 100% total. Note that crystals predominate in almost all samples; *c*, The wt% of crystals in three grain-size classes, expressed as a percentage of that class.

The overall grain-size constitution of G has been partially determined as for the Taupo plinian pumice[15], by drawing maps of the mass per cm^2 of each size class and then integrating to yield the total mass of the class. These integrated values are plotted in Fig. 6*b* and compare closely with the average Rotoiti ignimbrite. The origin of bed G from Rotoiti ignimbrite material can be deduced from the size data and constitution since these are predetermined by the pyroclastic mixture available, characterised by a small maximum clast size, a high content of crystals, and a small content of pumice coarser than 1 mm.

Phreatomagmatic pyroclastic deposits formed where water enters the primary vent have a similar strongly fine-skewed population[16], but ballistic fragments are also invariably present. Furthermore, such eruptions are pulsatory, so that fine material from weaker activity falls together with coarse from stronger activity, to produce poorly sorted deposits even very close to vent; in contrast, bed G is well sorted everywhere.

The volume of bed G within the 25 cm isopach is 6 km^3, assuming bilateral symmetry about the Te Puke–Te Teko line, but much lies outside this isopach. When a plot of the area enclosed by isopachs is extrapolated out to 1 cm, the volume by integration is 20 km^3, but the extrapolation is uncertain. The formula of Cole and Stephenson[17,18] (taking the two vents separately) yields a total of 14 km^3.

Another way of estimating the volume is by assuming that G originated from the average Rotoiti ignimbrite of Fig. 6*a*. Based on the quantity of material 0.5 mm or coarser (Fig. 6*b*), the total mass of G is 12×10^{15} g (equals 11 km^3 at a density of 1.07 g cm^{-3}); based on the content of crystals 0.5 mm or coarser, the mass is 18.6×10^{15} g (= 17 km^3); and based on the quantity of crystals in the 0.5 mm class the mass is 20.5×10^{15} g(= 19 km^3).

Discussion

The exceptionally wide dispersal of bed G, and the efficient aeolian fractionation of crystals even 100 km from source, indicate that the secondary eruptive columns above the littoral explosions must have been exceedingly powerful. The area enclosed by selected maximum pumice and maximum lithic size isopleths (Table 1) is comparable with that given by the most powerful known plinian eruption, that of Taupo AD 131 (ref. 15). It is very much greater than for other known deposits of rootless vents (for example, in Iceland[19] and Hawaii[20]).

The extreme violence of the Rotoehu event must result from an exceedingly high energy release rate. The best mechanism seems to be one in which about 15 km^3 of hot pyroclastic flow entered the sea very rapidly at Te Puke and Te Teko and spread over perhaps tens of square kilometres before coming to rest. The first part to enter the sea became well mixed with water, and the rapid exposure of a great surface area of the hot particulate material resulted in a very rapid heat exchange with the water. This part, however, was rapidly over-ridden and buried beneath newly-arrived material, delaying the explosive expansion of the resulting steam. When the supply of material fell, the pressure build-up exceeded the rate of addition of material, and explosive disruption of the entire mass then occurred.

The abnormally high crystal content of bed G stems from an initial high magmatic content, combined with the subsequent successive operation of two crystal concentration processes: the selective loss of vitric dust above the primary vent and moving flow, and the aeolian fractionation of material falling from the littoral explosions. The exceptional violence of the explosion resulted in a high crystal content persisting even to 100 km from source.

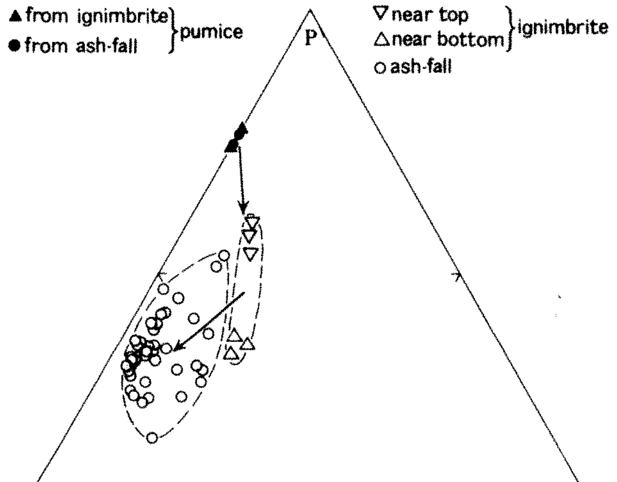

Fig. 5 Triangular plot showing the weight percentages of pumice (P), crystals (C) and lithics (L) in samples of the Rotoehu G ash and Rotoiti ignimbrite, for the sum of the 0.25 mm and coarser classes recalculated to 100% total. Crystal contents of pumice clasts from the ash and ignimbrite were determined by crushing followed by mechanical separation, and are thought to be representative of the original magma. The arrows show the two stages of crystal enrichment beginning with the original porphyritic magma.

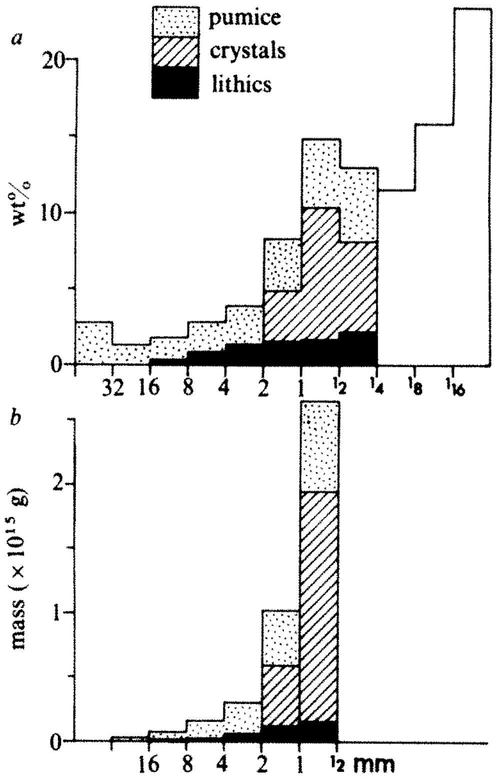

Fig. 6 *a*, Histogram of the average grain-size distribution in six sieved samples of the Rotoiti ignimbrite; the bars are subdivided on their weight percentages of components. *b*, Histogram of the total mass of grain-size classes and their components in the mapped part of the Rotoehu ash bed G; the vertical scale has been adjusted so that the total length of bars for the 0.5 mm and coarser classes in (*a*) and (*b*) is the same.

The other two main sandy layers (B and E) in the Rotoehu ash have similar characteristics and formed by similar explosions of earlier Rotoiti ignimbrite flow units. Bed E was evidently formed where a flow entered the sea south-east of Maketu (3, Fig. 1). Its volume and dispersal are comparable with the eastern part of G from the Te Teko rootless vent. The fine ashes within the Rotoehu ash may be normal co-ignimbrite ash-falls or may represent weaker littoral activity.

The Te Teko explosion which gave rise to half of bed G and that which gave rise to bed E seem to have been the most violent volcanic explosions yet documented by ash dispersal studies. This is reminiscent of the 1883 eruption of Krakatau, which was accompanied by major explosions and culminated in three immense paroxysms during which tsunamis were generated. It has long been supposed that seawater was a major factor in producing such extreme violence, but there has always been uncertainty regarding the mechanism: whether it was by the sea entering the magma chamber or not.

Another possibility is that the Krakatau explosions were indeed caused by the interaction of magma and the sea, but the explosions were littoral ones where pyroclastic flows entered the water as at Te Puke and Te Teko. The classic studies of the pyroclastic products of Krakatau by Verbeek[21] and Stehn[22] indicate that puroclastic flow deposits on land were formed at the time of the biggest explosions. Testing of this idea, must, however, await a critical re-examination of the pyroclastic products of this event.

The picture which emerges is that ash bed G was deposited from an immense mushroom cloud which was tens of kilometres high and rapidly expanded until it was well over 200 km in diameter. This mushroom spread laterally outwards nearly

† Extrapolated values.

uniformly in all directions. The material which fell 100 km out from source has a median terminal fall velocity of 3 m s^{-1}, for which the fall time from a height of 10–50 km in normal atmosphere is 35–70 minutes. This suggests that the outward radial velocity of the expanding cloud averaged 180–90 km h^{-1} neglecting the dustiness of the atmosphere at the time and turbulence. The lateral expansion was apparently much greater than is normal in volcanic explosions, and was comparable with the most powerful one currently known. In normal explosions, the expansion is due to magmatic gases which constitute a few wt% of the magma. In the Rotoehu case it is possible that steam constituted a few tens of wt% of magma involved.

This ash is an example of a new class of pyroclastic deposit for which the name 'littoral co-ignimbrite ash-fall' is proposed.

I thank the Royal Society of New Zealand for supporting this research, which was done at the University of Auckland while I was on leave from Imperial College London, and my wife for assistance.

Nucleotide sequence of the hepatitis B virus genome (subtype ayw) cloned in *E. coli*

The complete nucleotide sequence of hepatitis B virus genome (subtype ayw) cloned in Escherichia coli *has been determined using the Maxam and Gilbert method and the dideoxynucleotide method. This sequence is 3,182 nucleotides long. Location of the nonsense codons shows that the coding capacity of the L chain is larger than the coding capacity of the S chain. Eight open regions, able to code for polypeptide chains larger than 100 amino acids, have been located. Region 6, which is the largest, covers more than 80% of the genome. The gene* S *which codes for polypeptide I of the Hbs Ag and was previously located between coordinates* 95.1 *and* 73.6 *is contained in region* 7.

HEPATITIS B VIRUS (HBV) infects man at a very high rate. In western Europe and USA, about 10% of the population carry an HBV serological marker such as the surface antigen (HBs Ag) or the corresponding antibody (HBs Ac)[1]. In some areas of tropical Africa and southeastern Asia, this percentage can be as high as 60% or 70% (ref. 2). Recovery is spontaneous in most cases, but the virus can cause very severe complications like fulminant hepatitis, chronic hepatitis and cirrhosis in addition to which a hepatocarcinoma can develop[3]. It has been estimated that there are at least 120 million chronic carriers of HBs Ag, the so-called healthy carriers, throughout the world[2].

In addition to HBs Ag, two other antigens have been identified: HBc Ag which corresponds to the core of the virus, and HBe Ag whose location within the virion has been recently demonstrated[4]. It was also shown that the viral genome is made up of a circular DNA molecule which is partially single-stranded and about 3,200 bases long[5,6]. The virion also harbours a DNA polymerase able to repair the viral DNA[7]. The novel structure of this virus makes its classification somewhat difficult.

The biological study of the virus is complicated by the fact that HBV cannot be propagated in cell cultures and the only available viral source remains human serum. However, cloning of the HBV genome in *Escherichia coli* has allowed the purification of large amounts of genetically homogeneous HBV DNA, and the establishment of several restriction maps[8–10]. Hence we have recently[11] localised and determined the primary structure of the *S* gene which codes for polypeptide I and its glucosylated derivative polypeptide II, which are the major components of the HBs Ag.

In this article, we report the complete primary structure of the viral genome (subtype ayw) previously cloned in *E. coli.*

Primary structure of the cloned viral genome

Fig. 1 Viral DNA (serotype ayw), repaired with the endogenous DNA polymerase and the four nucleotide triphosphates, was digested with *Eco*RI endonuclease and cloned in *E. coli* using λ gt WES bacteriophage as the cloning vehicle[16]. The cloned DNA was referred to as *Eco* HBV DNA. To avoid genetic drift, all stocks used to analyse the DNA sequence were made on plates from the same lysate obtained after the first cloning step. Recombinant phages were purified by two successive CsCl gradients and the DNA was phenol extracted[11]. After hydrolysis with *Eco*RI endonuclease, *Eco* HBV DNA was separated from the two λ arms by sucrose gradient ultracentrifugation[17]. To prepare each set of restriction DNA fragments, 25 to 30 μg of *Eco* HBV DNA were fully hydrolysed with one of the restriction enzymes described in Fig. 2, using the conditions recommended by the manufacturer (Biolabs). Restriction fragments were dephosphorylated by incubation at 65 °C for 45 min with 4 μl of bacterial phosphatase. This enzyme was then inactivated by alkaline treatment[18] and DNA fragments were 5′ labelled with [γ-^{32}P]ATP (NEN; specific activity 2,500 Ci mmol^{-1}) and polynucleotide kinase (P. L. Biochemicals) as described by Maxam and Gilbert[12]. Labelled fragments were fractionated by gel electrophoresis and eluted from the gels as previously described. The two labelled ends of each restriction fragment were then separated either by hydrolysis of the DNA fragment with another restriction endonuclease and gel electrophoresis or by heat denaturation in the presence of 30% dimethyl sulphoxide and gel electrophoresis[13]. DNA fragments labelled at one 5′ end were eluted from the preparative gel and dissolved in water. Chemical reaction, specific for G, A + G, C + T, T and A + C giving a stronger band for A than C were performed as described previously[12,13,17]. Sequence reaction products dissolved in loading solution were heat denatured and fractionated on 25, 16 and 8% acrylamide gel. Figure 1*a* is an example of fractionation on an 8% acrylamide slab gel of the sequence reaction products obtained with *Hinf* C″ DNA fragment (nucleotides 658 to 552). When the two labelled ends were separated by hydrolysis with a restriction enzyme, nucleotide sequences were also determined with the dideoxynucleotide method[14] adapted by Maat and Smith[15] for double-stranded DNA fragments. Figure 1*b* is an example of fractionation on a 16% acrylamide gel of such reaction products obtained with *Bgl* A′ fragment (nucleotide sequence from residue 1,264 to residue 1,338). The two G lanes correspond to two different reaction conditions. In Gl there is no dGTP while in G2 the final concentration of dGTP is 2 μM. In both reactions, there is 1 mM ddGTP, final concentration. Subscript prime indicates the position of the ^{32}P on the L strand, subscript second, its position on the S strand.

double-stranded DNA by Maat and Smith[15] were used. Two examples of sequencing gel autoradiograms are shown in Fig. 1. To analyse independently both DNA strands and to overlap all the restriction sites used as starting points, a large number of fragments were analysed (Fig. 2). The localisation of the 5′ end of the largest DNA strand on the *Bam*HI viral restriction map and the knowledge of this restriction map on the *Eco* HBV DNA allowed the identification of the cloned DNA strands with respect to the viral DNA strands. Here we call the DNA strand of *Eco* HBV DNA homologous to the longest viral DNA strand the L strand, and the other, the S strand. The sequence shown in Fig. 3 corresponds to the *Eco* HBV DNA, which is 3,182 nucleotides long.

Location of the open reading frames on the viral genome

A computer program was used to search for nonsense codons on both DNA strands[19]. It appears from Fig. 4 that the number and distribution of nonsense codons are very different on S and L strands. Considering the total genome length, a random distribution of nucleotides should give about 50 nonsense codons in each reading frame. Instead one observes 33, 29 and 15 nonsense codons in the S strand for each phase and 61, 60 and 41 nonsense codons on the L strand. In addition, their distribution along the DNA molecule is very different on the two strands. On the L strand, the open reading frames are relatively short (Fig. 4). Four regions are able to code for 100 amino acids or more. These four regions labelled 1 to 4 are 510, 327, 447 and 345 nucleotides long. On the S strand (Fig. 4), the open regions are much longer. These regions labelled 5 to 8 are 498, 2,553, 1,296 and 657 nucleotides long. The length of the above hypothetical coding regions which include the *Eco*RI restriction site (such as regions 4, 6 and 7) is only valid if no DNA has been lost in the vicinity of this restriction site on cloning, which is most likely. In spite of this limitation, the distribution of stop codons clearly shows that the coding capacity of the L strand is larger than that of the S strand.

Regions 1, 2, 3 and 4 appear to be located on the genome as two pairs (Fig. 5)—region 3 is located immediately downstream of region 1 and region 2 immediately beyond region 4. Regions 5, 6, 7 and 8 extend over the whole genome and overlap with each other in different reading frames (Fig. 5). Region 6 covers about 80% of the genome and includes the whole of region 7 and part of regions 5 and 8. Regions 6 and 7 correspond partly to the single-stranded region of the genome. Regions 4 and 5 cover the 5′ extremity of the S strand and the nick of the L strand.

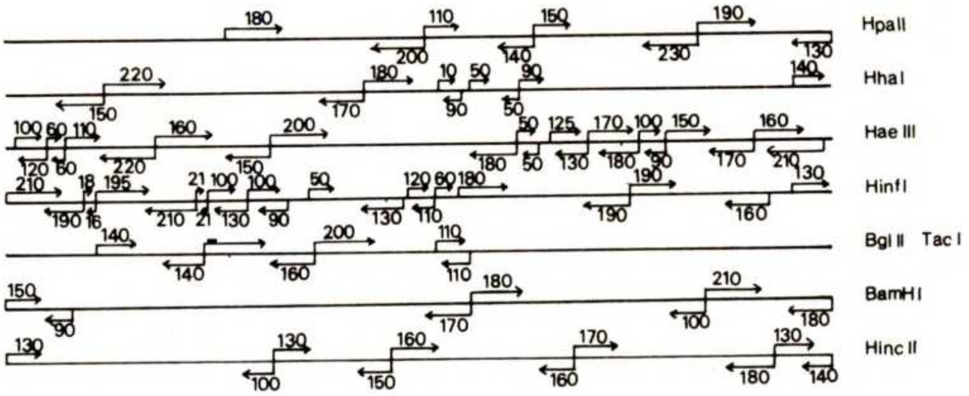

Fig. 2 Diagram of analysed DNA fragments. Vertical bars correspond to the position of the 5′ labelled ends of restriction fragments used to determine the nucleotide sequence of the *Eco* HBV DNA. Numbers above each arrow indicate the length of nucleotide sequences analysed from the restriction sites.

Tentative translation of open regions

Few proteins have been shown to be coded by the viral genome[9,11], but one can suppose that, because of its very small size, regions with open reading frames are largely used for translation. Therefore, a search for the ATG codons which could initiate translation has been made near the beginning of these regions, although the existence of mRNA splicing[20,21] could complicate the translation of the open regions. The positions of these ATGs are shown by small arrows in Fig. 5. In region 1 to 4, the numbers of codons located downstream from these ATG codons are 79, 60, 145 and 28 respectively. Regions 2 and 4 have particularly low coding capacities. However, these coding capacities could be modified by mRNA splicing. For example, the translation from the first ATG located in region 4, of mRNA transcribed from regions 4 and 2 and spliced could allow the synthesis of a polypeptide with a molecular weight (MW) up to 18,000. For simplicity and clarity, only regions with an open reading frame able to code for 100 amino acids or more are taken into account. But a more complicated splicing pattern of mRNA could link, in one open reading frame, areas with small coding capacity scattered all along the genome. If region 3 which spans in the single-stranded part of the genome is actually translated into protein, this can happen only after DNA synthesis of the missing strand.

In regions 5, 6, 7 and 8, the situation appears to be very different. The number of codons located downstream of the first ATG are respectively 154, 832, 389 and 212. Region 6 (2,553 nucleotides long) contains 9 ATG codons. The first and second are located at 57 and 1,296 nucleotides respectively from the beginning of this region. The seven other ATGs are regularly distributed in the second half of this region. In the case where translation is initiated at the first ATG, a protein of MW 90,000 might be synthesised. DNA polymerases and reverse transcriptases have a MW of that order[22,33], so it is tempting to suggest that the DNA polymerase found within the virion could be coded by this region.

By correlating the amino acid sequences of both ends of the HBs Ag polypeptide I[24] and the nucleotide sequence of the *Eco* HBV DNA, we are able to localise the gene coding for this polypeptide in region 7. This gene, called *S* gene, was previously located between positions, 95.1 and 73.6 on the genome map[11]. The ATG (position 3,030) corresponding to the N-terminal extremity of the polypeptide I is the third of region 7. It is located 618 nucleotides from the beginning of this region, whereas the two other ATGs (positions 337 and 13) are at 129 and 453 nucleotides from the beginning. The fact that the ATG 3030 is preceded by two other ATGs in the same open reading frame deserves some additional comment. Three explanations can be given: (1) Region 7 is completely translated and gives rise to a long polypeptide different from polypeptide I but whose C-terminal amino acid sequence is identical to polypeptide I. A similar situation occurs with protein VP2 and VP3 of SV40[25,26] and the 33,000 and 100,000 MW proteins of adenovirus 2[27]. (2) Region 7 is completely translated into a precursor protein of polypeptide I. (3) The region upstream of the third ATG is not translated. At the present time, one cannot choose between the

three hypotheses. Nevertheless, the first hypothesis could partially explain the presence of large polypeptides found in small amount in the HBs Ag preparations[24].

Translation of the terminal nucleotide sequence of region 8 would give rise to a polypeptide having at its C-terminal end a repeated sequence of 9 amino acids: Ser-Pro-Arg-Arg-Arg-Arg-Ser-Glu-Ser. The last amino acid of the first sequence, Ser, would be the first one of the second sequence. In the corresponding DNA sequence, however, the only repetition is TCTCAA (Ser-Glu). Beyond the ATG codon, region 8 contains 24 arginine codons—11% of the total codons. In the last 35 codons there are 16 arginine codons. This large proportion of basic amino acids is similar to that observed in histone, which suggests that the translational product of region 8 could be a polypeptide with a high affinity for HBV DNA. Therefore, if this region is translated, one could envisage that the HBc Ag could be coded by this DNA sequence.

Search for signal sequences

From a comparative analysis of the primary structure of viral or cellular mRNAs and of chromosomal DNA fragments, some remarkable DNA sequences were found. In several circumstances, a sequence identical or similar to 5'TATAAA was observed in front of the transcribed region (ref. 28 and D. Hogness and M. Goldberg, personal communication), while the sequence AAUAAA has been found at the 3' end of mRNA, near the poly(A)tail[29–31]. On the other hand, it has been shown that during the initiation of translation the 3'OH end of 16S ribosomal RNA hybridises to the 5' end of prokaryotic mRNA through the CCUCC sequence[32]. The occurrence of a similar phenomenon has not been demonstrated in eukaryotic cells. Nevertheless, sequences able to hybridise to the 3'GCGGAAGGA sequence of the 18S ribosomal RNA have been observed in some eukaryotic mRNAs[28,33–35]. Therefore, we looked for these sequences in the *Eco* HBV DNA. The 5'TATAAA sequence was found only at position 1,269 on the S strand at 335 nucleotides before region 6. It could therefore correspond to a signal relating to the initiation of transcription of this very large open region. In that case, since this sequence is followed by three ATGs (1,089, 1,022, 998) all in a closed reading frame, a splicing of the corresponding mRNA should

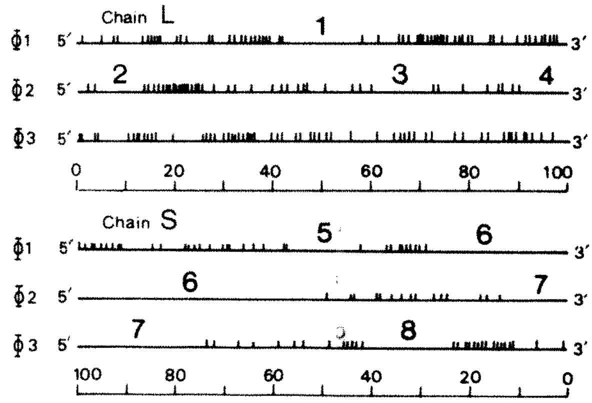

Fig. 4 Diagram showing the localisation of the nonsense codons on chains L and S of the *Eco*HBV DNA. Three reading frames, called Φ1, Φ2 and Φ3, were defined from the 5' end of each DNA strand. On the L chain, Φ1 is defined by its first triplet AAT, Φ2 by ATT and Φ3 by TTC. On the S chain, Φ1 is defined by its first triplet CCA, Φ2 by CAC and Φ3 by ACA. The viral DNA is circular and its length in nucleotides (3,182) is not a multiple of 3. Therefore, going through the *Eco*RI site phase Φ1 is change to phase Φ2, phase Φ2 to phase Φ3 and phase Φ3 to phase Φ1. Vertical bars represent stop codons. Numbers 1 to 8 define the areas with an open reading frame arbitrarily chosen with a length above 100 codons. Region 1 goes from nucleotide 1,351 to 1,860, region 2 from nucleotide 119 to 445, region 3 from 1,904 to 2,350, region 4 from 2,855 to 17, region 5 from 1,847 to 1,350, region 6 from 935 to 1 and from 3182 to 1565, region 7 from 466 to 1 and from 3,182 to 2353, region 8 from 1,392 to 736.

CALCUTTA

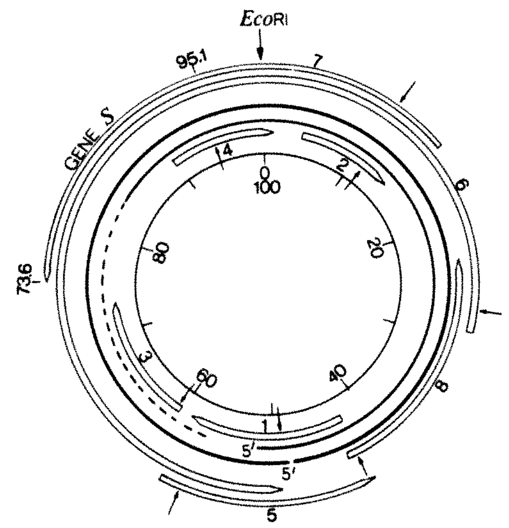

Fig. 5 Localisation of the open reading frames on the viral genome. The structure of the genome is shown as previously described[8]. The *Eco*RI site is the origin of the physical map. Block arrows define the open reading frames on the two viral DNA strands. The small arrows indicate the ATG codon located closest to the beginning of the open region. The *S* gene is located between positions 95.1 and 73.6 and is included in region 7.

take place to link its 5′ end to a nucleotide sequence corresponding to the open reading frame of region 6. Sequences which differ by only one nucleotide were found 36 times on the S strand and 45 times on the L strand. The 5′AATAAA sequence occurs once on the L strand at position 689, 243 nucleotides after the stop codon of region 2. This sequence is not found in chain S even at the end of gene *S* which is known to code for polypeptide I. Two sequences, 5′GCCTTCCT and CGCCTTCC, able to hybridise with the 3′ end of 18S RNA ribosomal, were found at positions 61 and 417 on the L strand. Sequences able to hybridise with 6 or 7 nucleotides of the 3′OH end of this RNA were found once on the L chain and 8 times on the S chain. Among these, the CCTTCC sequence located at position 3,176 on the S strand follows a short palindromic sequence 5′GTGGAATTCCAC 3′ starting at position 8. This feature could be related to the expression of the *S* gene located downstream.

Containment conditions for this study were recommended by the French National Control Committee. Growth of recombinant bacteriophages was done in L3B1 conditions. We thank Dr A. Fritsch for helpful discussion and reviewing the manuscript, Dr R. Studen for computer work, Dr A. Maxam for sending us the revised version of the Maxam and Gilbert sequencing method before publication, and Mrs Gobet for technical assistance. This work was supported by INSERM and CNRS.

Design, synthesis and characterisation of a 34-residue polypeptide that interacts with nucleic acids

B. Gutte, M. Däumigen & E. Wittschieber
Max-Planck-Institut für Biophysikalische Chemie, Abteilung Biochemische Kinetik, 34 Göttingen, FRG

Based on secondary structure prediction rules and model building a neutral artificial 34-residue polypeptide with potential nucleic acid-binding activity was synthesised. This peptide and its covalent dimer showed strong interaction with cytidine phosphates and single-stranded DNA. The dimer had considerable ribonuclease activity with high preference for cleavage at the 3′-end of C.

BASED on the known X-ray structures of proteins, rules were proposed by various authors (see ref. 1 for review) to describe the relationship between primary and secondary structure of a protein molecule. These rules may be applied to predict the secondary structure of proteins of which only the amino acid sequence is known. An example of this is the suggested succession of the secondary structural elements (α-helix, β-strand, reverse turn) in *Escherichia coli lac* repressor[2,3]. Proof or disproof of the proposed secondary structure will come from X-ray diffraction studies on crystalline *lac* repressor.

0028-0836/79/430650—06$01.00

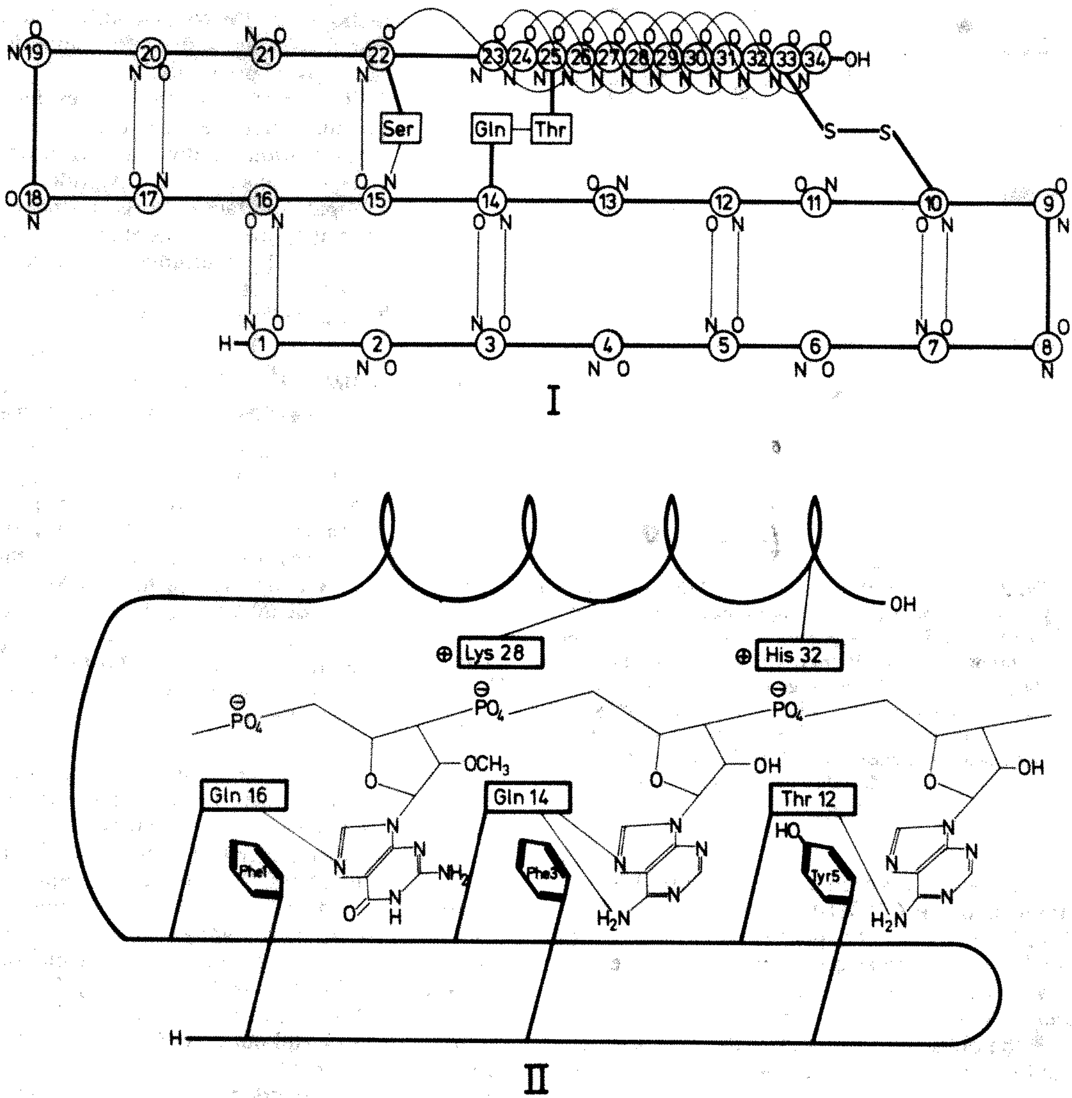

Fig. 1 Proposed secondary structure of synthetic 34-residue polypeptide (I) and possible interactions with the trinucleotide m$^{2'}$ GAA (II). I, Thin lines represent hydrogen bonds between the β-strands and within the α-helix, amino acid symbols in boxes are side chains involved in intramolecular hydrogen bonds. In the model, the helix axis lies slightly above the hydrophobic side of the β-sheet. The primary structure of the 34-residue polypeptide is given in the text. II, Heavy lines indicate the course of the peptide chain, thin lines show the trinucleotide. The side chains of the amino acid residues in boxes are proposed to be the main contributors to the interactions between the synthetic polypeptide and the trinucleotide. The ribose–phosphate backbone runs above the two parallels formed by the 10–17 strand and the helix axis. The bases point downwards onto the two-strand sheet formed by residues 1–7 and 10–17.

The secondary structure prediction rules may also be used to design functional polypeptides that do not occur naturally but that may be useful for scientific and industrial purposes. Although these rules will certainly become refined and more reliable as more X-ray structures of proteins become known, we decided to design a nucleic acid-binding polypeptide based on the present prediction methods. This system was chosen because of the great importance of nucleic acid–protein interactions in biology[4].

Rationale of the amino acid sequence chosen

The structure and the amino acid sequence of the polypeptide that could have the desired properties were determined in part by model building. The nucleotide sequence of the anticodon of yeast tRNA^{Phe}, m$^{2'}$ GAA (refs 5–7), was used as the ligand around which the backbone of a peptide chain was to be folded in such a way as to produce a shallow depression as binding site. This simple structure seemed to be formed best by a 34-residue polypeptide containing a β-strand, a reverse turn, an antiparallel β-strand, a second reverse turn, and an α-helix running antiparallel to the second β-strand as viewed from the NH_2-terminus to the COOH-terminus. Although this $\beta\beta\alpha$ arrangement was similar to the $\beta\alpha\beta$ units that make up the NAD$^+$-binding fold of the dehydrogenases[8,9], the proposed mode of interaction between the synthetic polypeptide and the trinucleotide was quite different.

The next step was choosing an amino acid sequence that, based on the prediction method of Chou and Fasman[10], had the potential to give the proposed folding and to form a sufficient number of specific noncovalent bonds with the ligand. Two additional prerequisites had to be fulfilled. First, the binding site was to be predominantly hydrophobic containing a few residues the side chains of which could act as hydrogen bond donors or acceptors; and second, binding was to be achieved mainly through specific hydrogen bonds and van der Waals contacts and only to a smaller extent through electrostatic interactions. The sequence chosen was as follows:

1 5 10
Phe-Thr-Phe-Thr-Tyr-Thr-Asp-Pro-Asn-Cys-Gln-Thr-Gly-
15 20 25
Gln-Gly-Gln-Asn-Pro-Asn-Gly-Ile-Ser-Glu-Pro-Thr-Ala-
30 34
Ala-Lys-Val-Ala-Gln-Ala-His-Cys-Ala

The proposed secondary structure of this peptide and its possible interactions with the ligand are shown in Fig. 1. Residues Phe 1 to Asp 7 were assumed to have an extended structure with the side chains of Phe 1, Phe 3, and Tyr 5 forming part of the binding site and allowing stacking interactions or intercalation with the bases of the trinucleotide ligand and the side chains of Thr 2, Thr 4, and Thr 6 pointing in the opposite direction, thus allowing interactions with the solvent. Residues 7–10 could form a β-turn and residues 10 to 17 could form the second strand of a β-sheet with the side chains of Thr 12, Gln 14, and Gln 16 hydrogen-bonded to the base moieties of the trinucleotide in a hydrophobic environment. Following the second

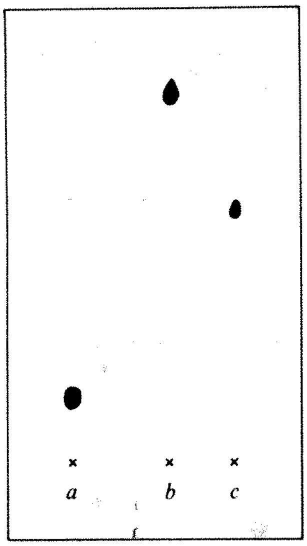

Fig. 2 Electrophoresis (*a*) and TLC (*b*, *c*) of purified synthetic 34-residue polypeptide. Electrophoresis was in 0.1 M pyridine-acetate, *p*H 5.8, on a precoated cellulose thin layer plate (20 × 20 cm) at 600 V for 50 min. The mobility of the spot was 2.3 cm. The product was also homogeneous on electrophoresis at *p*H 3.4. TLC was on precoated silica gel plates in ethyl acetate/acetic acid/pyridine/water (3:1:5:3) (*b*, R_F 0.80) and in *n*-butanol/acetic acid/pyridine/water (10:3:10:12) (*c*, R_F 0.50). Spots were detected by the Pauly spray.

β-turn, possibly produced by residues 17–20, a short third strand and the COOH-terminal α-helix comprising residues 23–34 completed the proposed secondary structure of the synthetic 34-residue polypeptide. The side chains of Ile 21, Ala 26, and Val 29 could be part of the hydrophobic binding site and the side chains of Lys 28 and His 32 could form salt bridges with the phosphate moieties of the ligand although the contribution of the latter interactions to the stability of the peptide–trinucleotide complex was probably weak, as in the model these salt bridges were on the surface of the complex. The disulphide bond between half-cystines 10 and 33 seemed to stabilise the proposed structure of the 34-residue polypeptide and its interactions with the trinucleotide. It also brought the side chains of three potential active site residues (Asp 7, Thr 12, and His 32) into spatial proximity.

The model of the 34-residue polypeptide–trinucleotide complex suggested the possibility of aggregation, either through continuation of the stacking interactions to the left of the NH_2-terminus of the peptide (Fig. 1, II) or through an antiparallel face-to-face arrangement of the NH_2-terminal heptapeptide portions of two 34-residue polypeptide molecules mediated by intermolecular hydrogen bonds between residues 2, 4 and 6 of one molecule (Fig. 1, I) and residues 6, 4 and 2, respectively, of the other.

Solid phase synthesis and purification of the 34-residue polypeptide

The 34-residue polypeptide was synthesised by the solid phase method[11,12] as described previously[13]. The amino acid composition of an acid hydrolysate of the protected peptide resin is given in Table 1. The 34-residue peptide was deprotected and cleaved from the resin by anhydrous HF in the presence of excess anisole at 0 °C and was extracted by 1 M acetic acid. After lyophilisation it was dissolved in 0.05 M NH_4HCO_3 adjusted to *p*H 8.8 with concentrated NH_4OH. The solution was stirred several hours and then desalted on a Bio-Gel P-2 column. The yield of crude 34-residue peptide was 67% based on the amount of COOH-terminal alanine esterified to the resin at the beginning of the synthesis.

The synthetic product was reduced with mercaptoethanol, reoxidised in dilute solution at *p*H 8.55 (ref. 13), and fractionated on a Sephadex G-50 column (78.5 × 2.7 cm) in 0.05 M NH_4HCO_3. The major fractions obtained were a polymer (yield, 5% of the amount applied to the column), a tetramer (yield, 19%), and the monomer (yield, 41%) which, after rechromatography, eluted between 136 and 154 ml, 211 and 247 ml (corresponding to the elution volume of lysozyme), and 272 and 308 ml, respectively. When 1 M HCOOH was used as eluant, the elution volume of the tetramer was increased to 240 to 270 ml but that of the monomer remained unchanged. This indicated that the tetramer was formed through association of two dimers the monomeric subunits of which were linked covalently by two intermolecular disulphide bonds. Whether the S–S bridges extended between Cys 10 and Cys 33 of one subunit and Cys 10 and Cys 33 or Cys 33 and Cys 10, respectively, of the

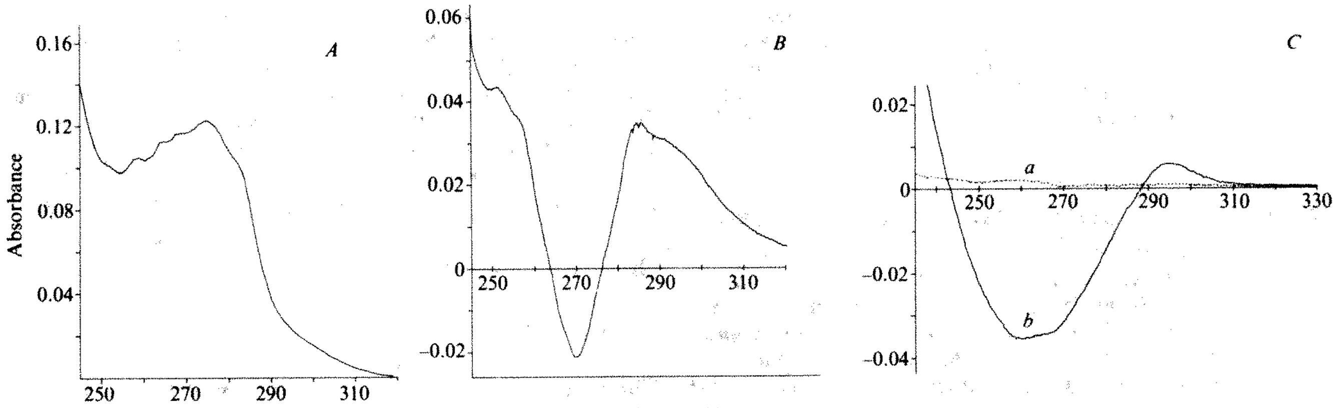

Fig. 3 *A*, *B*, UV difference spectrum of synthetic 68-residue polypeptide in the presence of cytidine 2′:3′-cyclic phosphate. Measurements were performed in a Cary 118 spectrophotometer. *A*, Spectrum of the 68-residue polypeptide (0.02 mM solution in 0.1 M sodium acetate, *p*H 5.3; *d*, 1 cm). *B*, Spectrum of the mixture after addition of the nucleotide to a concentration of 0.1 mM in both the control and the sample. *C*, UV difference spectrum of synthetic 34-residue polypeptide in the presence of single-stranded DNA. Single-stranded DNA was prepared from double-stranded calf thymus DNA by alkali denaturation. The 34-residue polypeptide was dissolved in buffer, *p*H 6.0, containing 0.06 M sodium chloride, 0.04 M sodium cacodylate, and 0.001 M EDTA. The separate compartments of two tandem cuvettes (*d*, 0.877 cm) were filled with 0.75 ml DNA solution (0.034 mg ml^{-1}) and 0.75 ml of peptide solution (0.24 mg ml^{-1}), respectively. After recording the base line (*a*), the contents of the two compartments of one of the cuvettes were mixed and the spectrum of the mixture was measured against that of the separate components (*b*). The UV difference spectrum produced by a mixture of the 68-residue material and single-stranded DNA was almost identical to that shown here.

other subunit or whether a mixture of both disulphide isomers was present, has not yet been determined.

Further purification of the 34-residue polypeptide and its dimer was achieved best by adsorption chromatography of 10-mg samples on a silica gel column (50×2.2 cm) in *n*-butanol/acetic acid/pyridine/water (20:6:20:24). The monomeric material that had the required amino acid composition (Table 1) was eluted between 102 and 109 ml in 35% yield based on the amount applied to the column. The major impurity eluting between 114 and 122 ml was a deletion peptide in which one threonine and one phenylalanine residue were missing. The purified monomer was homogeneous electrophoretically and chromatographically (Fig. 2). Fractionation of the dimer on silica gel gave similar results.

Interaction of the synthetic polypeptides with cytidine phosphates and single-stranded DNA

To visualise possible interactions between the purified synthetic 68- and 34-residue polypeptides and the $2':3'$-cyclic phosphates of adenosine, cytidine, guanosine, and uridine, UV spectra were recorded in a Cary 118 double-beam spectrophotometer. First, the 68-residue polypeptide was measured against the solvent, 0.1 M sodium acetate, *p*H 5.3. Then the nucleotide was added to both cuvettes in a small volume of buffer and the spectrum was recorded again between 320 and 250 nm. There was almost no change of the spectrum of the peptide in the presence of adenosine, guanosine, or uridine phosphate. In the presence of cytidine $2':3'$-cyclic phosphate, however, the spectral change was drastic (Fig. 3, *A*, *B*). The absorption maximum of the peptide was shifted from 274.5 to 285 nm and was quenched considerably. The spectrum of the mixture also showed a large negative peak approximately at the position of the absorption maximum of the nucleotide alone (268 nm). Addition of cytidine $2':3'$-cyclic phosphate to the 34-residue peptide and to its [Ala^{10}, Ala^{33}]-analogue which cannot form disulphide bonds, produced only a small decrease of the optical absorption of the two peptides.

The strong interaction between the 68-residue polypeptide and cytidine phosphate indicated by the UV difference spectrum (Fig. 3, *A*, *B*) was confirmed through determination of the dissociation constant of the polypeptide–nucleotide complex. Using the method of Hummel and Dreyer[14] and varying the concentration of 2′-CMP from 0.02 mM to 0.15 mM (in the presence of 0.1 mM 2′-CMP, for instance, the concentration of the polypeptide–ligand complex was 9.9×10^{-6} M and that of free polypeptide 5×10^{-7} M), the K_D was found to be 5×10^{-6} M in 0.01 M sodium acetate, *p*H 5.3 and was of the same order of magnitude as the K_D of the RNase A–2′-CMP complex[15]. By this method the 68-residue peptide bound 2′-CMP 30 times more strongly than did the 34-residue peptide.

The binding properties of the synthetic peptides were investigated further by affinity chromatography. Poly(A)–Sepharose 4B did not retard the elution of the 34-residue polypeptide but retarded considerably part of the 68-residue polypeptide applied—75% of the dimer was eluted at *p*H 5.3 at a concentration of 0.03 M to 0.07 M sodium acetate, the remaining 25% was eluted at 0.1 M to 0.24 M sodium acetate, *p*H 5.3. No differences in amino acid composition could be detected, so the two fractions may represent conformational isomers, possibly the disulphide isomers, of the synthetic 68-residue polypeptide. Poly(U)–Sepharose 4B and Blue Sepharose CL-6B, which has some affinity for proteins[16] possessing the NAD^+-binding fold[8,9], did not bind either of the two synthetic peptides.

Difference spectral measurements showed that the absorption of the mixtures of 68- and 34-residue polypeptide with double-stranded calf thymus DNA deviated only slightly from the sum of the absorptions of the separate components. The UV difference spectra obtained in the presence of single-stranded DNA, however, indicated strong polypeptide–nucleic acid interactions (Fig. 3, *C*). The main features of these spectra were a new peak with the absorption maximum at 295 nm and a depression with the absorption minimum extending from 258 to 267 nm.

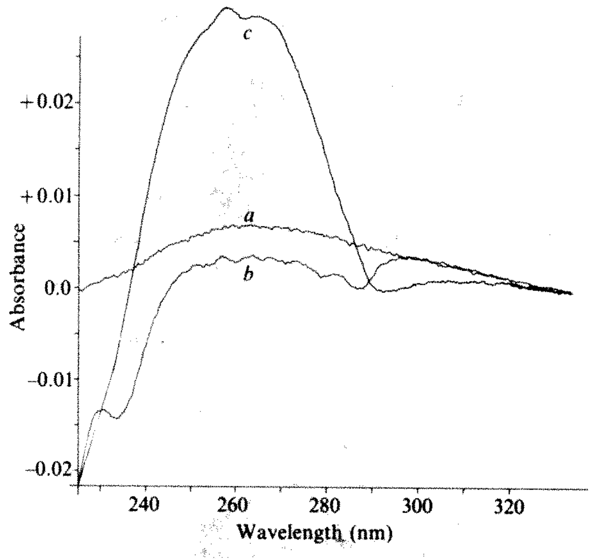

Fig. 4 Spectral evidence for the digestion of RNA by the synthetic 68-residue polypeptide. tRNA^{Phe} and 68-residue peptide were dissolved in buffer, *p*H 6.0, containing 0.1 M NaClO_4, 0.005 M sodium cacodylate, and 0.0001 M EDTA. The separate compartments of two tandem cuvettes (*d*, 0.877 cm) were filled with 0.75 ml of tRNA^{Phe} solution (0.35 μg ml^{-1}) and 0.75 ml of peptide solution (0.04 mg ml^{-1}), respectively. After recording the base line (*a*), the contents of the two compartments of one of the cuvettes were combined and the spectrum of the mixture was measured against that of the separate components immediately after mixing (*b*) and again 8 h later (*c*). The reaction took place at 22 °C.

Nuclease activity of synthetic 68- and 34-residue polypeptides

To test whether the synthetic peptides interacted with the ligand around which the model had been built, UV difference spectra of the mixtures of 68- and 34-residue polypeptide with tRNA^{Phe} in which the anticodon sequence m^2 GAA is in an exposed position were recorded.

Figure 4 shows that the spectral change observed immediately after combining solutions of 68-residue polypeptide and tRNA^{Phe} was small (curve *b*) indicating weak interaction between the two components of the mixture. However, when the spectrum was recorded again 8 h later a new broad peak with the maximum absorption at approximately 260 nm (curve *c*) was found. This type of spectral change is seen when RNA is digested by ribonucleases.

That the increase of the optical absorption around 260 nm was indeed due to a ribonuclease activity of the 68-residue polypeptide was confirmed by TLC of an aliquot of the contents of the cuvette. The digestion pattern obtained was similar to that shown in Fig. 5. In the Anfinsen assay[17,18] using tRNA from baker's yeast as substrate the specific activity of the synthetic 68-residue polypeptide was 2.5% that of natural RNase A.

Comparison of the patterns produced on digestion of tRNA by RNase A and the synthetic enzyme (Fig. 5, left and right, respectively) showed differences mainly between the products of high R_F or short chain length. This indicated that either the rates of the cleavage reactions or the substrate specificities of the two nucleases were different. Using poly(A), poly(C), poly(G) and poly(U) as substrates, differences in the cleavage rates and in the substrate specificity were indeed noticed in a semiquantitative assay. The 68-residue polypeptide digested the four polynucleotides with decreasing rates in the following order,

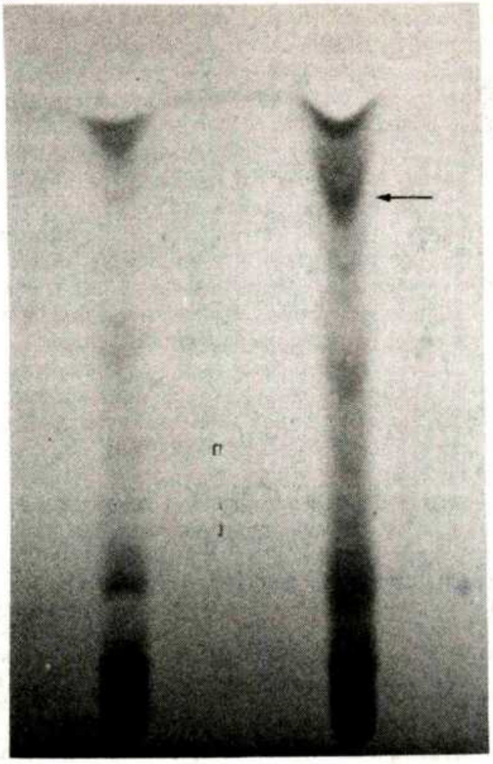

Fig. 5 TLC separation of the digestion products of tRNA produced by the action of synthetic 68-residue polypeptide (right) and natural RNase A (left). tRNA (0.20 mg each) was incubated with RNase A (0.1 μg) and 68-residue polypeptide (0.03 mg), respectively, in 30 μl of buffer, pH 6.0, at 22 °C. Aliquots (3 μl) of the reaction mixtures were chromatographed every 12 h until the digestion patterns remained unchanged (the patterns shown were obtained after a 93.5-h reaction time). Chromatograms were developed on silica gel F_{254}-coated thin layer plates in isopropyl alcohol/ammonium hydroxide/water (14:1:5). Spots were detected under UV light. The arrow indicates the position of free cytidine 2′:3′-cyclic phosphate. A control of undigested tRNA (not shown) gave a single spot at the origin. The buffer for the incubations contained 0.1 M $NaClO_4$, 0.005 M sodium cacodylate, and 0.0001 M EDTA, adjusted to pH 6.0.

poly(C) ≫ poly(A) > poly(U) ≫ poly(G). Using RNase A as enzyme, this order became poly(C) > poly(U) ≫ poly(A); poly (G) was not cleaved at all. The fact that cytidine phosphates were bound tighter by the 68-residue polypeptide than other nucleotides was reflected by the relatively fast depolymerisation of poly(C) in the presence of the synthetic enzyme. The nucleoside 2′:3′-cyclic phosphates seemed to be the final digestion products. The maximum of the rate of depolymerisation was between pH 6 and pH 8. But even in 0.1 M formic acid the 68-residue polypeptide had considerable nuclease activity; in identical conditions 0.1 M formic acid alone did not hydrolyse poly(C).

The activity of the two fractions obtained by affinity chromatography of the 68-residue polypeptide on poly(A)–Sepharose 4B was the same within the limit of error of the assay method using tRNA as substrate. Whether the tighter-binding fraction that eluted at sodium acetate concentrations of 0.1 to 0.24 M had increased nuclease activity towards poly(A) has not been tested.

The 34-residue polypeptide possessing one intramolecular disulphide bond was less than 4% as active as the 68-residue polypeptide. This was probably because of weaker binding of nucleic acids by the monomer. As controls, insulin and bovine serum albumin were completely inactive in these assays.

In assays for proteolytic (tryptic, chymotryptic, peptic) and glycolytic (lysozyme) activity both the 68- and the 34-residue polypeptide were inactive.

The possibility that the low ribonuclease activity of the 34-residue polypeptide might be due to incomplete separation from the more active 68-residue peptide was excluded by preliminary results obtained with an [Ala^{10}, Ala^{33}]-analogue of the 34-residue polypeptide. The nuclease activity of this analogue suggested that the disulphide bond was not essential for the structure and biological function of the 34-residue polypeptide and that the amino acid sequence chosen from model building could indeed fold in such a way as to allow interactions with nucleotides and nucleic acids. Dimerisation of the Cys-containing monomer through formation of two intermolecular disulphide bonds, however, seemed to produce a cleft or pocket in which the essential groups were in a more favourable position for binding and catalysis.

Chemical modification has been used successfully to determine active site residues and to propose catalytic pathways of ribonucleases[19]. Thus, iodoacetic acid was found to carboxymethylate at pH 5.5 the side chains of His 119 and His 12 of RNase A[20] and of Glu 58 of RNase T_1[21] to give inactive enzymes. When the synthetic 68-residue polypeptide was submitted to similar conditions[20] for 12 h, no carboxymethylation of the positively charged amino acid residues (Lys 28, His 32) took place as determined by electrophoresis and by amino acid analysis of an acid hydrolysate. The electrophoretic mobility of the 68-residue polypeptide, incubated with iodoacetic acid, on cellulose-coated thin layer plates in 1.2 M formic acid, 2 M urea, pH 2.2, was unaltered and no N^1- or N^3-carboxymethylhistidine was detected by amino acid analysis. Carboxymethylation of the 68-residue polypeptide at pH 8 gave identical results. However, alkylation of the side chain of Asp 7 or Glu 23 would have gone undetected by these methods. Therefore, the reaction was repeated using iodo[2-^{14}C]acetic acid. After 17 h at pH 5.75 only 1 out of 50 protein molecules seemed to be labelled. This was consistent with the result of the nuclease assay in which there was no noticeable loss of activity of the 68-residue polypeptide after iodoacetic acid treatment. Thus the geometry of the active site of the synthetic enzyme is apparently different from that of the active sites of RNase A and RNase T_1.

CD spectra of the synthetic polypeptides

To establish whether the synthetic peptides adopted the hypothetical secondary structure in aqueous solution spectral analyses were performed. The predicted structure (Fig. 1, I) suggested pronounced Cotton effects between 185 and 230 nm. In addition, the presence of phenylalanine and tyrosine residues in the NH_2-terminal region of the peptides could give rise to

Table 1 Amino acid composition of synthetic 34-residue polypeptide

	Expected	Protected peptide resin	Purified peptide
Asp	4	4.5	4.2

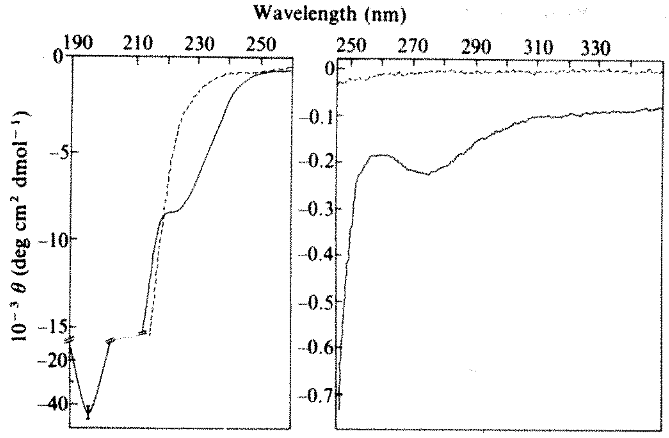

Fig. 6 CD spectrum of the 34-residue peptide. Measurements in the near and far UV region were carried out in a Dichrographe II with high sensitivity accessory and thermostated cuvette compartment using 0.1 mm to 10 mm cells. To determine molar concentrations absorption spectra were monitored in a Zeiss DMR 10 spectrophotometer. The peptide was dissolved in 0.01 M sodium citrate, *p*H 5.3 (solid line), and in 0.001 M sodium citrate–6 M guanidinium hydrochloride (dashed line), respectively.

dichroic absorption in the range of aromatic absorption at ~280 nm.

The 68-, 34-, and [Ala^{10}, Ala^{33}]-34-residue polypeptides showed similar optical properties in the aromatic region. In the far UV the presence or absence of cystine residues generated quantitative differences. A helical contribution was represented by a minimum at ~222 nm. Other characteristic features of protein CD spectra seemed to be shifted towards the UV region giving rise to a second minimum at 197 nm. The corresponding maximum was below 185 nm. A representative example is given in Fig. 6 (solid line) illustrating the overall CD profile of the 34-residue polypeptide. On addition of 6 M guanidinium hydrochloride (Fig. 6, dashed line) the CD bands in the aromatic absorption range and in the far UV region of the spectrum disappeared indicating a marked decrease in original secondary structure. Quantitative evaluation of helix, β-structure, and β-turn contents was not possible because of the specific interactions within the relatively small polypeptide molecule. Experiments dealing with solvent effects and ligand binding will be published elsewhere[22].

Discussion

Two problems must be solved before it becomes possible to design artificial proteins with novel properties for laboratory, medical and industrial use. First, assembly of the secondary structural elements to give the biologically active tertiary structure is at present only poorly understood; and second, chemical synthesis of proteins is still extremely difficult if not impossible. However, it is reasonable to assume that these obstacles will be overcome. Artificial proteins could also be produced by a genetic approach through expression of synthetic genes in bacteria[23]. An alternative route to artificial proteins is the thermal copolymerisation of amino acids yielding a mixture of proteinoids of varying composition and size. Such polymers have non-random amino acid composition[24] and are capable of catalysing chemical reactions such as hydrolysis, decarboxylation or amination[25]. Although the catalytic activities are weak, some thermal polyanhydro-α-amino acids do show substrate specificity and stereoselective action[25]. Isolation from the proteinoid mixture of single species possessing interesting enzymatic properties may be a formidable task and has not yet been reported.

Reproducible preparation of artificial proteins with distinct properties can probably best be achieved by a planned synthesis. An example for the latter approach is the synthesis by Chakravarty *et al.*[26] of an active lysozyme model consisting of only 10 amino acid residues. Based on the work of Kotelchuck and Scheraga[27], Chakravarty *et al.* designed a decapeptide that, aided by the polymeric nature of the substrates used, could adopt α-helical conformation displaying the essential unionised and ionised carboxyl groups in a suitable environment. This decapeptide showed weak glycosidase activity.

In the nucleic acid-binding polypeptide described here it is likely that stacking of the aromatic side chains with the bases of the nucleotides and hydrogen bonds in a hydrophobic environment contributed to the interaction energy. As the synthetic peptide was neutral, it possibly resembled in its properties several of the non-histone chromosomal proteins. The fact that cytidine phosphates were bound with relatively high specificity whereas interaction with the trinucleotide sequence around which the model has been built was weak, may have been due to differences between the proposed and the actual folding of the synthetic polypeptide. Preliminary CD measurements showed distinct CD bands in the aromatic and in the far UV absorption range that were extinguished in the presence of 6 M guanidinium hydrochloride. To determine secondary and tertiary structure more precisely we shall attempt crystallisation of the 34-residue polypeptide.

The synthetic nucleic acid-binding polypeptide also had ribonuclease activity with high preference for the cleavage of 3′,5′-phosphodiester bonds following 3′-linked cytidine residues. Dimerisation of the 34-residue polypeptide through formation of two intermolecular disulphide bonds improved the binding of cytidylic acid and enhanced the ribonuclease activity. This activity was not caused by microbial contamination since proteins such as insulin and bovine serum albumin were completely inactive in the nuclease assays after they had been passed through the same columns that were used for the purification of the synthetic polypeptides. As nucleases like RNase T$_1$, RNase A, or staphylococcal nuclease are among the shortest enzymes known, their action may be more easy to simulate by designed synthetic models than that of larger and more complex enzymes. Furthermore, the presence of a histidine residue in a position favourable for catalysis may have been essential for the nuclease activity of the 34-residue polypeptide because histidine residues are frequently found in the active site of hydrolytic enzymes.

We thank Professor M. Eigen and Drs W. Kullmann and D. Labuda for discussions and Professor R. Jaenicke for the CD measurements. This work was supported in part by the Stiftung Volkswagenwerk and by the Deutsche Forschungsgemeinschaft.

X-ray and [Fe XIV] 5,303 Å emission from Puppis A supernova remnant

Hiroshi Itoh

Department of Astronomy, University of Kyoto, Sakyo-ku, Kyoto 606, Japan

Recently, Lucke *et al.*[1] found [Fe XIV] 5,303 Å emission from Puppis A to be much less intense than that expected from the X-ray data given by Zarnecki *et al.*[2]. We propose here that this discrepancy can be removed by taking into account the nonequilibrium state of ionisation within the X-ray source.

Interpreted under the assumption of ionisation equilibrium, the X-ray spectrum of Pup A consists of two components which have temperatures of 13 and 2.5×10^6 K (ref. 2). Therefore, if ionisation equilibrium indeed holds, the low-temperature plasma should emit [Fe XIV] 5,303 Å photons as observed in the solar corona. However, the measured [Fe XIV] emission[1] has been too weak to be in harmony with the volume emission measure[2] of the low-temperature plasma. Lucke *et al.*[1] have argued that the most plausible way of reducing this discrepancy to within experimental error is probably by assuming the maximum temperature of 3×10^6 K allowed by the X-ray data[2]. This interpretation, however, does not seem to be tenable, since ionisation equilibrium is unlikely to hold within the X-ray source. In fact, from a calculation[3] of time-dependent ionisation of oxygen for a post-shock temperature of 2.8×10^6 K, the time scale τ_I for ionisation relaxation within the low-temperature plasma is estimated to be $3\times10^4/n_e$ yr, where n_e ($\mathrm{cm^{-3}}$) is the post-shock electron density and has been estimated[4] to be about 8 $\mathrm{cm^{-3}}$; it can readily be shown that this value for n_e assures approximate pressure balance[5] between the low-temperature plasma and optical filaments[6,7]. We may then set $\tau_I\approx4\times10^3$ yr for the low-temperature plasma. On the other hand, a sure upper limit to the remnant's age, τ, can be obtained from the inequality, $\tau<r/v_b$, where r is the radius of Pup A which may be set equal to $7.3d$ pc (ref. 4), d (kpc) being the distance of Pup A, and v_b is the shock velocity of the blast wave propagating through the local intercloud medium with a density n_0 of about 0.1 H atom $\mathrm{cm^{-3}}$ or less[4]. Assuming approximate pressure balance between the low-temperature plasma and the blast wave, we may write $v_b\approx v_s(n_e/4n_0)^{1/2}$ (ref. 5), where v_s is the velocity of the shock producing the low-temperature plasma and is about $4.5\times10^7\ \mathrm{cm\ s^{-1}}$. Thus, we obtain $\tau<4\times10^3(n_0/0.1)^{1/2}\,d$ yr. Since $n_0\leqslant0.1$ H atom $\mathrm{cm^{-3}}$ and $d=1.2$–2.2 kpc (ref. 4), the condition for ionisation equilibrium, $\tau_I\ll\tau$, can hardly hold within the low-temperature plasma. A similar consideration for the high-temperature plasma which has a temperature of 13×10^6 K also leads to the same conclusion. Therefore, it seems more useful to examine a nonequilibrium ionisation model.

Recent calculations[8] of the time-dependent ionisation and X-ray emission of supernova remnants have shown that the nonequilibrium state of ionisation within the X-ray source results in an enhancement of the X-ray emission in the energy range below 1 keV, causing a two-component appearance of the X-ray spectrum. Although this result was obtained by assuming a uniform interstellar medium, it will hold qualitatively in the case of Pup A where the dominant X-ray source may be a shock-heated interstellar cloud[4]. The nonequilibrium ionisation model will predict much less [Fe XIV] emission than the equilibrium model, since in the former the X-ray emission in the sub-keV range is not ascribed to a plasma favourable to the [Fe XIV] emission.

We now evaluate the [Fe XIV] luminosity of the shock wave responsible for the X-ray emission from Pup A. After passing through the shock front, the electrons are rapidly heated and successively ionise the ions to higher stages[8]. The electron temperature of about 10^7 K inferred from the X-ray spectrum[2] indicates that the iron atoms would be almost stripped of their M-shell electrons under ionisation equilibrium[9]. Therefore, on its way to the equilibrium state, every iron atom passes through the stage of $\mathrm{Fe^{+13}}$. The average time interval during which an iron atom stays in this stage is $(n_e C)^{-1}$ seconds, where C ($\mathrm{cm^3\ s^{-1}}$) is the total coefficient for direct ionisation[10] and autoionisation[11] of $\mathrm{Fe^{+13}}$ by electron impact. Recombinations can be safely ignored in rapidly ionising plasmas. Also, because $(n_e C)^{-1}$ is of the order of only 10^9 s, changes in the electron temperature and density during this time interval can be ignored. Thus, after passing through the shock front, an iron atom emits $(n_e\alpha_e+n_p\alpha_p)\,h\nu/(n_eC)$ erg on the average at [Fe XIV], where n_p ($\mathrm{cm^{-3}}$) is the proton density, $h\nu$ (erg) is the photon energy, and α_e and α_p ($\mathrm{cm^3\ s^{-1}}$) are the coefficients for collisional excitation by electrons[12] and protons, respectively; for relatively high proton temperatures relevant to our case, α_p should be calculated from the cross-section data[13,14]. By assuming that the shock front has an area of 10^2S $\mathrm{pc^2}$ and is propagating at a speed of $10^8\,v\ \mathrm{cm\ s^{-1}}$ into a medium with a density of n_1 H atom $\mathrm{cm^{-3}}$ and an iron abundance of $4\times10^{-5}A$ in number relative to hydrogen[15], the [Fe XIV] luminosity of the shock wave may be written as

$$L=1.4\times10^{32}An_1vSR\ \mathrm{erg\ s^{-1}} \tag{1}$$

where

$$R=0.1\times[\alpha_e+(n_p/n_e)\alpha_p]/C \tag{2}$$

In Pup A, An_1v is probably near unity[1,4], while the value of S is uncertain. Referring to an estimate[4] that a fraction 0.1 of the total volume of Pup A is emitting in X-rays, we write $S=0.1^{2/3}\times4\pi\,(0.73d)^2\times s=1.4sd^2$, where s is a correction factor. The quantity R defined by equation (2) depends on the electron and proton temperatures in the [Fe XIV] emission region. If the electron and proton temperatures are quickly equilibrated just behind the shock front, we may adopt a single temperature of 10^7 K inferred from the X-ray spectrum[2]. In this one-fluid case, $R=0.81$ when $n_p/n_e=0.85$ (ref. 15), and equation (1) yields $L=1.6\times10^{32}An_1vsd^2\ \mathrm{erg\ s^{-1}}$. On the other hand, if the electrons are not heated significantly at the shock front compared with the protons, we should adopt a lower electron temperature and a higher proton temperature than 10^7 K since [Fe XIV] emission originates nearer to the shock front than X-ray emission. Inspection of the results of our recent calculations[8] gives electron temperatures of about 5×10^6 K for the $\mathrm{Fe^{+13}}$ region. The proton temperature need not be evaluated accurately, since α_p attains a maximum value of $4.1\times10^{-9}\ \mathrm{cm^3\ s^{-1}}$ at a temperature of 3.2×10^7 K and is very insensitive to the proton temperature in the range $(1–10)\times10^7$ K. We set $\alpha_p=4\times10^{-9}\ \mathrm{cm^3\ s^{-1}}$. In this two-fluid case, $R=1.9$, and equation (1) yields $L=3.7\times10^{32}An_1vsd^2\ \mathrm{erg\ s^{-1}}$. Thus, in both the one-fluid

0028-0836/79/430656—02$01.00

case and the two-fluid case, the nonequilibrium ionisation model predicts a [Fe XIV] luminosity that is of the same order as the observed[1,16] values of $(1\text{–}5)\times10^{32}\,d^2\,\mathrm{erg\,s^{-1}}$. Also, a similar calculation of [Fe X] 6,374 Å emission predicts that the [Fe X]/[Fe XIV] luminosity ratio is 0.14 in the one-fluid case or 0.098 in the two-fluid case, in accordance with an upper limit of 0.3 derived from the observation[1].

Thus the discrepancy found by Lucke *et al.*[1] between the X-ray and [Fe XIV] data on Pup A can be removed by the nonequilibrium ionisation model for the X-ray emission from this object. Note that the bulk of the observed [Fe XIV] emission need not be ascribed to a rapidly ionising plasma behind the shock front of the X-ray source. For instance, the brightest [Fe XIV] emission region observed near the edge of the radio shell seems, because of its high surface brightness, to have been produced by the interaction of the shock front with a density inhomogeneity[1], which contributes little to the X-ray emission. If that is the case, the [Fe XIV] emission from this region may be analysed under the assumption of ionisation equilibrium, since at the post-shock temperature of about 3×10^6 K the ionisation state of iron relaxes to the equilibrium much faster than that of oxygen[17]. Future observations with better spatial and spectral resolution will be important in clarifying the nature of the [Fe XIV] emission from Pup A.

Hydrogen evolution from water induced by visible light mediated by redox catalysis

John Kiwi & Michael Grätzel

Institut de Chimie Physique, Ecole Polytechnique Fédérale, Lausanne, Switzerland

Noble metal dispersions are suitable for mediating light-induced hydrogen[1–5] and oxygen[6–8] evolution from water. We report here a dramatic improvement of the hydrogen production rate when very finely dispersed platinum is used as a mediator in reaction (1). The first observations of the dynamics of intervention of the Pt particles in the redox events are presented. A centrifuged colloidal Pt catalyst stabilised by polyvinyl alcohol showed exceptionally high activity in promoting hydrogen evolution from water via

$$2\mathrm{MV}^{+}+\mathrm{H_2O}\xrightarrow{\mathrm{Pt}}\mathrm{H_2}+2\mathrm{OH}^{-}+2\mathrm{MV}^{2+}\qquad(1)$$

where MV^{+} stands for reduced methylviologen. The latter is produced photochemically in aqueous solution containing $\mathrm{Ru(bipy)_3^{2+}}$ as a sensitiser and EDTA as an electron donor. At 10^{-3} M Pt the reoxidation of MV^{+} requires only 15 μs and leads to quantitative formation of $\mathrm{H_2}$.

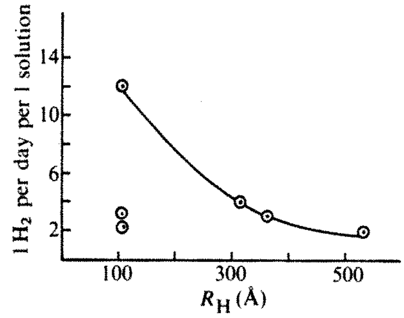

Fig. 1 Correlation for the observed yields for $\mathrm{H_2}$ in the system $\mathrm{Ru(bip)_3^{2+}}$ 4×10^{-5} M, MV^{2+} 2×10^{-3} M, EDTA 3×10^{-2} M at *p*H 5 and the radius of the catalyst particles used. Pt–PVA–60,000 catalysts centrifuged at 20,000 r.p.m. were used containing 3.5 mg Pt per 25 cm³ of solution.

The Pt/PVA catalyst was prepared by a procedure outlined by Nord[9]. By centrifuging this preparation at different speeds and for different times particle sizes between 530 and 110 Å are determined by quasi-elastic light scattering. The polymer PVA molecules are adsorbed on the surface of Pt metal through their less polar groups. The polymer also hydrates strongly in the presence of water due to its own OH groups. As long as the surface coverage is not complete, $\mathrm{H_2O}$ can penetrate to the Pt and the catalysis is mediated by a lyophobic system. In the case of particle size with radius 110 Å the size of the PVA particle on which the Pt is deposited is equal to the polymer PVA–60,000 indicating that there is a good dispersion of Pt on the polymer.

Steady-state irradiations were carried out with a 450 W xenon lamp through 400 nm cut-off filter and a water filter to eliminate IR radiation. Hydrogen was analysed by conventional GC with a molecular sieve 5 Å column. A detailed account of the light-induced events leading to irreversible reduction of (1'1-dimethyl-4,4'-bipyridinium^{+2}, abbreviated to MV^{+2}) to MV^{+} and oxidation of EDTA has been given elsewhere[3,4]. In the presence of colloidal Pt, MV^{+} reoxidises with simultaneous evolution of $\mathrm{H_2}$.

Figure 1 shows that a decrease of the particle radius from 500 to 100 Å leads to a drastic increase in the hydrogen evolution rate which is as high as 12 l per day per l solution for the smallest particle size. In the latter case, the bubbling of hydrogen gas which occurs when the solution is illuminated is readily seen. In Fig. 1 the common feature is the Pt content of the solutions of different particle size, namely 3.5 mg Pt per 25 cm³. Figure 1 also shows two extra points with 100 Å particle size but with low Pt levels; 0.35 mg Pt per 25 cm³ solution, the upper one, and 0.25 mg Pt per 25 cm³ solution, the lower one. The yields of $\mathrm{H_2}$ are 5 and 6 times, respectively, less than if 3.5 mg Pt per 25 cm³ solution is photolysed as shown in Fig. 1.

These observed size effects may be explained by the fact that the Pt particles intervene as microelectrodes[10–12] in the hydrogen evolution reaction (1). Electron transfer from MV^{+} to the Pt particles regulates these microelectrodes cathodically until $\mathrm{H_2}$ formation can take place. A smaller electrode size is advantageous both from the point of view of mass transport of the electroactive species as well as surface area per g of catalyst used. Note that in our experimental conditions the speed of electron turnover in the $\mathrm{MV}^{+}/\mathrm{MV}^{2+}$ relay—and not the photon flux or the kinetics of MV^{2+} photoreduction—is rate determining in the hydrogen generation process. The quantum yield for $\mathrm{H_2}$ formation was found to be half of that for MV^{2+} reduction, $\phi(\mathrm{H_2})=0.13$. This implies that the reoxidation of MV^{+} strictly follows the stoichiometry indicated in equation (1).

A further advantage of the centrifuged Pt/PVA is that the solutions remain completely transparent even at high catalyst concentration. This allows the direct study of the dynamics of the reaction of MV^{+} with Pt particles by laser photolysis. Figure 2*a–c* illustrates the temporal behaviour of the characteristic

0028-0836/79/430657—02$01.00

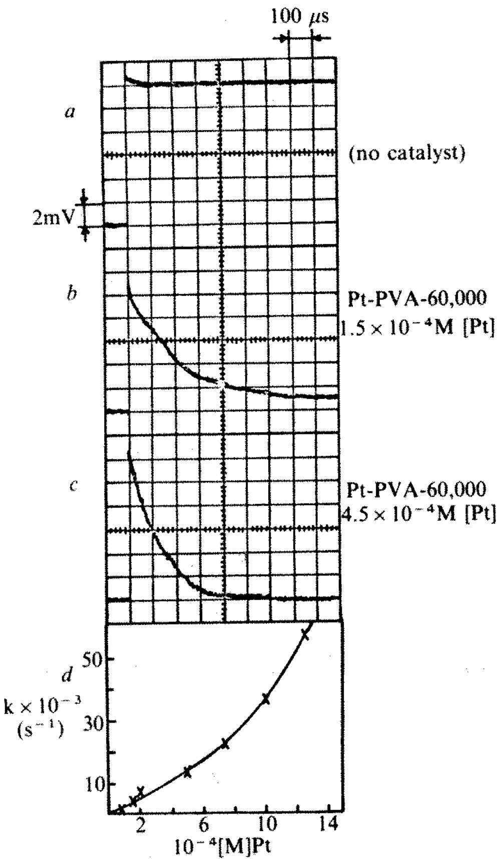

Fig. 2 Effect of the Pt–PVA catalyst concentration on the behaviour of MV^+ absorption at 600 nm. Representative oscilloscope traces are included in *a*, *b*, *c*. *d*, The rate constants for MV^+ decay are plotted against platinum concentration of the Pt–PVA catalyst used.

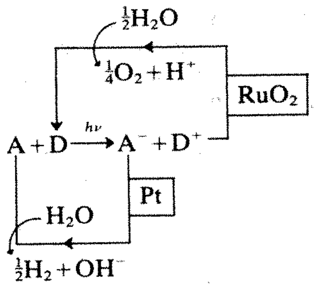
MV^+ absorbance at 602 nm in the absence and presence of catalyst. The upward deflection of the signal after the laser pulse is due to the formation of MV^+ via the photo redox process[3] sensitised by $Ru(bipy)_3^{2+}$. In the absence of catalyst the MV^+ absorption is stable, addition of colloidal Pt induces a decay of the signal the rate of which increases sharply with Pt concentration. Fitting the absorbance decay curves to an exponential time law gives the rate constants which are plotted as a function of Pt concentration in Fig. 2*d*. The curve is steeper than linear, indicating that the reaction order is greater than one with respect to the Pt concentration.

At a concentration of 10^{-4} M Pt in Pt–PVA–polymer, we observe a rate constant $k = 0.14 \times 10^3\ s^{-1}$. At the highest concentration of catalyst (12.5×10^{-4} M Pt content), the rate was $5.7 \times 10^4\ s^{-1}$. The lifetimes observed for MV^+ were shortened from about 7,000 μs to 15 μs, when the concentration of catalyst varied only by a factor of about 12.

The minimum concentration of platinum which gives efficient recycling of MV^+ under steady-state illumination is 0.5×10^{-4} M. The lowest useful concentration necessary to detect measurable quantities of photo-produced H_2 is 0.1×10^{-4} M in Pt (0.05 mg Pt per 25 cm^3). In this case, the evolution of H_2 observed was 0.010 l H_2 per day per l solution, but a noticeable amount of hydrogen gas bubbling out of solution could only be observed at 5 times the concentration of Pt necessary for the onset of H_2 evolution. Evidently, such a Pt content is sufficient to reoxidise the MV^+ rapidly enough to avoid a significant build up of MV^+ concentration. An onset value for the amount of Pt present seems necessary to obtain reasonable rates of H_2 evolution (see Fig. 1). The value for this onset is about 0.5 10^{-4} M Pt and the recycling at higher concentrations of Pt is shown in Fig. 2*b*, *c*.

These results are important for photo-redox splitting of water into hydrogen and oxygen:



it seems that by using a suitable catalyst, the conversion of A^- into A and simultaneous formation of hydrogen can be accomplished so rapidly that it can compete efficiently with the thermal backreaction. (In the photostationary state achieved under sunlight irradiation, the latter process, due to its bimolecular nature, should require at least several milliseconds.) Moreover, redox catalysts such as colloidal RuO_2 have been shown[7,8,13] to mediate very effectively the back conversion of D^+ into D under simultaneous production of oxygen. In fact, in a mixture of RuO_2 and Pt colloids serving as selective microelectrodes for the A/A^- and D^+/D redox couples, light-induced water splitting in a two-component system has recently been observed[13].

Detection of elastic strain in an amorphous polymer by X-ray scattering

M. Pick*, R. Lovell & A. H. Windle

Department of Metallurgy and Materials Science,
University of Cambridge, Cambridge, UK

For crystalline solids, the displacement of diffraction peaks with applied elastic strain is the basis of one method of measuring internal stress[1,2]. The effect has been exploited for both metals[3] and crystalline polymers[4]. Hitherto, the diffuse character of diffraction peaks obtained from non-crystalline materials has discouraged similar measurements on them. Working with atactic polymethyl methacrylate (a-PMMA) as an example of non-crystalline polymer glasses (which can sustain elastic strains up to several per cent before plastic yield or fracture), a displacement of the most intense diffraction peak has been observed in response to applied elastic strain. This peak corresponds to intermolecular correlations in the polymer[5,6].

0028–0836/79/430658—02$01.00

X-ray diffraction scans from a-PMMA show three broad peaks of heights which decrease in order of increasing diffraction angle. Using CuKα radiation, the maxima are at 13°, 30° and 42° $2\theta_B$. (These angles correspond to Bragg spacings of 6.8, 3.0 and 2.2Å respectively, which, of course, for a non-crystalline material have limited meaning.) Orientation of the PMMA glass by plastic deformation demonstrates that the major component of the first peak is equatorial and represents intermolecular correlations, whereas the 30° and 42° peaks concentrate on the meridian and are intramolecular in origin[5,6].

Dumbbell shaped tensile specimens, cut from 1 mm thick sheet (ICI Perspex), were stressed at room temperature and held at constant elastic strain. The maximum extension obtained before fracture was ~11%. Diffraction scans of the strained specimens were obtained using a standard transmission diffractometer. Examples for a specimen strained to ~8.8%, with the scattering vector first parallel to and then perpendicular to the tensile axis, are shown in Fig. 1. Also included for comparison is the diffraction scan for an undeformed specimen. As can be seen, the principal effect is a strain-induced displacement of the first peak. It moves to a lower angle when the scattering vector is parallel to the tensile axis, and to a higher angle when the vector is normal to the axis.

The fact that the positions and intensities of the second and third peaks, which are sensitive to molecular conformation[6], are not significantly affected by elastic strain indicates that for this polymer the underlying conformation does not change in response to the applied stress. There is also no suggestion of orientation of the molecular axes as a result of elastic strain, although this commences once the polymer yields and leads to an intensification of the second and third diffuse peaks on the meridian[7].

Figure 2 shows the displacement of the first peak as a function of applied elastic strain. The right hand ordinate expresses the percentage change in interchain spacing as determined by the change in cosec θ_B.

For a crystalline solid the most appropriate simple model would be one in which the material deforms affinely, that is the chain segments move as though embedded in a continuum. Such a model predicts a change in the interchain spacing equal to the applied strain. However, for PMMA the X-ray measurements of the microscopic strain give values which, although in the same sense, are much smaller than the strains applied. A tensile strain of 10% produces an increase in interchain spacing of only 1.7%, whereas the associated lateral compressive strain which, for PMMA with a poissonian ratio of 0.39, will be 3.9% apparently corresponds to a decrease in interchain spacing of 1.1%. The microscopic strains are thus, 17% and 28% respectively, of the applied strain.

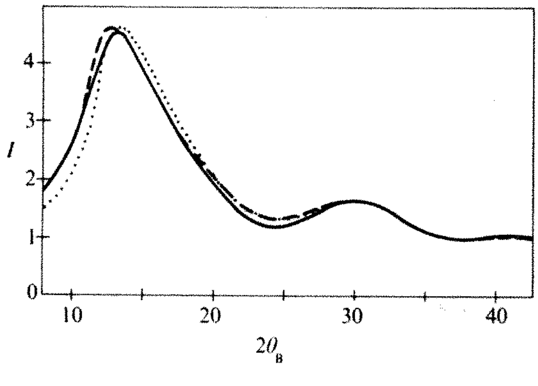

Fig. 1 Comparison of diffracted intensities for scans: dashed line, scattering vector parallel to the applied tensile stress; dotted line, perpendicular to the stress; solid line, for the unstressed specimen. The applied tensile elastic strain was 8.8%.

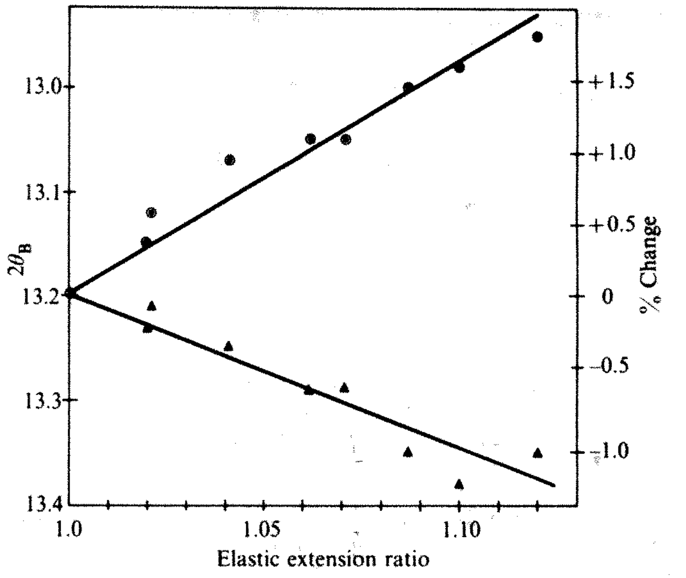

Fig. 2 The change in position of the first broad diffraction peak as a function of elastic strain. ⊙, Scattering vector parallel to the applied tensile stress; ▲, perpendicular. The right-hand ordinate is calibrated in terms of the change in apparent chain spacing.

The other simple model is one in which the microscopic strain is solely due to the increase in volume of the material (caused by the hydrostatic component of the tensile strain). While this predicts a change in interchain spacing of approximately the correct amount (10% tensile strain giving ~1% increase in interchain spacing for PMMA), it is unable to account for the fact that the change normal to the tensile axis is a decrease.

These discrepancies suggest that a more appropriate model may be a non-affine one in which the distance between nearest-neighbour chains remains essentially constant. For PMMA, which has a fairly rigid backbone, such contacts may involve some correlation of segmental orientation. However, even without such correlation, the distance between nearest-neighbours initially in contact is likely to change less under stress than will the distance between near-neighbours which are not in contact. Since it is the nearest-neighbour contacts which have a dominant influence on the position of the intermolecular diffraction peak, such a model would explain the reduced sensitivity of peak position to applied strain. At the same time, the volume increase and macroscopic strain would be accounted for by a change in the number and arrangement of the near-neighbour chains.

The fact that there is still no satisfactory model to describe molecular packing in non-crystalline polymers means that these arguments cannot be developed further and quantified. Also, any detailed understanding will have to take into account the thermally activated (anelastic) component of the applied strain which is associated with changes of local molecular orientation, or of sidegroup geometry, which themselves will influence packing.

We thank Geoff Mitchell for discussions and support, Professor R. W. K. Honeycombe for facilities, and the SRC for financial support.

Radiative cooling near the mesopause

D. C. Allen*, J. D. Haigh†, J. T. Houghton† & C. J. S. M. Simpson*

* Physical Chemistry Laboratory, Oxford University
† Department of Atmospheric Physics, Clarendon Laboratory, Oxford University, UK

The heat budget of the region of the upper atmosphere near the mesopause at ~85 km is determined by a balance between radiative, photochemical and dynamical effects leading to a very cold polar mesopause in the summer and a comparatively warm mesopause in the winter. There is a temperature minimum at the mesopause primarily because of the strong radiative cooling which occurs due to thermal emission by carbon dioxide in its ν_2 vibrational band at 15 μm wavelength. Above 80 km this band is no longer in local thermodynamic equilibrium (LTE) so the amount of cooling depends critically on the rate at which CO_2 molecules are excited or relaxed by collision. Any estimate of radiative cooling for this region of the atmosphere, therefore, relies on knowledge of the collisional relaxation time, τ. The importance of the temperature dependence of τ was pointed out by Houghton[1]. Previous calculations used a wide range of values because no direct measurements of τ had been made in the appropriate temperature range. We show here that the effect on cooling rate calculations of using values of τ measured at temperatures down to 175 K. We also estimate a radiative relaxation time for the atmosphere near the mesopause and are able to draw conclusions as to the natural lifetime of any temperature perturbation at this altitude.

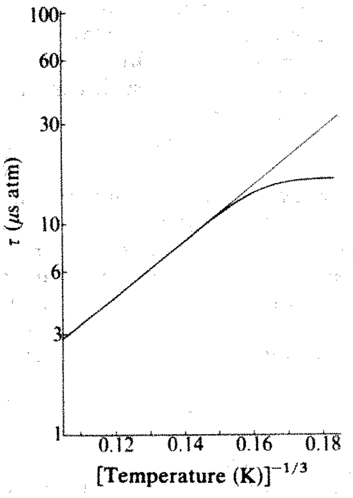

Fig. 1 The relaxation time of the ν_2 vibration of CO_2 due to CO_2–N_2 collisions. The thin line shows a linear extrapolation of the higher temperature measurement.

The CO_2 molecules may be excited into the ν_2 state by the N_2, O_2 and O atoms present. Water is a very effective collision partner, but in the upper atmosphere its effect is negligible owing to its very low concentration. In previous calculations of cooling rates[1–4], values of the relaxation time, τ, at 1 atm between 2 and 50 μs have been used.

The reason for this spread was because of the difficulties in making reliable estimates of τ. A scatter of at least ±25% existed in the older data at 300 K[4] and it was not known whether the nearly linear plots of log τ against $T^{-1/3}$ could be extrapolated down to 180 K. For instance, on the basis of data for the relaxation time of CO_2 by CO_2 and by Ar taken down to 150 K[6], perhaps the best estimate of the relaxation time of CO_2 by air at 210 K to be made up to the present was 22 μs (ref. 7).

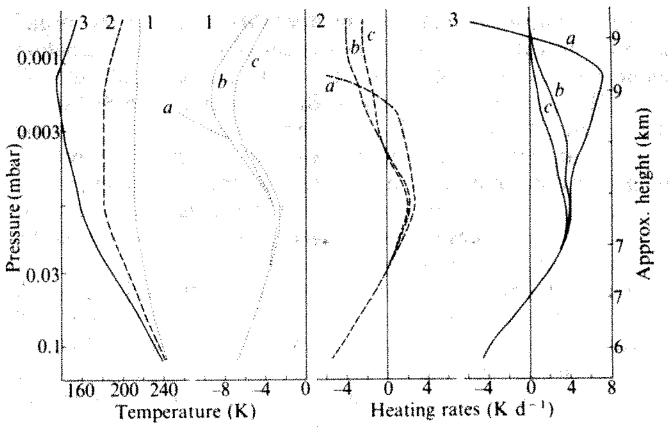

Fig. 2 Temperature profiles for (1) January at latitude 70 °N; (2) USA 1962 Standard Atmosphere; (3) December at latitude 70 °S. And the corresponding heating rates assuming (*a*) local thermodynamic equilibrium, (*b*) the new measurements of τ, (*c*) τ values from extrapolation of measurements at higher temperatures.

Figure 1 shows the results of recent laser fluorescence measurements of the relaxation time of the ν_2 vibration of CO_2 due to CO_2–N_2 collisions. Further details of these measurements are given by Allen[8]. They are the first direct measurements over the range of temperature appropriate to the mesopause region, and show much less dependence on temperature at temperatures below 250 K than would be expected from an extrapolation of the higher temperature data. On the basis of the work of Simpson *et al.*[7] we anticipate that the relaxation time for CO_2 by O_2 will be about 20% faster than for CO_2 by N_2. For air at 180 K this gives $\tau = 15 \pm 2$ μs at 1 atm, that is, 30% less than the previous best estimate.

In Fig. 2 the effects of different values of τ on the radiative divergence near the mesopause are calculated using the Curtis matrix method as described by Williams[4] and Houghton[9]. This method allows for transfer of radiation between different levels of the atmosphere and for the breakdown of local thermodynamic equilibrium: the transmission function incorporates the Curtis–Godson approximation, a constant diffusivity factor and a band model of independent lines. Note that an additional radiative cooling of ~2 K d^{-1} arises from the difference between

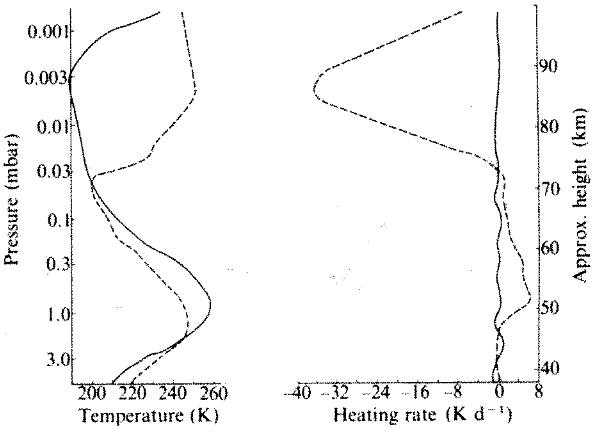

Fig. 3 Solid lines show approximate radiative equilibrium temperature profile calculated for latitude 30 °N in January and its corresponding heating rate. Dashed lines show an extreme temperature profile measured from a rocket[8] and its corresponding heating rate.

0028-0836/79/430660—02$01.00

using straight extrapolation and using the latest values. In the absence of other heating mechanisms this would have to be balanced by dynamical heating due to an increase in downwards motion of about 200 m d^{-1}—a very significant consideration in the context of the mesospheric circulation.

Another quantity which is important in understanding the structure of the mesosphere especially in perturbed conditions is the time constant with which radiation processes tend to return a perturbed atmosphere to the mean state. Figure 3 shows a radiative equilibrium temperature profile calculated for latitude 30 °N in January using the Curtis matrix method, with the new τ values, and for the 15 μm CO$_2$ cooling and an 'exact' frequency dependent calculation for the heating due to absorption of solar UV radiation by ozone and molecular oxygen. Also shown is a rather extreme temperature profile similar to one measured on 4 January 1976 by some rockets[10]. Other data in the same series suggest that this profile persisted for some while being part of a wavelike disturbance with period 7 or 12 days. The net radiative heating rate was calculated for the latter profile using the methods referred to above. It shows a cooling of 36 K d^{-1} where the temperature deviates by 60 K indicating that the radiative time constant at 85 km altitude is of the order of 2 days. Perturbations of the mesospheric temperature, therefore, are very strongly damped and cannot persist for periods of longer than a few days unless they are continuously forced.

Intraplate earthquake swarms in Greenland and adjacent continental regions

Søren Gregersen

Geodaetisk Institut, Gamlehave Alle 22, DK-2920 Charlottenlund, Denmark

Earthquake swarms, consisting of many earthquakes of nearly equal magnitude within a small area, often occur in areas of recent or current volcanic or tectonic activity[1]. But earthquake swarms can also be recognised in some typical intraplate areas in northern Canada[2], Norway and Greenland. A swarm of earthquakes started in Meløy in November 1978, remarkable because no earthquake swarms in Norway[3] have been documented previously. The Meløy swarm occurred near the Norwegian coast, on one side of the Norwegian/Greenland Sea. A few earthquake swarms have occurred also in Greenland, near the east coast, by the Norwegian/Greenland Sea, and near the north coast, by the Arctic Ocean as have most of the swarms in northern Canada[2,4]. Some common features of the earthquake swarms in Greenland, Norway and northern Canada are indicated here.

The earthquake swarms in Greenland have occurred in areas with a tectonic setting and an earthquake activity similar to that of Norway. Figure 1 shows two time sequences of earthquakes within small areas. As none of the earthquakes is the main event in either sequence, the sequences are termed earthquake swarms. The largest earthquakes of the swarm in eastern Greenland had magnitude 2.7 according to the Nuttli scale[5]. The smallest earthquakes of the swarm, which can be identified as having occurred in the same source area, had magnitude 1.9. A simple linear relationship between the magnitude and the logarithm of the number of earthquakes in each magnitude range could not be determined reliably—no b-value could be found for the earthquake swarm. Altogether the energy release in the swarm corresponds to the energy release of one single earthquake of magnitude a little over 3 (a small event).

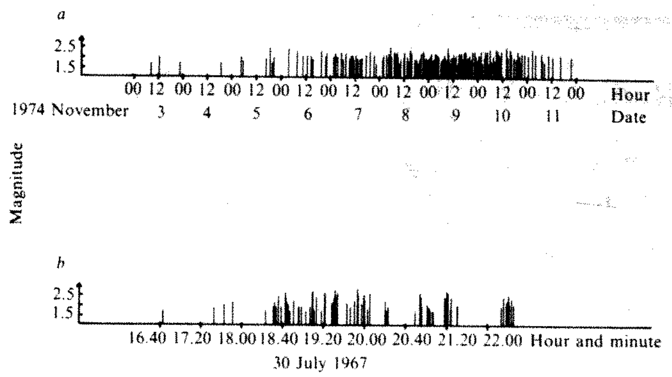

Fig. 1 Time sequences of the earthquake swarms in eastern (*a*) and northern (*b*) Greenland. Magnitudes are based only on readings from the seismological stations DAG and ALE respectively. No earthquakes occur at the swarm locations either immediately before or after the illustrated time intervals.

The earthquake swarm in northern Greenland lasted a shorter time than that in eastern Greenland. (The time scales of Fig. 1 *a* and *b* are different; 2 min for the sequence in northern Greenland correspond to 1 h for the sequence in eastern Greenland.)

The largest earthquake of the swarm in northern Greenland had magnitude 2.9 according to the Nuttli scale[5]. The smallest earthquakes, which can be clearly identified to have happened in the same source area, had magnitudes 1.8. The b-value for the earthquake swarm is around 1.0 with a large uncertainty, because the magnitude range is small. The energy release in the swarm corresponds to the energy release of a single earthquake of magnitude a little over 3, which is a small event and similar to that in eastern Greenland. In the swarm in eastern Greenland ~160 earthquakes have been distinguished, while in the swarm in northern Greenland 80 earthquakes have been found.

In eastern Greenland the earthquake swarm location around 73.5 ° N 20° W (Fig. 2) is based on seismograph records of the 25 largest earthquakes of the swarm from two seismological stations in Danmarkshavn (DAG) and in Kap Tobin (KTG). The uncertainty in the location of the swarm is 100 km in an east–west direction, while it is 25 km in a north–south direction. The earthquake swarm is in an area where neither single earthquakes nor earthquake sequences are known to have happened previously. The smaller earthquakes of the swarm have the same recorded signature at station Danmarkshavn (DAG) as the larger earthquakes, but they cannot be distinguished at the less sensitive station Kap Tobin (KTG). None of the earthquakes were recorded at other seismological stations.

The calculation of the location of the earthquake source area in northern Greenland 81.5° N 49° W (ref. 4) (Fig. 2) is based on records from the seismological stations Alert (ALE), Inge Lehmann (ILG) and Nord (NOR). Not all of the earthquakes could be distinguished at station Nord. Earthquake sequences have been observed at the station Alert several times before, as well as after, the sequence in Fig. 1, at similar distances, presumably near the same location. The ILG station operated for only 1 yr and only the abovementioned earthquake sequence occurred during that time. The earthquakes were not recorded at other seismological stations.

In northern Canada earthquake swarms are quite common[2]. All of the swarm locations there are plotted in Fig. 2. In Canada, Greenland and Norway the swarms are situated a long way from

0028-0836/79/430661—02$01.00

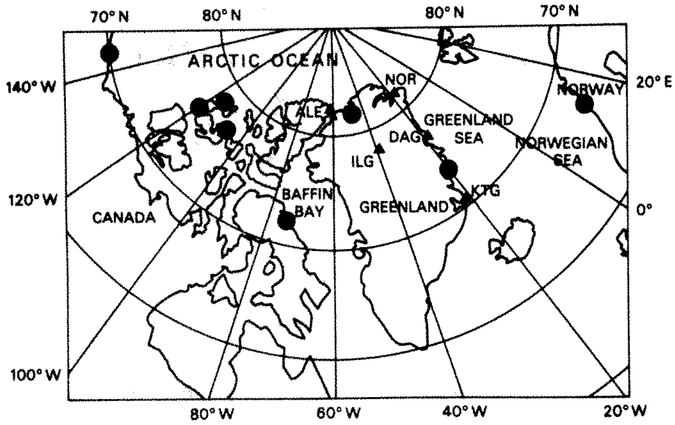

Fig. 2 Map with the recognised intraplate earthquake swarms (●). For the continental regions adjacent to Greenland the locations of the earthquake swarms are from published sources[2–4,6–10]. ▲, Seismological stations, mentioned in the text, with a three-letter code.

present plate boundaries. The swarms in Norway and in eastern Greenland are close to the passive continental margins of the Norwegian/Greenland Sea, in the middle of which an active mid-ocean ridge is located[11]. The swarms in northern Greenland and northern Canada[2,4] are located close to the passive margins of the Arctic Ocean and Baffin Bay. In the Arctic Ocean there is an active mid-ocean ridge[2]. In Baffin Bay there is no active mid-ocean ridge; the active spreading ceased >40 Myr ago[12]. In all of the swarm locations there are basins of sediments close to the continental margins[3,4,13,14]. The swarm activities are close to these sediment basins, whether these are of Palaeozoic ages as in northern Greenland or of Mesozoic ages as in eastern Greenland. These swarm locations are at the edges of continental areas which since the end of the last ice age (~10,000 yr ago) have been exposed to considerable uplift. The earthquakes in the swarms are found to be shallow in the cases where they could be determined[3,4,6] so the earthquake swarms presumably occur in the upper crust.

The swarms did not occur in the usual locations of earthquake swarm activity, which are areas of current or recent volcanic or tectonic activity[1]. They occurred far from interplate boundaries, so they may be classified as intraplate earthquake swarms. Sykes[15] noted that many intraplate earthquakes occur along old zones of weakness near continental margins and the same interpretation is reached from the present results. The earthquake swarms occurred along continental margins where the structures in and around the old sedimentary basins are the zones of weakness. The geological ages of the sedimentary basins are of little importance. The tectonic stresses which give rise to the intraplate earthquakes may be those connected with the present plate tectonics motion[15], but a special source of stresses in Greenland and the adjacent continental regions is the considerable uplift of these regions since the last ice age.

Radiocarbon chronology of late Pleistocene Konya lake, Turkey

Neil Roberts*, Oğuz Erol†, Titus de Meester‡ & Hans-Peter Uerpmann§

* Department of Geography, University College London, Gower Street, London WC1, UK

§ Institut für Urgeschichte, Universität Tübingen, Tübingen, FRG

The Konya basin in south central Turkey, which is now largely dry, was formerly occupied by an extensive lake[1,2]. Although the lake is generally considered to be of glacial age, its precise chronology has remained uncertain[3]. We report here preliminary ^{14}C dates on shells which suggest that lake level attained its last maximum 23,000–17,000 yr ago. We further propose that its subsequent retreat reflects a late glacial climate that was dry as well as cold.

The Konya plain is an area of internal drainage lying ~1,000 m above m.s.l. on the southern edge of the Anatolian plateau (Fig. 1). Rivers enter the basin from the Toros (Taurus) mountains to the south and west, and eventually discharge into small lakes at Ak gölü and Hotamıs and marshes at Aslım and Hamidiye. The rest of the plain is now dry. Shorelines of the former lake can easily be traced from eroded cliff-lines and depositional features such as beaches and spits, which do not seem to have been subsequently affected by folding or faulting. The lake covered ~4,340 km^2 at its last maximum, but the depth of water did not exceed 30 m and at most places was <15 m. The Konya lake was thus larger but much shallower than the contemporary Lisan Lake in the Jordan rift[4].

Most of the ^{14}C samples discussed here came from shell beds in sand and gravel deposits of shoreline features. The Main Series of dates were from samples taken at elevations between 1,004 and 1,012 m, and those in the Upper and Lower Series were on samples from higher and lower elevations respectively (Table 1). All dates were determined on shell, and in all but two cases the species involved was *Dreissena*, a small aragonitic bivalve which prefers fresh or brackish, open-water conditions[5]. The two exceptions, which date a minor lake transgression (Lower Series), were on *Lymnaea*, which was one element in a molluscan assemblage indicative of shallow, stagnant water[5,6].

Contamination by young carbon is the major problem in the ^{14}C dating of shells older than 10,000 yr (ref. 7). Several shells in the Konya samples were found to have a secondary coating of calcite which had formed by percolating meteoric water after the retreat of the lake. The distorting effect of this on radiocarbon age is seen clearly in a sample from Dervişin Hanı, where the inner and outer shell fractions gave ages of 17,610 ± 160 and 11,540 ± 120 yr BP respectively, the latter age having been depressed by the secondary calcite cement (Table 1). One of the Kılbasan samples (10.a.i.) was also found to contain up to 8% calcite, and its age of 14,660 ± 155 yr BP should therefore be considered as a minimum.

Other samples were analysed by X-ray diffraction and optical and scanning electron microscopy, and were hand-sorted to remove contaminated specimens before submission to the radiocarbon laboratory. This procedure allowed elimination of secondary calcite at levels above 1–2%. The resulting improvement can be seen in sample 2.a.i., also from Kılbasan, where the discrepancy between the ages of inner and outer shell fractions was greatly reduced. But because of these problems and of possible uptake of 'old' carbon, it is felt that a 10% margin of error should be applied to most of the ^{14}C dates listed here.

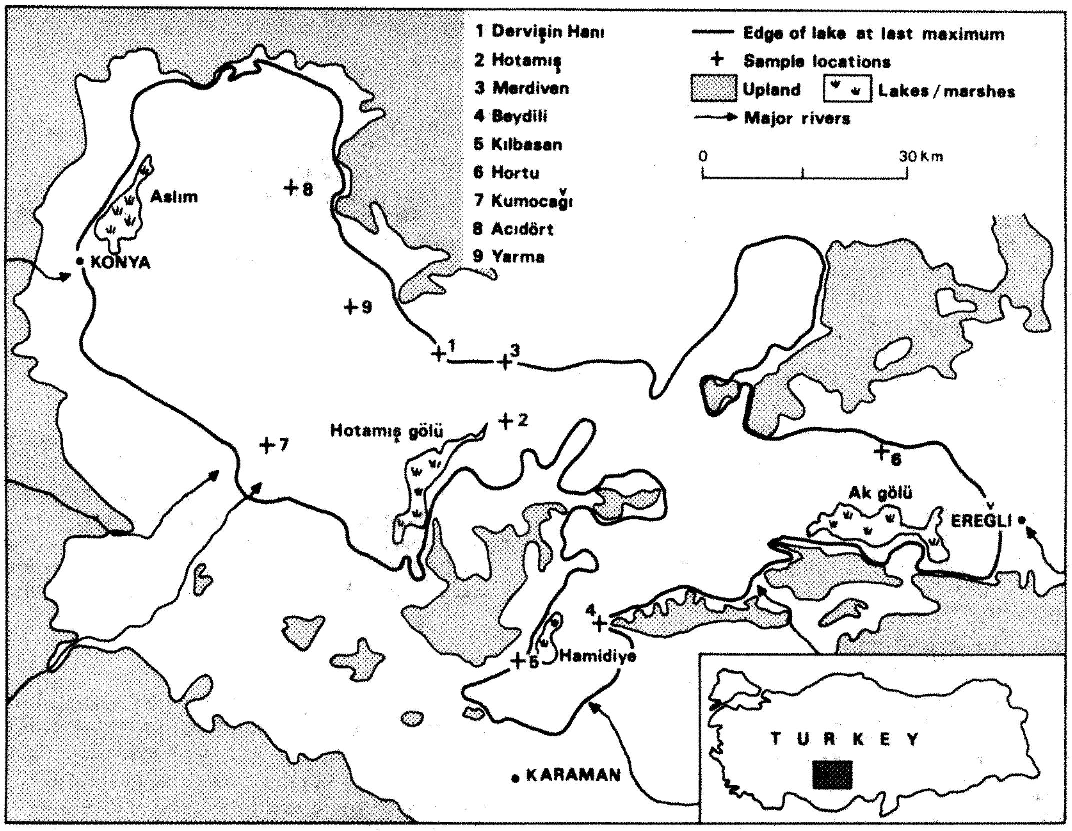

Fig. 1 Location of sample sites in Konya basin.

The radiocarbon dates are, nonetheless, consistent in suggesting that the last major phase of high lake levels in the Konya basin occurred between 23,000 and 17,000 yr BP. The lake had existed in the period immediately before this, but was at a low level. On the other hand, after 17,000 yr BP during the late glacial stage, the basin seems to have been largely dry. A minor re-advance in isolated secondary depressions between 12,000 and 11,000 yr BP may have been caused by glacial meltwater and by overflows from a higher lake system in the Beyşehir–Suğla basin. Archaeological mounds or hüyüks lie on the floor of the Konya basin and thus post-date the last lacustral interval. The oldest excavated hüyüks are Can Hasan III (with ^{14}C dates back to 8,600 yr BP)[8] and Çatal hüyük (dated between 8,200 and 7,500 yr BP)[9]. The fauna from Can Hasan III indicates generally dry, steppic conditions in the Karaman sub-basin around 8,500 yr BP (S. Payne, personal communication). The Konya basin has therefore been dry for most of the Holocene, although there is evidence for more extensive and permanent flooding in the Konya–Çumra area during the mid-Holocene[3].

The proposed late Pleistocene lake level sequence from Konya is in general agreement with those from other Middle Eastern basins, such as Lakes Lisan[4] and Mundafan[10], where the last high-stands occurred before $16\text{–}17 \times 10^3$ yr ago. It also differs markedly from the sequence in the south-west US, where many palaeo-lakes were at high levels between 17,000 and 10,000 yr BP (ref. 11). The early Holocene lacustral episode well

(Kılbasan	37°21′ N, 33°13′ E	UM 1577	14,660±155)	10.a.i. (minimum age)
Dervişin Hanı	37°45′ N, 33°05′ E	H 4181–3412	17,610±160	Ky 1b inner shell fraction
(Dervişin Hanı	37°45′ N, 33°05′ E	H 4181–3411	11,540±120)	Ky 1a outer shell fraction (minimum age)
Lower Series				
Yarma	37°48′ N, 32°58′ E	GrN 6016	12,010±65	
Acıdört	37°58′ N, 32°52′ E	GrN 5841	10,950±65	shells from dark organic marl

All dates were calculated using the 5,568 half life, and are normalised for ^{13}C fractionation to $\delta^{13}C = -25‰$ relative to PDB. Samples listed in brackets have suffered secondary contamination, and their ^{14}C ages are taken to be minima.

documented for much of Africa[12] and Arabia[10] is not recorded in the Konya basin.

The shallowness of the Konya lake and its disappearance during the post-glacial rise in temperature both point to the critical role of evaporation in the water balance of the lake. As there is no evidence of major temperature changes associated with the main lake retreat, one must conclude that this regression was a product of climatic aridity. A decline in precipitation during the late glacial is also indicated by very low levels of arboreal pollen in cores from Söğüt and the Ghab[13]. It thus seems that not only the tropics but also the extra-glacial mid-latitudes were subject to major variations in precipitation during the glacial Pleistocene. These variations seem, moreover, to have been out of phase with the global palaeotemperature changes indicated by deep-sea cores[14]. Work now in progress is intended to relate the Konya sedimentary sequence to palynological and archaeological data, and to elucidate the palaeohydrology of the basin.

The cost of some of the dates was met by the Central Research Fund, London University. We thank Claudio Vita-Finzi for assistance with shell analyses and for helpful criticisms.

Chlorophyll and nitrate fine structure in the southeastern Bering Sea shelf break front

R. L. Iverson*, T. E. Whitledge† & J. J. Goering‡

* Department of Oceanography, Florida State University, Tallahassee, Florida 32306
† Division of Oceanographic Science, Brookhaven National Laboratory, Upton, New York 11973
‡ Institute of Marine Science, University of Alaska, Fairbanks, Alaska

Ocean fronts of considerable spatial extent and temporal persistence have been described for the shelf break region along the North American Atlantic coast[1–3] and along the eastern Bering Sea shelf[4]. Intensive fishing activity in the vicinity of the shelf break front along the mid and north Atlantic coast suggests that high biological activity is associated with the front[5,6]. Primary productivity and chlorophyll standing crop are enhanced along the Scotian shelf break front as a consequence of vertical transport of nutrients to the photic zone[7,8]. Although physical data suggest that shelf break fronts persist for periods of from weeks to years, space and time scales associated with biological activity in shelf break fronts are not well known. We report here the spatial scales and fine structure of chlorophyll and nitrate distribution in near-surface waters of the shelf break front in the southeastern Bering Sea. Data collected on several cruises during an investigation of the processes and resources of the Bering Sea shelf (PROBES) allow a first order estimate of the time scales of persistence of nutrient and phytoplankton dynamics associated with the shelf break front. Properties associated with an extensive middle shelf front inshore of the shelf break front are reported elsewhere[9].

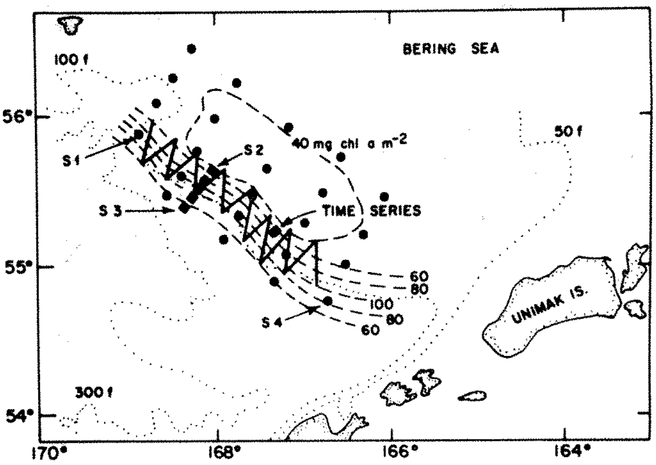

Fig. 1 PROBES study area in the southeastern Bering Sea. Contours of vertically integrated chlorophyll (mg m^{-2}) were prepared from data taken at hydrocast stations (●). The mapping track is indicated by the solid lines. The time series station location lies near the arrowhead. SI is station 3002, S2 is station 116, S3 is station 120, and S4 is station 3038.

CTD data taken at hydrocast stations (Fig. 1) were processed with a digital computer aboard the RV Thomas G. Thompson. The shelf break front was evident near station 120 in both density and salinity data (Fig. 2). The shelf break front is characterised by a salinity gradient which extends about 1,000 km along the continental shelf of the eastern Bering Sea[4].

Chlorophyll values were obtained by *in vivo* fluorometric measurement of phytoplankton pigments in water obtained from the sea chest of the RV Thomas G. Thompson ($z = 3$ m). Continuous *in vivo* chlorophyll values measured with a fluorometer (Turner Designs) were calibrated against extracted fluorescence chlorophyll values for water samples taken every 30 min from the exhaust side of the fluorometer ($r^2 = 0.91$). Nutrient concentrations were measured continuously with an Autoanalyzer for water samples taken from the sea chest line[10]. One-minute interval samples were taken from the detectors

Fig. 3 *a*, Map of chlorophyll concentration ($\mu g\ l^{-1}$) at 3 m depth on 26 May 1978. The time series station was located at the triangle. *b*, Map of nitrate concentration (μg atoms of NO_3 per l of N) and 3 m depth on 26 May 1978.

over a 36-h mapping track (Fig. 1). Five-minute averages of the samples were contoured on board ship with a digital computer to produce maps of chlorophyll and nutrient concentrations. Nutrient and chlorophyll concentrations were measured for water samples taken from Niskin bottles tripped at various depths at selected stations. Uptake velocities of nitrate and ammonium were determined for phytoplankton communities using a ^{15}N isotope tracer technique[11]. Samples were taken periodically for microscopic examination of phytoplankton.

Vertically integrated chlorophyll values obtained from extracted fluorescence measurements for discrete water samples obtained from hydrocasts were contoured with a digital computer program. Chlorophyll was distributed along the shelf break in a band about 30 km wide with a maximum in the region of the 100 fathom isobath; integrated chlorophyll values decreased by about half on either side of the frontal maximum (Fig. 1). The front moves with the tide, with an estimated maximum speed[12] of 50 cm s^{-1}, which explains the difference in location of the front in the physical data (Fig. 2) and the location of the chlorophyll maximum obtained by contouring data taken at various stages of the tide.

A surface mapping track was designed to bracket the 100 fathom isobath from the Aleutian Island chain north to the Pribilof Islands. A fine structure map prepared from data collected on this track suggests the chlorophyll maximum was ~15 km wide with chlorophyll values generally larger towards the Pribilof Islands (Fig. 3*a*). The map track covered a horizontal distance of about 170 km along the shelf break. Although the gradients across the front were evident in the chlorophyll field along the complete length of the map, structure in the near-surface chlorophyll field was most distinct from background chlorophyll in the northern 100 km. Structure in the nitrate field was not as detailed as structure in the chlorophyll field; however, local minima in nitrate concentration generally coincided with local maxima in chlorophyll concentration (Fig. 3*b*). A subsurface chlorophyll maximum present in the southern portion of the transect (Fig. 4) was not observed in the mapping data set because of the 3-m sampling depth. Silicate and phosphate concentrations did not exhibit the structure observed in the near-surface nitrate map but the general trends were similar with higher values to the north and lower values near the Aleutian Island chain.

A time series station was occupied within the shelf break chlorophyll maximum region in early May before mapping the front in late May. The vertical distribution of chlorophyll and nitrate show frontal excursion past the fixed station (Fig. 5). Surface water displacement produced a large gradient both in chlorophyll and in nitrate concentrations near the surface; however, nitrate concentrations remained relatively constant below about 40 m. The photic zone depth (depth where light intensity is 1% of the surface value) was 40 m at station 2010 outside the chlorophyll maximum region, 14 m at station 2016,

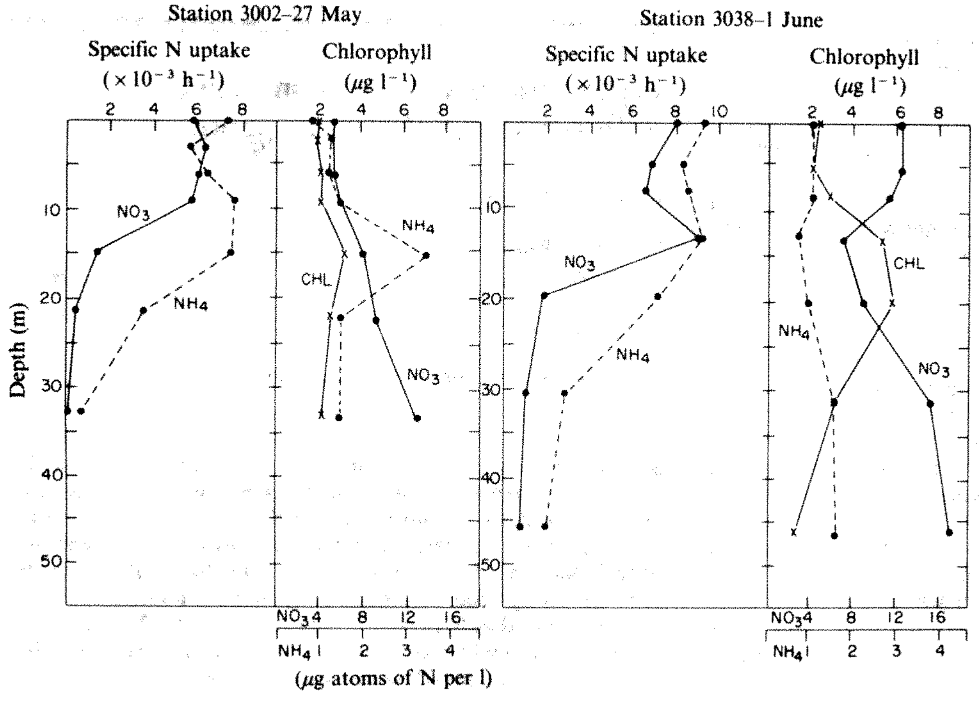

Fig. 4 Nitrate, ammonium, and chlorophyll concentrations measured from hydrocast water samples. Specific nitrogen uptake velocities for phytoplankton from the hydrocast samples held 24 hours in a deck incubator at the light intensity at the depth where they were collected.

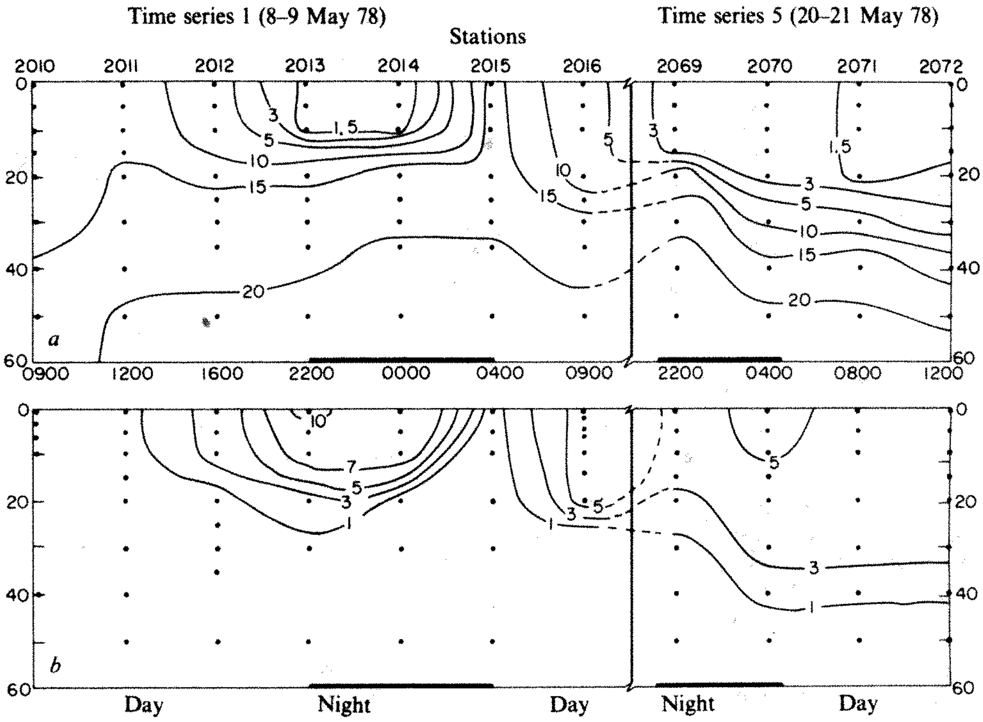

Fig. 5 *a*, Nitrate concentration (μg atoms of NO_3 per 1 of N) and *b*, chlorophyll concentration (μg chl per 1) measured at the time series station.

and 16 m at station 2071 near the chlorophyll maximum. Productivity below 20 m at station 2071 was zero for ^{14}C estimates. An indication of the persistence of chlorophyll and nitrate patterns in the front with time can be seen in the continuation of the patterns in chlorophyll and nitrate concentrations with depth at the same station two weeks later. The station was located with Loran C, considered accurate to within 200 m in the southeastern Bering Sea. A significant portion of the water column chlorophyll had settled to the base of the photic zone by the end of the second phase of the time series, although vertically integrated chlorophyll values were similar at stations 2013 and 2071. Silicate was nearly constant between 28 and 30 μg atoms of Si per 1 in the photic zone during the time series, supporting a contention that diatoms were not a major constituent of the phytoplankton in the shelf break front.

Nitrogen uptake velocities obtained with ^{15}N nitrate and ammonium allow estimation of nitrogen doubling times for phytoplankton communities. A doubling time of about 4 days was calculated for *Pheocystis poucheti* which numerically dominated the phytoplankton at station 3002 (Fig. 4). The ammonium maximum at 15 m was coincident with a shift in phytoplankton species composition to a community co-dominated by *Biddulphia* sp. and *Prorocentrum* sp. which doubled in about 3.5 days. A doubling time of about 5 days was calculated for the surface sample at station 3038 where *Cylindropyxis tremulens* and *Thalassiosira aestivalis* dominated the phytoplankton. Nitrogen doubling times were similar up to 15 m, below which doubling times ranged from 16 to 30 days. Nitrogen uptake was observed at the 0.1% light depth; however, carbon fixation was usually not different from zero at the 1% light depth. There was a transition from *Pheocystis poucheti* which formed blooms near the surface to a phytoplankton community dominated by diatoms and dinoflagellates as the photic zone deepened with the sinking of the chlorophyll maximum layer in the shelf break front.

The pattern exhibited by chlorophyll and nitrate maps and in hydrocast data suggests that the phytoplankton bloom in the shelf break front of the southeastern Bering Sea was constrained to a narrow ribbon parallel to the 100 fathom isobath. A chlorophyll maximum was always observed along the 170 km length of the front but the maximum was not always at the surface. The chlorophyll maximum persisted in the shelf break front through September 1978 and was observed again during spring 1979.

This research was sponsored by the NSF under grant DPP7623340. We thank Sue Banahan for processing the ^{15}N samples.

Hypersaline solutions interact with organic detritus to produce oil

Egon T. Degens

Geologisch-Paläontologisches Institut, Universität Hamburg, Hamburg, FRG

Antonin Paluska

Geologisches Landesamt Hamburg, Hamburg, FRG

Salt is a major factor in the origin of petroleum. It leads to the extraction of hydrocarbons from sediments and the formation of oil droplets. Also, salt domes and their cap rocks may trap oil[1]. Although the diagenesis of salt and brines is well understood, little is known what salty brines may do to infalling organic detritus. Using results from the Caspian Sea and the North Sea we show here that hypersaline solutions close to the sediment-water interface will cure organic matter and that this 'pickling effect' is essential for obtaining black and oil shales.

0028–0836/79/430666—03$01.00

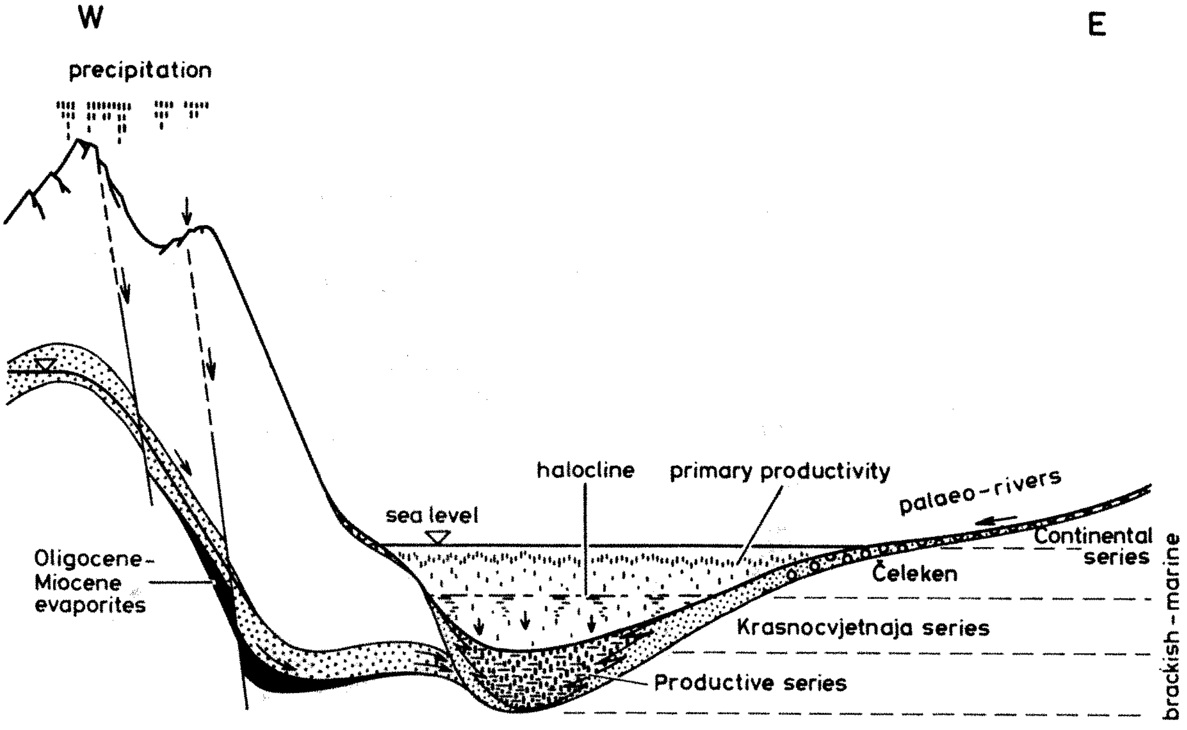

Fig. 1 South-Caspian depression during Kimmer/Akchagyl time; evaporite series are shown in black.

The Black Sea is considered the prototype environment for the black shale facies[2]. During the RV Glomar Challenger DSDP Leg 42B a series of black shales, oil shales and sapropels of Quaternary age were recovered from the Black Sea deep basin at a water depth of about 2,000 m (ref. 3). The 'euxinic events' responsible for this facies pattern are all characterised by saline spills or brine invasions, which in turn led to a midwater halocline and a meromictic basin. Note that oil shale facies develops in a shallow water environment at a water depth of at most a few hundred metres[4]; hypersaline conditions with salinities reaching 100‰ are indicated[5]. In contrast, sapropels are confined to a deep water meromictic sea and salty brines covering the topmost sediment are of lower salinity[4]. Oil shales have ages between 1 and 2 Myr, an organic C content between 0.5 and 2%, and downhole temperature measurements indicate a thermal gradient between 30 and 50 °C per km (ref. 6). These results suggest that hydrocarbon formation in the Black Sea was fast, proceeded at low temperature, and was mediated by syngenetic salt invasions.

In the light of these data we examined two test regions, the Caspian Sea and the North Sea, where we believe similar environmental conditions did prevail except that the geological processes have already led to the accumulation of sizeable oil deposits[7].

During the Pontic marine phase (lower Pliocene) wide parts of Russia and southeastern Europe were covered by a land-locked shallow sea[8]. The subsequent Kimmer regression reduced the sea to a few isolated basins located in the region of the present south-Caspian depression[9]. The Kimmer climate was arid and the palaeo-rivers Volga, Amudarja and others carried a high salt load to a comparatively small Caspian drainage basin. Pliocene orogeny, still active during the Kimmer, led to the formation of mountains in the vicinity of the Caspian Sea[10]. Groundwater under high pressure within the tilted rock formation moved towards the south-Caspian depression where it was released in the form of Artesian wells. Since the aquifer drained evaporites of Oligocene–Miocene age, mineralisation of the groundwater must have been substantial.

The geological and environmental situation around Kimmer and Akchagyl time is depicted in Fig. 1. Bleeding of groundwater aquifers below sea level combined with brine migration from lagoons resulted in the accumulation of salty brine pools in morphological deeps; a midwater halocline separated the brines from normal Caspian Sea water. The Akchagyl transgression following the Kimmer regression produced a facies succession from clays to sands to gravel (Productive, Krasnocvjetn Čeleken, Continental series); brackish-marine and continental deposits mark this event[11]. High primary productivity is indicated, and consequently the Productive series below the halocline received a high input of organic matter and the anoxic conditions established preserved the infalling organic detritus. As the Akchagyl transgression took place at about the Tertiary/Quaternary boundary, generation of hydrocarbons and formation of oil traps must have been quite rapid.

Our second test case, the North Sea, follows an almost identical pattern, except that the black shale event was much earlier, during the Upper Jurassic[12]. A schematic cross-section along a line from Norway to Scotland at the time of the formation of the Kimmeridge clay (Malm) depicts the functionality of the Zechstein and Keuper evaporite series for the generation of a salty groundwater aquifer (Fig. 2). Such a mineralisation and the subsequent release to the basin of deposition was possible at Kimmeridge time because the potential needed for the Artesian pressure was generated at that time by tectonic uplift in Scandinavia and tectonic subsidence in the vicinity of the Central Graben. The water depth in the Central Graben during the Upper Jurassic has been estimated to be at about 1,000 m and a few hundred metres close to the shelf area[13]. In short, the generation of oil shale facies required euxinic conditions and a hypersaline syngenetic environment close to the sediment–water interface. Note that the generation of hydrocarbons could already have started during the Kimmeridgian tectonic phase. The presence of North Sea oil in younger rock formations, for instance, of the early Tertiary, may be linked with hypersaline anoxic events in the Eocene and Oligocene. Alternatively, a

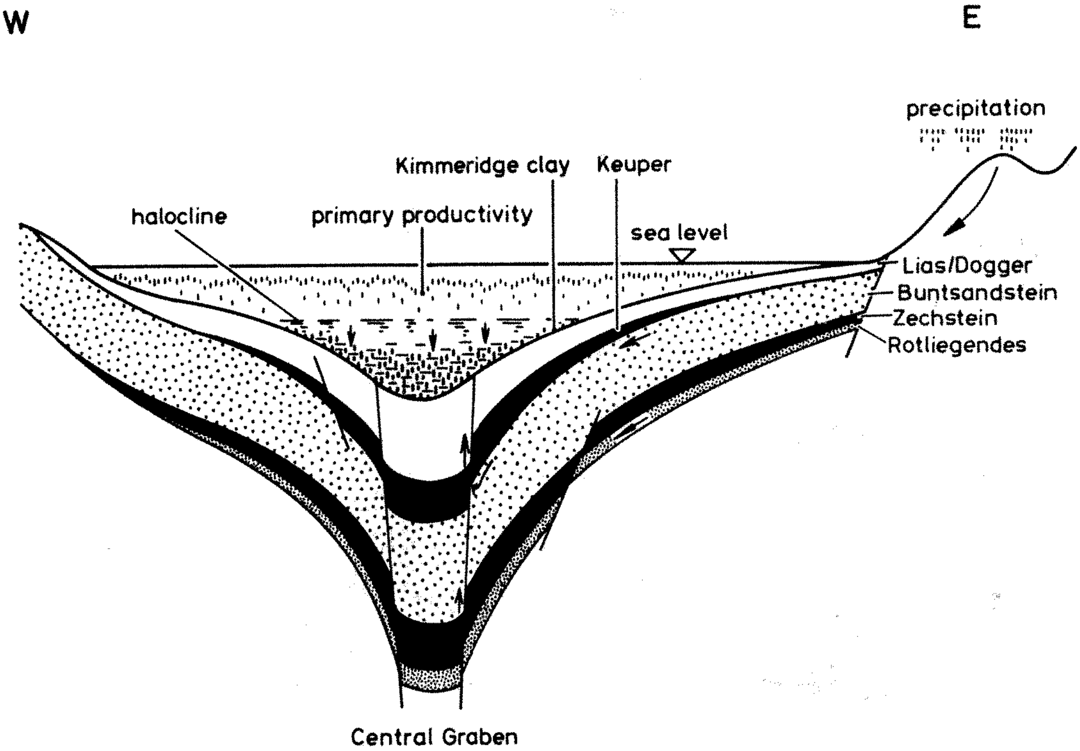

Fig. 2 North Sea at Kimmeridge time; evaporite series are shown in black.

migration of Jurassic petroleum into younger reservoir rocks is conceivable.

Salt water driven by Artesian forces is presently expelled from Red Sea sediments and accumulates in the so-called 'hot brine pools' (ref. 14). The brines are released in pulses which are in phase with pluvial incidents. An identical situation exists in some deep lakes of the East African rift system, most notably in Lake Kivu[15]. In both areas the brines extend from the sea or lake floor up to 200 m into the open water column and are separated from the upper water layer by one or a series of haloclines. Such a decoupling of the upper from the lower water layer will generate anoxic conditions at depth.

Salt invasions will drastically affect marine life in sediment and water. Higher forms of aquatic life become wiped out completely, and microbial population patterns undergo distinct changes in response to, for example, the degree of salinity, ionic composition or brine temperature[16]. Some of these changes are limiting, others are accelerating factors for microbial productivity. High general salinity combined with high calcium content might even act bacteriostatically on sulphate-reducing bacteria[17]. In contrast, halophilic bacteria may thrive in salty waters[18]. The establishment of characteristic microbial food chains or food webs adapted to the new environmental conditions can lead to a transformation of low molecular weight carbon compounds such as CO, CO_2, CH_4, organic acids into bacterial biomass[18]. The microbial complexity of brine systems is well documented in the work on Red Sea brine pools[17], Lake Kivu[15] or the Black Sea[19].

With respect to oil shale formation the most favourable environment seems to be one in which decomposition of high molecular weight organic matter is kept low and synthesis of bacterial biomass from low molecular weight carbon compounds is high. In such conditions, infalling organic debris of marine and terrestrial origin has a good chance of 'surviving' early diagenesis. This, combined with additional increments from microbiological organic matter, yields the high molecular weight precursor material for the generation of oil.

The formation of oil shales requires high primary productivity, hypersaline conditions at depth, and a gradually subsiding basin. Microorganisms such as methane producers, methane oxidisers (close to the halocline), halophilic bacteria or thermophilic bacteria will supplement the organic input into the sediment. The activity of organisms consuming organic matter, such as sulphate reducers, must be low. The salty waters will sink into the sediment and impregnate the rock formation. Most of the salt in petroleum brine waters has this point of origin. Curing by salt will preserve and condense organic matter. For this reason kerogen in oil shale is of a different nature from kerogen in an ordinary marine or freshwater shale. In taking these environmental and geological factors into consideration, oil exploration may take on some new dimensions.

We thank Shell Grants Committee London for financial support.

Oldest known eutherian stapes and a marsupial petrosal bone from the Late Cretaceous of North America

J. David Archibald

Department of Biology and Peabody Museum of Natural History, Yale University, New Haven, Connecticut 06520

Cranial remains of Late Cretaceous therian mammals are rarely found in North America and are usually limited to isolated petrosal bones. The oldest known associated stapes and petrosal bone of a Late Cretaceous eutherian are reported here. Comparison with a Late Cretaceous marsupial petrosal bone gives a further indication of the probable condition of several character states of the ancestral mammalian (or at least therian) middle ear, and also indicates the antiquity of various aspects of the middle ear of extant eutherians and marsupials.

A worn and isolated eutherian petrosal, lacking most of the mastoid process, was identified in the collections of the US National Museum of Natural History. The specimen, USNM 215118 (Fig. 1*a*, *e*), comes from the Late Cretaceous Bug Creek Anthills local fauna (Hell Creek Formation, McCone County, Montana)[1]. MacIntyre[2] described several well preserved eutherian petrosals from this local fauna which he called 'ferungulate' and 'unguiculate' types. The former probably belongs to the arctocyonid condylarth, *Protungulatum donnae*, and the latter to the palaeoryctid proteutherian, *Procerberus formicarum*. USNM 215118 is of the latter type and is unique in preserving a broken but complete stapes wedged in the cochlear labyrinth (Fig. 1*a*, *b*). The other petrosal described here also comes from the Hell Creek Formation, but about 60 km to the west, in Garfield County, Montana. This well preserved specimen, UCMP 118262, is almost certainly a marsupial, based on its provenience and morphology. It is slightly smaller than the only other known Late Cretaceous marsupial petrosal, that of the stagodontid, *Didelphodon vorax*[3]. Based on size, UCMP 118262 probably belongs either to one of the pediomyids, *Pediomys hatcheri* or *P. florencae*, or to the didelphid, *Alphadon rhaister*.

The stapes associated with the eutherian petrosal has an elongate footplate. The crura are quite gracile and set near either end of the footplate, and the stapedial foramen is large. The stapedial muscle probably inserted on the capitulum or on the thickened portion of the posterior crus immediately below (medial to) the capitulum (is, Fig. 1*b*). This stapedial morphology is seen in various extant eutherians[4]. Although the Late Cretaceous marsupial petrosal has no stapes, the shape of the footplate can be estimated from the shape of the fenestra vestibuli (fv, Fig. 1*f*), as can be done for the Late Cretaceous eutherian petrosal (fv, Fig. 1*a*) because in mammals the fenestra vestibuli outlines the shape of the adjacent stapedial footplate.

Segall[5] quantified the shape of the footplate or fenestra vestibuli as the ratio of length to width. Among didelphid marsupials he found ratios of 1.3–1.5, with the exception of *Dromiciops* at about 2.1. *Dromiciops* has a highly modified ear region and is not considered to be a didelphid by some authors[6]. The fenestra vestubuli of UCMP 118262 has a ratio of about 1.4, the same as for *Didelphodon*. This value lies within the range measured for modern didelphids. In contrast, the eutherians (mostly lipotyphlans) examined by Segall have ratios ranging from 1.8 to 2.9. The ratio in the new eutherian petrosal, USNM 215118, is 2.4 based on the stapedial footplate and 2.1 based on the slightly damaged fenestra vestibuli. The figures of the 'ferungulate' eutherian petrosal of MacIntyre[2] also indicate a ratio of 2.0 or more based on the fenestra vestibuli.

Primitvely, mammals (and advanced mammal-like reptiles[7]) had a circular or possibly slightly oval stapedial footplate (equal to a ratio of about 1.0). Thus, the elongate footplates of the new Late Cretaceous eutherian, many extant eutherians and some extant marsupials (such as *Macropus*[5]) represent a derived condition. The smaller ratio in extant didelphid marsupials and in the new Late Cretaceous marsupial petrosal indicates a less elongate stapedial footplate, resembling more closely the circular footplate primitive for mammals.

There is less agreement about the primitive mammalian condition of the crura of the stapes. In monotremes and some marsupials with a circular or slightly oval footplate, the stapes is

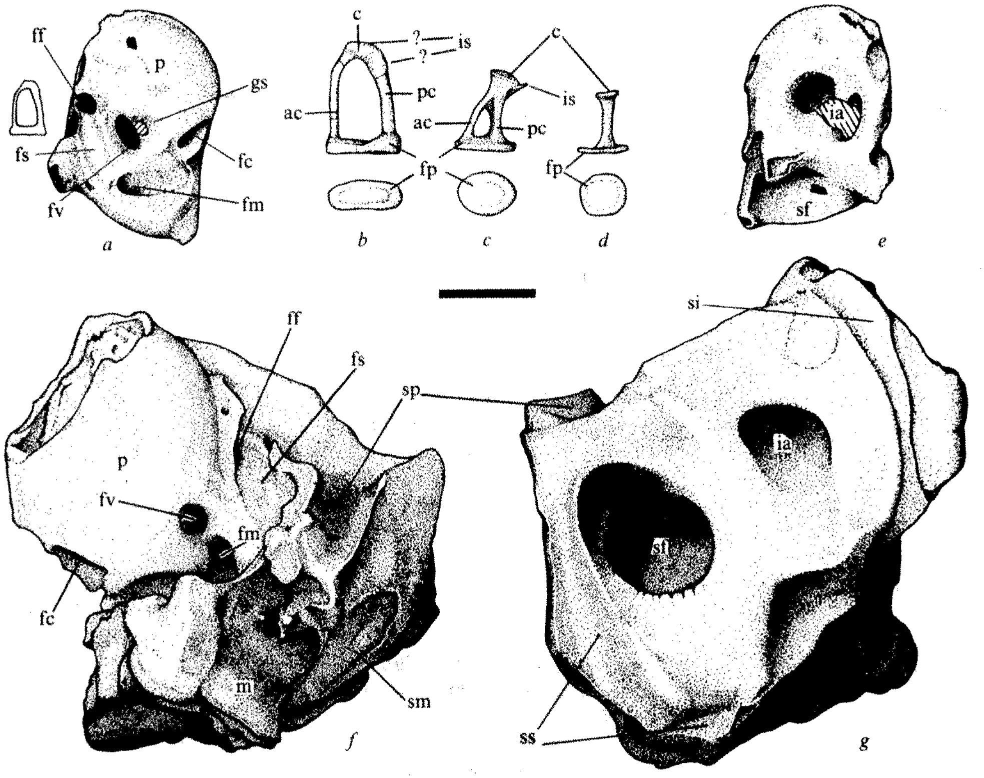

Fig. 1 Right petrosal (*a*, *e*) and stapes (*a*, *b*) of 'unguiculate' eutherian, USNM 215118, and left petrosal (*f*, *g*) of marsupial, UCMP 118262, both from Hell Creek Formation, Montana; right stapes of *Didelphis virginiana* (*c*) and *Tachyglossus aculeatus* (*d*); *a*, *f*, ventrolateral view, anterior approximately towards top; *b*, *c*, *d*, dorsal and medial views, anterior to left; *e*, *g*, dorsomedial view, anterior approximately towards top. ac, anterior crus; c, capitulum; fc, fenestra cochleae; ff, foramen for facial nerve; fm, fossa for origin of stapedius muscle; fp, footplate; fs, sulcus for facial nerve (broken bony canal in marsupial); fv, fenestra vestibuli; gs, groove for stapedial artery; ia, internal acoustic meatus; is, insertion for stapedius muscle; m, mastoid portion of petrosal; p, promontorium of petrosal; pc, posterior crus; sf, subarcuate fossa (broken in eutherian); si, sulcus for inferior petrosal sinus; sm, sulcus for vein leading to mastoid foramen; sp,? sulcus for portion of transverse sinus leading to postglenoid foramen; ss, posterodorsal portion of sulcus for sigmoid sinus. Scale bar, 2 mm (*a*, *d*, *e*, *f*, *g*) and 1 mm (*b*, *c*).

0028-0836/79/430669—02$01.00

columelliform and lacks a stapedial foramen. Segall[5] believes that this is the primitive mammalian condition. Henson[8] follows Goodrich[9] in believing that it is a derived condition.

In addition to many extant mammals, some extant lizards, birds and amphibians[8,9] have a perforate stapes (possess a foramen) that transmits the stapedial artery. In some mammal-like reptiles such as *Thrinaxodon*[7] the stapes had a large stapedial foramen. Whether a stapedial artery traversed this foramen is not known, but it seems likely. The perforate stapes of most mammals and various other fossil and extant tetrapods suggests that this was the primitive mammalian, if not primitive tetrapod condition. Thus, the primitive condition of the crura of the stapes among mammals would resemble the morphology of *Didelphis* (Fig. 1*c*) more closely than that of a monotreme (Fig. 1*d*). Both the columelliform crus of the monotreme stapes and probably the stirrup-like crura of the Late Cretaceous eutherian stapes (Fig. 1*b*) would be derived conditions.

The two new petrosals show several grooves for parts of the arterial and venous systems. Such grooves indicate the patterns of these systems in later fossil and extant eutherians and marsupials. Due to wear, the Late Cretaceous eutherian petrosal has only the shallow, but distinct groove for the stapedial artery (gs, Fig. 1*a*). Based on better specimens of the same type of petrosal[2], it almost certainly also had grooves for the medial internal carotid and promontory arteries. In contrast, the well preserved Late Cretaceous marsupial petrosal shows no trace of grooves for any of these arteries.

Both patterns are consistent with what is known of the evolution of the internal carotid circulation in eutherians and marsupials. The common ancestor of eutherians and marsupials had a medial internal carotid that passed medial to the petrosal, leaving little or no trace on this bone, and a stapedial artery that pierced the stapes, possibly leaving some trace on the petrosal[10]. Various lines of evidence suggest that the earliest eutherians maintained this general pattern, adding a neomorphic vessel, the promontory artery, which crossed the lateral side of the promontorium[10]. However, embryological evidence[11] suggests that the eutherian promontory artery represents a shift of the medial internal carotid to the promontorium.

In contrast, the evidence from extant marsupials indicates they neither developed a promontory artery nor shifted an artery to this position[10]. In addition, reports of a branch of the internal carotid passing through a groove or bony canal on the medial side of the marsupial petrosal[12,13] have not been substantiated[14]. Thus, such a groove in the Late Cretaceous marsupial petrosal (si, Fig. 1*g*) carried a portion of the venous system, the inferior petrosal sinus, not a branch of the internal carotid. Extant marsupials that have been studied usually have the medial internal carotid, while the stapedial artery is reduced[15]; seldom does either leave a trace on the petrosal. *Didelphodon* and the new Late Cretaceous marsupial petrosal similarly lack grooves for the medial internal carotid and stapedial arteries. By analogy, if not homology, both Late Cretaceous marsupials probably had a medial internal carotid, but lacked or had a greatly reduced stapedial artery.

These comparisons indicate the antiquity of several characters of the middle ear seen in various extant eutherians and marsupials. By the Late Cretaceous the stapes had been modified in at least some eutherians. Functional implications remain speculative. At the simplest mechanical level, the torque about the long axis of an elongate stapedial footplate such as in the Late Cretaceous stapes is less than about the axis of a circular footplate of the same area. Thus, even such a minor modification as the lengthening of the footplate may have enhanced the hearing capabilities of this eutherian. The much less elongate footplate (indicated by the shape of the fenestra vestibuli) of Late Cretaceous marsupials is a retention of a more primitive condition that is maintained in extant didelphids. The elongate footplate in various other extant marsupials evolved in parallel with the eutherians.

In contrast to stapedial morphology, the portions of the internal carotid system that cross the middle ear show a pattern of mosaic evolution in Late Cretaceous eutherians and marsupials. The common ancestor of mammals almost certainly possessed a medial internal carotid and a stapedial artery. By the Late Cretaceous, marsupials had greatly reduced or lost the latter vessel, whereas contemporaneous eutherians maintained it. Also, if the interpretations of the various grooves are correct, eutherians had developed a neomorphic vessel, the promontory artery, by the Late Cretaceous. Again, functional implications are speculative, but these various patterns may simply reflect a shifting of the arterial blood supply to portions of the brain and orbit; or in the case of eutherians, the probable appearance of a new artery may have served as a sort of primitive rete mirabile for cooling blood destined for the brain.

I thank G. MacIntyre for data, W. A. Clemens and K. Padian for comments, the staff of the cited museums for permission to study specimens, and L. Van Valen and R. Sloan for permission to describe a specimen from Bug Creek Anthills. Parts of this work were supported by NSF Grant DEB 77-24610 to W.A.C. This project was completed while I was a Gibbs Instructor in the Department of Geology and Geophysics, Yale University.

Effective mutualism between sequentially flowering plant species

Nickolas M. Waser

Department of Biology, University of California, Riverside, California 92521

Leslie A. Real

Department of Zoology, North Carolina State University, Raleigh, North Carolina 27650

Since the theoretical paper of Levin and Anderson[1], it has been widely recognised that animal pollinators represent resources for which plants can compete. Competition for pollination might take several forms and act as a powerful selective force in establishing or maintaining sequential flowering among sympatric species[2]. Sequential flowering in Arctic[3], temperate[4–9] and neotropical[10–13] plant assemblages has been interpreted as an evolutionary result of competition for pollination. This interpretation may prove correct in many cases, although strong evidence for competition is available for few systems[9,14]. Heinrich and Raven[15] (see also Baker[16] and Baker *et al.*[17]) pointed out that sympatric plant species may act as mutualistic partners at the same time that their sequential flowering is maintained by competition. We develop this hypothesis here explicitly and present evidence that effective mutualism occurs between two species which also compete for pollination.

To illustrate the hypothesis of mutualism we consider three sequentially flowering species which share pollinators (Fig. 1). If

Table 1 Densities of flowers, seed sets and census counts of hummingbirds from the RMBL

Year	Peak density of *D. nelsonii* flowers*	Peak density of *I. aggregata* flowers*	*I. aggregata* seed set†	Overall broad-tail census count‡	Late broad-tail census count§	Overall rufous census count‖
1975	25.0±9.20 (6)	29.3±13.26 (6)	10.1±0.73 (37)	10.2±1.44 (14)	8.6±2.09 (7)	7.1±2.79 (8)

* Values are mean number of flowers per 4 m^2 plot ±1 s.e.m. with sample sizes (no. of plots) in parentheses. Both species were counted every 2–3 days in 6 permanent census plots. The 1977 *D. nelsonii* value is a slight underestimate as the first census was taken when density of this species was already declining.

† Values are mean seed sets per flower ±1 s.e.m., with sample sizes (no. of flowers) in parentheses. Flowers were taken from unmanipulated plants in the meadow containing flower census plots.

‡ Values are mean number of flights by male broad-tailed hummingbirds per 10 min census ±1 s.e.m., with sample sizes (no. of censuses) in parentheses. Flights were censused at a standard time of day in the meadow containing flower census plots; no censuses were conducted in 1976. Censuses cover the flowering season of both species in 1975 and 1977 and flowering of *I. aggregata* alone in 1978.

§ Values are given as before. Only censuses conducted during flowering of *I. aggregata* have been included for each year.

‖ Values are given as before, except for male rufous rather than broad-tailed hummingbirds. Censuses cover the flowering season of *I. aggregata* only, as rufous hummingbirds were not present during flowering of *D. nelsonii*.

the time between peaks of flowering of species 1 and 3 is sufficient for the absence of species 2 to cause appreciable mortality, emigration, or loss of fecundity to pollinators, then species 2 increases immediate reproductive potential of species 3 by maintaining pollinators through some time interval t. When the flowering season (the period $T_1 \rightarrow T_2$) covers an entire year all three species are engaged in mutualism. When $T_1 \rightarrow T_2$ represents part of a year, a similar interaction occurs if colonisation, survival, or fecundity of pollinators depend on overall abundance of flowers or on their continuous availability throughout some critical period.

For this mutualism to occur numbers of pollinators must be reduced locally in response to reduced numbers of flowers. This seems especially likely for obligate flower visitors such as bees, bombyllid and syrphid flies, hawkmoths and most butterflies[18–20]. For example, survival and reproduction of bumblebee colonies seem to reflect availability of flowers[21]. Pollinators which are not obligate flower visitors also may react strongly to reduced flowering. For example, densities of territorial hummingbirds and sunbirds reflect densities of flowers[22–25] and poor flowering is associated with reduced survival and nesting success of hummingbirds[25–27].

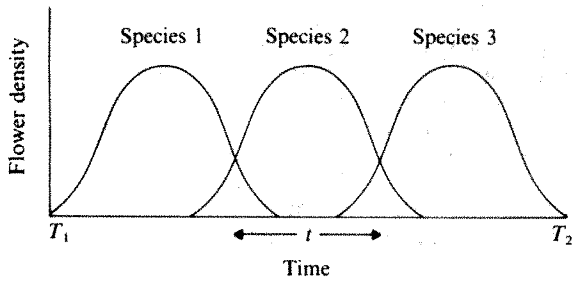

Fig. 1 Idealised sequential flowering of three sympatric species sharing common pollinators. Removal of any species leaves a period t during which few or no flowers are available locally.

Our previous work[9] suggests that competition for hummingbird pollination maintains sequential flowering of two herbaceous wildflowers, *Delphinium nelsonii* Greene and *Ipomopsis aggregata* (Pursh) V. Grant, around the Rocky Mountain Biological Laboratory (RMBL) in Colorado. From measurements of seed sets and densities of flowers over four summers we have evidence that these two species are also engaged in a mutualism of the kind we describe. Peak densities of *D. nelsonii* flowers were similar in 1975 and 1976 but declined drastically in 1977 and 1978 (Fig. 2, Table 1), presumably due to the 1977 winter drought. Densities of *I. aggregata* flowers remained relatively constant between years and were uncorrelated with densities of *D. nelsonii* flowers (Table 2*a*). The mutalism hypothesis predicts that reproductive success of *I. aggregata* will decline in the 2 years of low density of *D. nelsonii*. This prediction is supported by reduced seed sets of *I. aggregata* in 1977 and 1978 (Table 1). The slope of the linear regression of seed sets on peak densities of *D. nelsonii* flowers over all years is positive, and the correlation between these variables is significant (Table 2*b*).

It could be argued that reduced fecundity of *I. aggregata* in 1977 and 1978 was also a subtle effect of drought rather than of reduced availability of hummingbird pollinators after failure of *D. nelsonii* flowering. However, census records suggest that activity of male broad-tailed hummingbirds (*Selasphorus platycercus* Swainson) was reduced in 1977 and 1978 relative to 1975 as predicted by the mutualism hypothesis. These birds, along with rufous hummingbirds (*S. rufus* Gmelin), are the major pollinators of *I. aggregata* around the RMBL[9], and this species is self-incompatible (1978 seed sets of self-pollinated flowers on five bagged plants compared with those of open-pollinated flowers on eight unbagged plants were 0.3±0.08 (n = 256) compared with 7.1±0.71 (n = 43). However, rufous hummingbirds are migratory transients who usually arrive after flowering of *D. nelsonii* and whose activity did not fluctuate substantially

Table 2 Linear regressions and correlations between seed sets, densities of flowers and census counts of hummingbirds

a Peak densities of *I. aggregata* flowers against peak densities of *D. nelsonii* flowers

I. aggregata = 0.08 (*D. nelsonii*) + 27.44
$r = 0.14$ d.f. = 2 $P > 0.5$ NS

b Raw *I. aggregata* seed sets against peak densities of *D. nelsonii* flowers

seed set = 0.15 (*D. nelsonii*) + 7.04
$r = 0.41$ d.f. = 183 $P < 0.001$

c Raw *I. aggregata* seed sets against overall census counts of broad-tailed hummingbirds

seed set = 0.58 (census count) + 3.65
$r = 0.27$ d.f = 136 $P < 0.01$

d Raw *I. aggregata* seed sets against late census counts of broad-tailed hummingbirds

seed set = 0.78 (census count) + 2.90
$r = 0.24$ d.f. = 136 $P < 0.01$

All regressions were run using mean values from Table 1, except that *I. aggregata* seed sets are original raw values rather than means for each year. Correlation coefficients and significance values are shown for the association between each set of variables. NS, not significant.

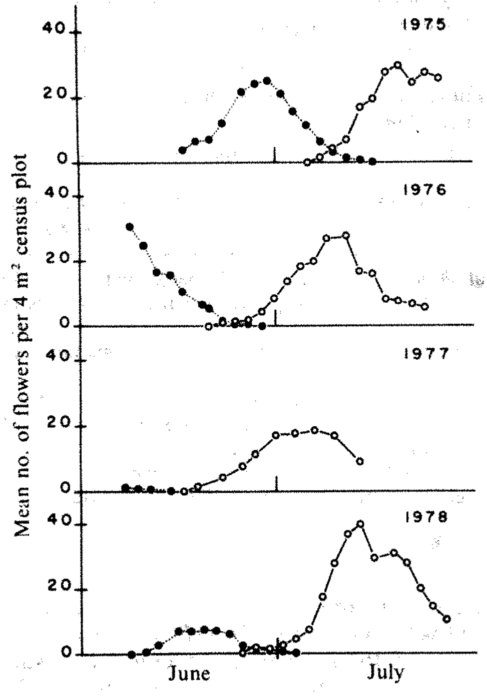

Fig. 2 Sequential flowering of *D. nelsonii* (●) and *I. aggregata* (○) at the RMBL during four consecutive summers. Note the poor flowering of *D. nelsonii* in 1977 and 1978.

between years (Table 1). In contrast, broad-tailed hummingbirds are breeding residents who colonise the RMBL area largely in response to flowering of *D. nelsonii*[27]. Slopes of linear regressions of *I. aggregata* seed sets on yearly mean census counts of broad-tailed hummingbirds are positive, and correlations between these variables are significant (Table 2*c*, *d*).

In contrast to competition for pollination, it is difficult to see how the mutualism discussed here could establish or maintain sequential flowering through selection acting on individual plants or even on alternate plant assemblages. We consider effective mutualism to be an unanticipated outcome, rather than a cause, of divergence in flowering times of sympatric species.

We thank M. V. Price, P. Feinsinger and H. G. Baker for valuable suggestions, M. V. Price for drafting the figures, and the Chapman Memorial Fund, Sigma Xi and the American Ornithologists' Union for grants to N.M.W. in support of the field studies.

'Time–intensity trading' in locust auditory interneurones

Jürgen Rheinlaender & Alfred Mörchen

Lehrstuhl für Allgemeine Zoologie, Ruhr-Universität Bochum,
Postfach 102148, 4630 Bochum, FRG

In the locust the firing rate of tympanal nerve fibres encodes the direction of the sound source, and this has been used as fundamental evidence for the directional sensitivity of each of the tympanal organs[1–4]. As there is a minute disparity between the two organs (in *Locusta* this distance is about 4 mm), it was generally accepted that the physical time cue—maximally about 10 µs—cannot be used for sound localisation. However, Mörchen *et al.* have found that in single receptor fibres of the locust, the magnitude of excitation is highly correlated with the latency of nervous activity[5]. In their study a sound source was moved around the animal and the latency of a neural discharge increased by up to 6 ms as the firing rate decreased. This 'neural time cue' exceeded the physical one by a factor of 100–1,000. Comparison of the inputs from the two organs shows that there are two neural codes available (spike count and latency), each of which can adequately specify the direction of the sound source. We report here that the subsequent synapses process this dual mode of directional coding and that both the rate of binaural spike discharges and latency differences influence the activity of auditory interneurones.

We recorded the responses of a pair of identified acoustic interneurones in *Locusta migratoria* from the connectives between the meso- and metathoracic ganglia. This pair of auditory units (type B_1)[6] is excited ipsilaterally and inhibited from the contralateral side, and thus it is appropriate for the study of binaural processing. To provide an effective uncoupling of the two organs the tympanal membranes were displaced by contact-mechanical stimulation. Two custom-made piezoelectric transducers (similar to those described elsewhere[7]) were used and driven with a sinusoidal signal of 69 kHz; such a frequency eliminates conventional acoustic stimulation of auditory receptor cells (compare ref. 8) but nevertheless activates them adequately (for control experiments see below). With this method the 'crosstalk barrier' between both ears was greater than 55 dB. In each experiment the activities from the units on both sides of the central nervous system (CNS) were recorded successively to calibrate the stimulus intensities of the two probes (for control experiments see below).

The effects of interaural time and intensity differences on the response of the auditory interneurone are shown in Fig. 1. The solid line represents equal stimulus intensities at both ears. By stimulating the ipsilateral (excitatory) ear alone, a maximal response was achieved; this corresponded to the binaural stimulus situation with the ipsilateral stimulus preceding the contralateral (inhibitory) stimulus in a range from 4 to 40 ms. When the inhibitory stimulus preceded the excitatory one the activation of this unit was completely suppressed (note that the steep slope of the curve occurred in a time window of ~ ±2 ms for either the ipsi- or contralateral stimulus leading). Thus the synaptic inputs of this interneurone are highly sensitive to time differences of the order of a few milliseconds. It was necessary for the inhibitory stimulus to precede the excitatory one by more than 80 ms for it to be completely ineffective (not shown in Fig. 1, for comparison see Fig. 2).

A decrease in the contralateral (inhibitory) stimulus of only 5 dB shifted the steep slope of the curve in Fig. 1 to the left (dotted line) where the midpoint is defined by simultaneous stimuli. This means that inhibitory effects were only effective when preceding excitation by more than 2 ms, but not suppressing the activity completely. When the contralateral stimulus was reduced by a further 5 dB, it had no effect on the response of the interneurone. However, when the intensity of the contralateral

0028-0836/79/430672—03$01.00

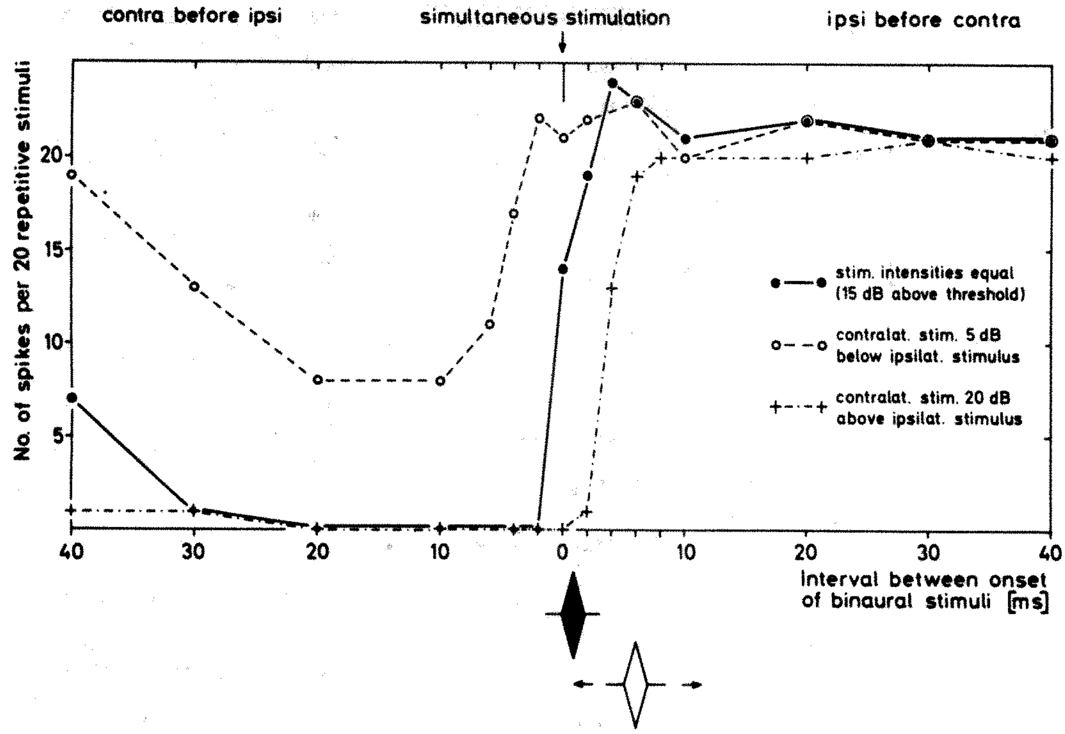

Fig. 1 Effects of interaural time and intensity differences on the response of an auditory interneurone in the locust to short contact-mechanical stimuli on the typanic membranes; activation by ipsilateral (◆), inhibition by contralateral (◇) stimulus (stimulus frequency 69 kHz, rise- and decay-time 1 ms, plateau 0 ms, repetition rate 1 per s), for further indications see other figure legends. Note that the steepest slope of the curves produced by various interaural time differences can be traded by changing the interaural intensities.

stimulus was increased relative to the ipsilateral one the steep slope of the curve shifted to the right (shown in Fig. 1 for 20 dB difference, dashed line). This means that with more intense contralateral stimuli the inhibition was effective even when it followed the ipsilateral stimulus by ~4 ms. (A further increase of the contralateral stimulus intensity had no additional effect on this curve.)

The data presented in Fig. 1 reveal that in the CNS of insects there is a phenomenon similar to the time–intensity trading well known for vertebrates (reviewed by Erulkar[9]). But in insects the 'time cue' is based on the physiological properties of scolopidian receptor cells and has another order of magnitude. Furthermore, the data show that within a given 'time and intensity window' such interneurones are highly sensitive to binaural changes. Specifically interaural time differences of the order of 4 to 6 ms and interaural intensity differences of about 20 dB will change the activity from maximal excitation to total inhibition.

The experiments with contact-mechanical vibration may present some technical problems (for more details see ref. 10). In particular, with bilateral processing, the question of whether there is symmetrical displacement of the two membranes, and the equivalence of acoustic and contact-mechanical stimulations have to be tested. To answer the first question a control measurement was performed in each experiment and the activities from equivalent units on each side of the CNS were recorded in succession. This procedure was necessary to define the neural thresholds of each unit to the vibratory stimulus, providing controlled stimulus intensities at both ears. In some cases (such

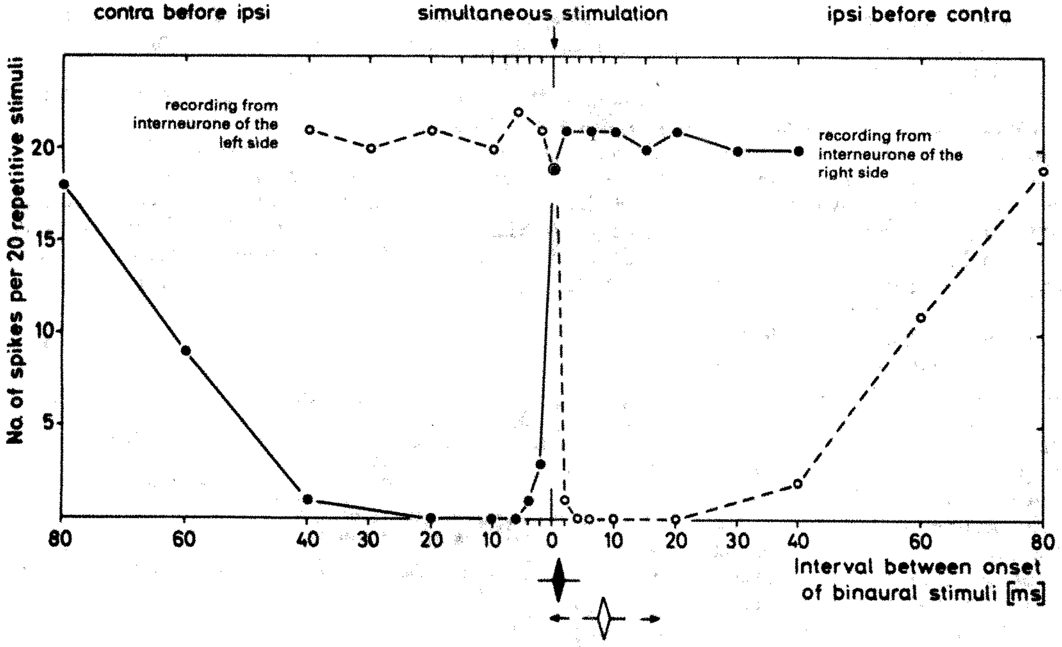

Fig. 2 Effects of interaural time difference on the response of a pair of auditory interneurones on either side of the CNS in the locust to short contact-mechanical stimuli on the tympanic membranes; activation by ipsilateral (◆), inhibition by contralateral (◇) stimulus, 15 dB above threshold respectively (further stimulus configurations see Fig. 1 legend). In each recording the 'leading' trigger and recording side have been reversed. Note the symmetry and the steepest slope of the curves near simultaneous stimulus onsets.

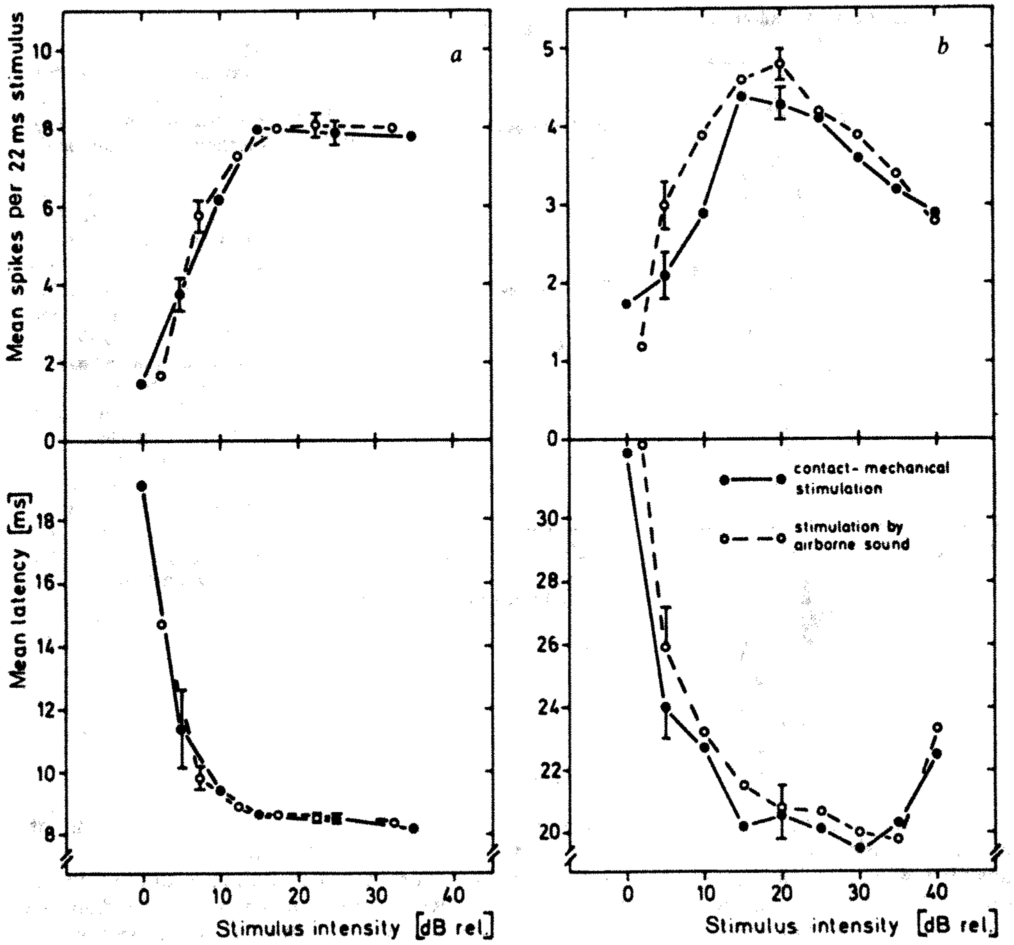

Fig. 3 Intensity and latency characteristics of a receptor cell (*a*) and an interneurone (*b*) of the locust for contact-mechanical stimulation on the tympanic membrane (vibrating frequency of 69 kHz) and stimulation by airborne sound at best frequencies (for *a*, 16 kHz; for *b*, 10 kHz); for both types of stimuli rise- and decay-time 1 ms, plateau 20 ms, repetition rate 1 per s. Each data point represents 10 stimuli. The abscissa gives the stimulus intensity referred to relative voltage at the vibrating probe (for *a*, 0 dB ≙ 42 $\mathrm{mV_{pp}}$; for *b*, 0 dB ≙ 21 $\mathrm{mV_{pp}}$) and sound pressure levels in the free-field (for *a*, 0 dB ≙ 47 dB SPL; for *b*, 0 dB ≙ 27 dB SPL). The displacement of the tip of the probe (movement forwards and backwards is about 2,200 Å for 3 $\mathrm{V_{pp}}$ input voltage and linear over the whole operating range (calibrated by laser vibratometry). This magnitude of displacement corresponds to physiological values as measured on the cricket ear[12]. The tip of the probe was perpendicularly placed at a point on the membrane, about 200 μm ventromedial to a dark cuticular landmark (this position was maintained in all experiments). When the probe was not in contact with the membrane, even the highest voltage used elicited no response; this indicates that only contact-mechanical and no inadvertent acoustic stimuli were effective.

as the experiments presented in Fig. 1) observations were repeated for the corresponding unit on the other side of the CNS, maintaining both stimuli at 15 dB above threshold. In Fig. 2 the corresponding curves are shown for recordings from the right (solid line) and left (dashed line) interneurones. Since the two curves are nearly identical over the whole time axis, this example implies a symmetrical stimulus situation at both ears.

To deal with the second problem, we measured the response characteristics of several receptor cells and some interneurones, each stimulated with the piezotransducer and, after its removal, by airborne sound. As shown by the example in Fig. 3*a*, the receptor cell exhibited identical intensity and latency characteristics to the two stimuli (for similar results in moths see ref. 11). These data strongly suggest that the magnitude of neural excitation at the receptor can be finely controlled by both types of stimulus, which is important for the interpretation of Fig. 1 (see above). The coincidence between the two types of curve was found in both low- and high-frequency receptors. In Fig. 3*b* the corresponding curves for an auditory interneurone are shown. Although this interneurone exhibits a rather complicated intensity characteristic, both pairs of curves are similar. It is evident that at both neuronal levels, in the given circumstances, the contact-mechanical stimulation can be made equivalent to the acoustic free-field situation.

Referring to Fig. 1 we emphasise that by the contact-mechanical stimulation technique the binaural spike code can be separated from the binaural latency difference. The former code could be controlled by stimulus intensity (see Fig. 3), and the latter one was manipulated by experimental time delays between the two stimuli. Clearly both kinds of neuronal code control the activity of the interneurone. This is also true in free-field conditions, because with ipsilateral sound, the excitation of the ipsilateral receptors precedes inhibition from the contralateral side, which is also smaller in magnitude. In contralateral stimulus conditions this situation changes drastically, as now the greater inhibition precedes reduced excitation. Thus both cues—intensity and the time of arrival of the neural response in the CNS—have important, mutually reinforcing effects on synaptic transmission and ensure the optimal use of the peripherally processed directional information.

This work was supported by the Deutsche Forschungsgemeinschaft as a part of the program Sonderforschungsbereich 114 (Bionach), Bochum. We thank Professor A. Michelsen, University of Odense and the AEG-Forschungslabor, Frankfurt/M for calibrating our probes by laser vibratometry and Dr D. B. Lewis for loan of the first prototypes. We also thank Professor A. Michelsen, Dr H. C. Gerhardt, Dr R. B. Coles and Professor J. Schwartzkopff for criticising the manuscript and Mrs B. Brücher and Mrs A. Akkermann for technical assistance.

Ionic basis of the receptor potential in a vertebrate hair cell

D. P. Corey & A. J. Hudspeth

Division of Biology, California Institute of Technology, Pasadena, California 91125

Vertebrate hair cells, the primary receptors of auditory, vestibular and lateral-line organs, occur in epithelia which separate fluids of differing ionic composition. The apical surfaces of hair cells, on which the mechanosensitive hair bundles are situated, face a high-K^+ fluid (termed endolymph in the inner ear); the basolateral surfaces instead contact fluid (perilymph or a related substance) of a composition similar to that of other extracellular fluids[1-3]. The universal occurrence of high-K^+ fluid on the apical surfaces of hair cells in vertebrates has been taken as evidence that it is important for the transduction process, in particular that it relates to the ionic specificity[4] of the conductance change[5] underlying the receptor potential. There is, however, conflicting experimental evidence regarding this specificity. K^+ has generally been thought to carry the receptor current, as replacement of endolymph with perilymph in the guinea pig cochlea abolishes the extracellularly recorded microphonic potential[6]. Yet microphonic potentials, as well as intracellular receptor potentials, have been recorded in other preparations when the apical surfaces of the hair cells faced instead a high-Na^+ saline, and thus when the electrochemical gradient for K^+ was near zero[5,7]. Ca^{2+} has also been proposed to carry the receptor current[8], but its concentration is quite low in endolymph[3], particularly that of the mammalian cochlea[9]. We present evidence here that the receptor current in a vertebrate hair cell is carried *in vivo* by K^+, but that the transduction channel is in fact nonspecific, being permeable to Li^+, Na^+, K^+, Rb^+, Cs^+, Ca^{2+}, and at least one small organic cation.

Hair cells were prepared for intracellular recording as described previously[5,10]. Sacculi were removed from adult bullfrogs and their otolithic membranes peeled away after loosening by mild proteolysis (incubation for 60 min with 0.03 mg ml^{-1} subtilopeptidase A, EC 3.4.4.16, at 22 °C). The tissue was positioned in an experimental chamber with standard saline on all cell surfaces and viewed with Nomarski differential interference contrast optics. Individual hair cells were penetrated by two glass microelectrodes, each 100–150 MΩ in resistance, connected to a simple voltage clamp circuit. To stimulate each impaled cell, its hair bundle was deflected with a fine glass probe (0.2 μm tip diameter) inserted horizontally between the kinocilium and the rest of the hair bundle. Probes were moved by an electronically controlled, two-dimensional stimulator, over a distance of 1–2 μm, with a 10-Hz, triangle waveform.

We first measured the current-voltage relationship for unstimulated hair cells (Fig. 1). The input resistance measured with two electrodes was 200–300 MΩ at a holding potential of −60 mV. Because the resistance was higher (200–900 MΩ) if measured with one electrode and an active bridge circuit, much of the apparent membrane conductance at this potential resulted from penetration damage. At membrane potentials more positive than about −50 mV, however, the resistance dropped to 6–7 MΩ. This conductance increase was largely blocked by 1 mM 3,4-diaminopyridine[11], and is evidently a voltage-dependent K^+ conductance. Such outward or delayed rectification may explain the rather small receptor potentials seen in some hair cell preparations[12,13]: because of the change in slope conductance, a receptor current which generates a receptor potential of 20 mV in bullfrog hair cells at a resting potential of −60 mV produces only 0.5 mV at −40 mV. Figure 1 shows an additional conductance increase, an inward or anomalous rectification, at potentials below −100 mV. Such a rectification has been hypothesised to explain certain aspects of electrical behaviour of the mammalian cochlea[14], but has not previously been demonstrated for vertebrate hair cells.

The stimulus-associated current, or receptor current, was measured by presenting periodic mechanical stimuli of saturating amplitude while clamping to various potentials. The receptor current at the holding potential of −60 mV ranged from 45 to 205 pA with a mean of 98 pA (±37 pA, s.d., $n = 28$ cells) and with the larger values more representative of healthy cells. Variation in the measured current was caused both by decline in the viability of a cell during prolonged recording and by mechanical drift of the stimulus probe with respect to the responsive range of the hair bundle. The voltage dependence of the receptor current was consequently determined by comparing the receptor current at a test potential to the current at the holding potential immediately before and after the potential step. The receptor current at −60 mV was normalised to 100 pA for each cell, and the receptor current at each test potential then scaled by the same amount. An implicit assumption in this analysis is that the mechanical sensitivity is not also voltage-sensitive, for instance that the responsive range of the hair bundle does not shift as the cell is depolarised.

A representative series of clamp records is shown in Fig. 2*a*. The receptor current reverses its direction from inward to outward at a membrane potential between −9 and +11 mV. Figure 2*b* combines normalised data from 24 cells; a linear regression fit to these data indicates a reversal potential of −2 mV. This is not the equilibrium potential for Na^+, K^+, or Ca^{2+}, since a standard, 124-mM Na^+ saline solution[5] faced all cell surfaces during these experiments. It could, however, result from a stimulus-dependent conductance that is nonspecific—that has a limited ability to discriminate among cations.

We consequently tested several cations using an *in vitro* microphonic technique[15]. The macular epithelium of the sacculus was positioned across a hole between two chambers, so as to separate them ionically and electrically. The potential across

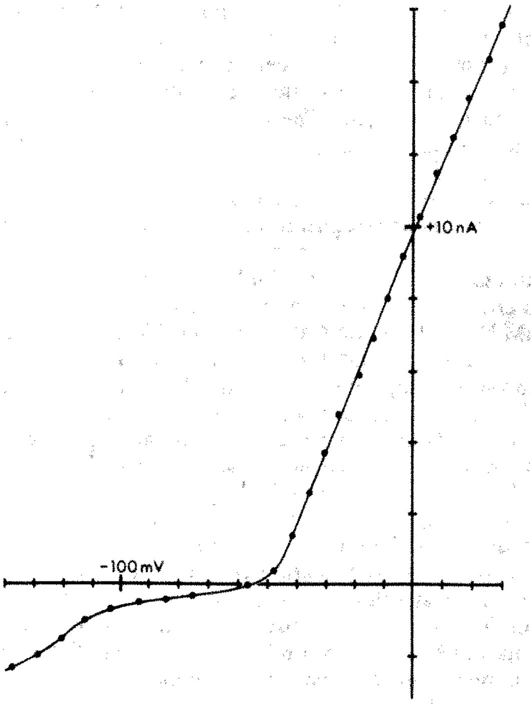

Fig. 1 Current-voltage relationship for a saccular hair cell, measured 50 ms after the start of a voltage step. Inward current is shown as negative. The holding potential was −60 mV. The striking outward rectification which occurs above −50 mV was blocked by 3,4-diaminopyridine and probably corresponds to the delayed rectification of most neurones. Inward or anomalous rectification is evident at potentials below −100 mV.

0028-0836/79/430675—03$01.00

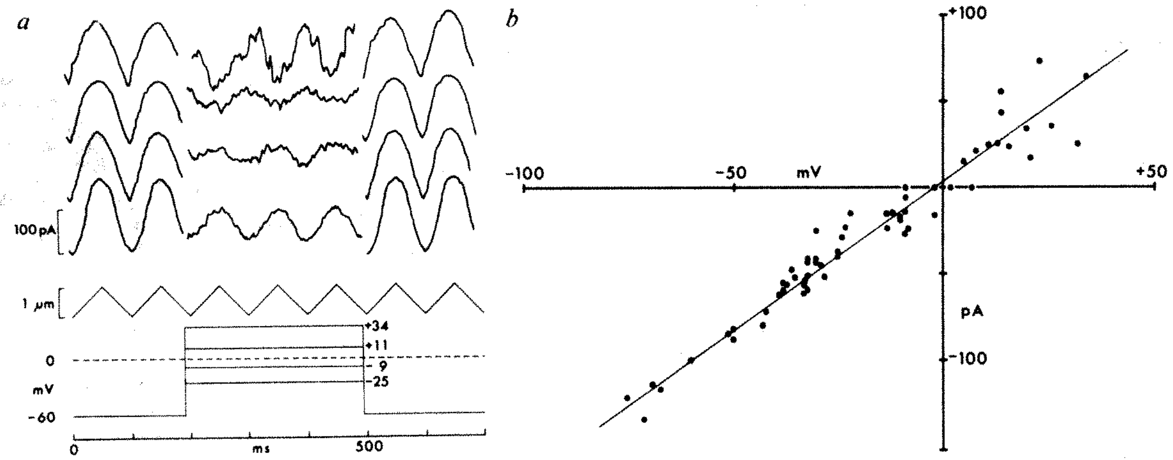

Fig. 2 *a*, Receptor currents at a holding potential of −60 mV and at test potentials of −25, −9, +11, and +34 mV; inward current is shown as negative. The membrane potential was held at −60 mV for 200 ms, clamped to the test potential for 300 ms, and returned to the holding potential. Each trace represents the average of 10 test steps. Ionic currents that were not stimulus-dependent were electronically subtracted before measuring the receptor current. The hair bundle was continuously moved with a 1.1-µm, 10-Hz, triangle-wave stimulus, shown below the current records; downward represents a deflection toward the kinocilium. *b*, Magnitude of the receptor current as a function of membrane potential; normalised data from 24 cells. The line is a linear regression fit to the data ($r^2 = 0.97$); its zero-current intercept, the reversal potential, is −2 mV. The external fluid was standard, high-Na^+ saline, so that the reversal potential is not the equilibrium potential of Na^+, K^+, or Ca^{2+}.

the epithelium was monitored with an electrode in each chamber; a second pair of electrodes was used to pass current to clamp the transepithelial potential at zero. Measuring the transepithelial current, rather than the transepithelial potential, avoided variations in response amplitude caused by slow changes in epithelial resistance. Hair cells were stimulated *en masse* by moving the otolithic membrane, which remained attached to the hair bundles, with a glass probe driven by a piezoelectric element. The stimulus was a saturating step displacement of amplitude 1.5 µm and duration 1 ms. The otolithic membrane can follow this fast stimulus, and the microphonic current turns on and off in much less than this time[15]. The charging time of the hair cell membrane is much longer, however, so that the intracellular potential should change only slightly during the pulse. The measured current is accordingly dependent on the resting potential and the permeability to the test ion, but not on voltage-sensitive conductances that are secondary to the receptor potential.

The chambers were separately perfused with a test solution on the apical side (130 mM of the relevant monovalent cation, 0.25 mM Ca^{2+}, 130 mM Cl^-, 3 mM D-glucose, 1 mM HEPES) and an artificial perilymph on the basolateral side (3.63 mM K^+, 122 mM Na^+, 1.36 mM Ca^{2+}, 0.68 mM Mg^{2+}, 130 mM Cl^-, 3 mM D-glucose, 1 mM HEPES). The apical surfaces of hair cells and supporting cells are bounded by tight junctions, which limit the exchange of ions between the two chambers.

All of the alkali cations supported the microphonic current. The mean relative signal amplitudes from eight experiments were: Li^+, 0.9; Na^+, 0.9; K^+, 1.0; Rb^+, 1.0; and Cs^+, 1.0. Ammonium ion (NH_4^+) was more permeant, with a relative amplitude of 1.3. To establish whether still larger ionic species could traverse the transduction channel, we bathed the apical surface with test solution containing 130 mM tetramethylammonium ion (TMA). This reduced the microphonic current to 0.2 of its value for 130 mM K^+, suggesting that TMA can pass through the transduction channel, although less readily than the alkali cations. To confirm this observation, TMA was tested on single cells using the intracellular voltage clamp method. The reversal potential, with 130 mM TMA on all cell surfaces, was −25 mV. Assuming that the extracellular TMA activity is roughly the same as the intracellular K^+ activity, this indicates a channel permeability to TMA about 0.4 that of K^+ (refs 16, 17). The fact that the permeabilities estimated by ionic current and by reversal potential are not equal suggests that TMA partially blocks the transduction channel[18].

The ability of one divalent ion, Ca^{2+}, to pass through the transduction channel was also demonstrated by extracellular recording. With 87 mM $CaCl_2$ in the test solution at the apical surface of the hair cell, the microphonic current was 0.3 that produced by 130 mM K^+. Because its concentration in endolymph is very low, Ca^{2+} can carry very little of the receptor current *in vivo*. Ca^{2+} does seem, however, to be a necessary cofactor for the response[5,8]: with a 130-mM K^+ saline, the microphonic current was abolished if the Ca^{2+} concentration was reduced below about 10 µM. Sr^{2+} replaces Ca^{2+} in this role, but Mg^{2+} and Ba^{2+} do not.

Because the transduction channel in frog saccular hair cells is nonspecific, the transduction current *in vivo* will be carried by cations approximately in proportion to their concentrations in endolymph. K^+, the predominant ion, will normally carry most of the current. The channel is equally permeable to the other alkali cations, however, and moderately permeable to Ca^{2+} and to an organic cation, TMA. As the unhydrated diameter of TMA is 0.54 nm, the channel interior must be at least this large. It therefore resembles the nonspecific, acetylcholine-activated channel of the motor endplate, which has an internal diameter of at least 0.65 nm (ref. 19).

It remains to be seen whether the transduction channels of all vertebrate hair cells are comparably nonspecific. The fact that Na^+ can support transduction in the goldfish sacculus[7] suggests that the channels in this organ are also nonspecific. The argument that ions other than K^+ cannot carry transduction current in the mammalian cochlea rests on the observation that substitution of Na^+ for K^+ in cochlear endolymph gradually but irreversibly blocks the response[6]. This might, however, reflect secondary effects of Na^+ accumulation on hair cells, such as the metabolic work required to pump this ion out of cells, rather than an inability of Na^+ to carry receptor current into cochlear hair cells. Inasmuch as the hair cells of lower vertebrates share with those of the cochlea a transduction process operating in high-K^+ fluid, mediated by stereocilia[10], and capable of great speed[15], it seems likely that the transduction channel of cochlear hair cells is also nonspecific in its ionic selectivity.

We thank Dr S. J. Krasne for helpful discussions, Mr J. H. R. Maunsell for assistance with data processing, and Mr R. Jacobs for technical assistance. This work was supported by NIH grants NS-13154 and GM-07616 and by the Ann Peppers and William Randolf Hearst Foundations.

Inhibition of platelet aggregation by native and desialised alpha-1 acid glycoprotein

Michael Costello, Barry A. Fiedel & Henry Gewurz

Department of Immunology, Rush University and Department of Microbiology and Immunology, University of Illinois at the Medical Center, Chicago Illinois 60612

The alpha-1 acid glycoprotein (orosomucoid; AAG) is a normal constituent of human plasma ($650 \pm 215\ \mu g\ ml^{-1}$) which increases in concentration as much as fivefold in association with acute inflammation and cancer, and thus is recognised as an acute phase protein[1,2]. AAG consists of a single polypeptide chain, has a molecular weight of 44,100, and contains ~45% carbohydrate including 12% sialic acid; it is the most negatively charged of the plasma proteins[3]. Certain of the biological properties of AAG are related to its sialic acid content[1,3]; thus, clearance and immunogenicity of AAG are markedly increased on desialisation[4,5]. The biological functions of AAG are largely unknown. AAG has the ability to inhibit certain lymphocyte reactivities including blastogenesis in response to concanavalin A, phytohaemagglutinin and allogeneic cells[6], and these inhibitory effects are enhanced in association with desialisation[7]. In view of these observations, a report that unphysiologically large (5–15 mg ml^{-1}) amounts of AAG inhibit the platelet aggregation induced by ADP and adrenaline[8], and evidence that a sialic acid-deficient species of AAG appears elevated in several chronic disease states[9,10], we compared the effects of AAG and its desialised counterpart (AAG-D) on platelet aggregation. We report that desialisation of AAG is associated with increased expression of activity inhibitory to the platelet aggregation otherwise observed on stimulation with ADP, collagen or thrombin.

AAG was isolated from human pleural fluids as described previously[6]. The purity of the four AAG preparations tested was established by SDS-polyacrylamide gel electrophoresis, immunoelectrophoresis and column chromatography on Sephadex G-75 and DEAE-cellulose. Desialisation was performed using *Vibrio cholerae* neuraminidase according to Schmid[11], with subsequent removal of the neuraminidase by reisolation of the AAG using DEAE-cellulose column chromatography; >75% loss of sialic acid[12] and 52% decrease of relative mobility on electrophoresis in polyacrylamide gels[13] were observed. Absence of residual neuraminidase activity in the AAG-D preparations was established by incubation with native AAG as the substrate using conditions optimal for enzyme activity; no neuraminidase activity was detected (<0.017 units per mg AAG-D). The standard platelet reaction mixtures consisted of 500 μl platelet-rich plasma (PRP), 200 μl of a dilution of AAG or AAG-D (in phosphate-buffered saline) and various amounts (in 10–15 μl) of the aggregating agent; the platelets were preincubated with AAG or AAG-D in the aggregometer for 30 s before stimulation with ADP, acid-soluble collagen[14], or thrombin. In experiments involving platelet activation by thrombin, 500 μl of a washed platelet suspension ($3.0 \times 10^8\ ml^{-1}$) was used in place of PRP[15].

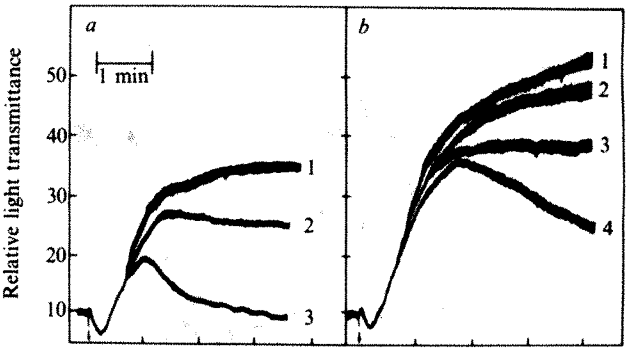

Fig. 1 Platelet aggregation induced by ADP at 12 μM (*a*) and 25 μM (*b*), and its inhibition by AAG and AAG-D. In *a*, curve 1 represents the buffer control; curve 2 inhibition by 2 mg ml^{-1} AAG; and curve 3 inhibition by 2 mg ml^{-1} AAG-D. In *b*, curve 1 represents the buffer control; curve 2 inhibition by 2 mg ml^{-1} AAG; curve 3 inhibition by 0.1 mg ml^{-1} AAG-D; and curve 4 the inhibition observed in the presence of 0.5–2.0 mg ml^{-1} AAG-D. AAG-D was substantially more inhibitory than the native molecule in all conditions tested.

The addition of either AAG or AAG-D (2 mg ml^{-1}) to PRP resulted in inhibition of the platelet aggregation otherwise observed on challenge with 12 μm ADP (Fig. 1*a*). AAG-D was substantially more inhibitory than native AAG at all doses of the glycoprotein tested, with inhibition directly proportional to the concentration of AAG and AAG-D and inversely proportional to the intensity of the ADP challenge stimulus. Thus, on challenge with a larger amount (25 μM) of ADP, 2 mg ml^{-1} AAG was no longer inhibitory, while AAG-D remained inhibitory even at concentrations as low as 50 μg ml^{-1}; concentrations of AAG-D to 2 mg ml^{-1} did not induce substantially greater degrees of inhibition but did bring about deaggregation of the stimulated platelets (Fig, 1*b*). The inhibitory effects of AAG and AAG-D were directed preferentially against the secondary wave of platelet aggregation, although with low (4 μM) ADP stimulation a minimal inhibitory effect on the primary aggregation wave also was observed.

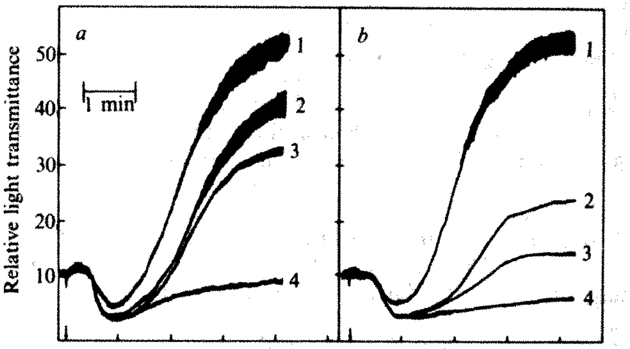

Fig. 2 Platelet aggregation induced by 9 μg ml^{-1} acid-soluble collagen and its inhibition by AAG (*a*) and AAG-D (*b*). In *a*, curve 1 represents the buffer control, while curves 2, 3 and 4 represent stimulation in the presence of 0.05, 0.5 and 2.0 mg ml^{-1} AAG, respectively. In *b*, curve 1 represents the buffer control, and curves 2, 3 and 4 show stimulation in the presence of 0.05, 0.1 and 0.5 mg ml^{-1} AAG-D, respectively. AAG-D again was substantially more inhibitory than the native molecule.

0028–0836/79/430677—02$01.00

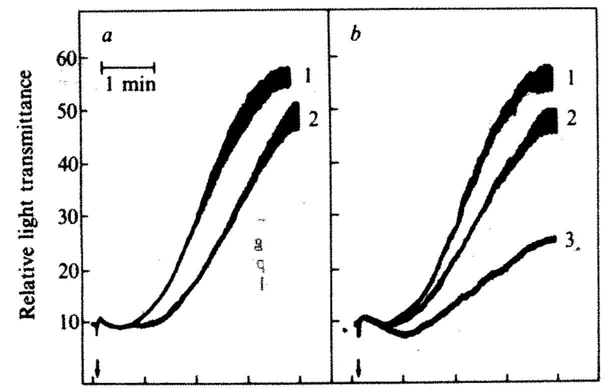

Fig. 3 Platelet aggregation induced by 0.014 U ml^{-1} bovine topical thrombin and its inhibition by AAG (*a*) and AAG-D (*b*). In *a*, curve 1 represents the buffer control, and curve 2 represents stimulation in the presence of 1 mg ml^{-1} AAG. In *b*, curve 1 represents the buffer control, and curves 2 and 3 show stimulation in the presence of 0.25 and 1 mg ml^{-1}, respectively. AAG-D again was substantially more inhibitory than the native molecule.

Both AAG and AAG-D were also capable of inhibiting the platelet response to collagen, with AAG-D again much more inhibitory than the native molecule (Fig. 2). Thus, AAG-D at 50–100 μg ml^{-1} markedly inhibited platelet aggregation, while native AAG was only minimally inhibitory at comparable concentrations; however, larger amounts of AAG (2 mg ml^{-1}) were fully inhibitory. Inhibition was characterised by decreased rates and extents of aggregation with a minimal effect on the onset of platelet shape change. The addition of AAG and particularly of AAG-D also resulted in decreased secretion of platelet serotonin on stimulation with ADP or collagen.

AAG and AAG-D also inhibited platelet aggregation induced by thrombin and AAG-D was again the more inhibitory with 250 μg ml^{-1}, compared to 1 mg ml^{-1} of native AAG, needed for significant inhibition (Fig. 3). Decreased inhibition was observed when the concentration of the thrombin challenge dose was increased. In controls for the above experiments platelet viability was unaltered as monitored by ^{51}Cr release, and thus could not account for the inhibitory effects observed. Further, the addition of neuraminidase in amounts (0.03–0.09 units ml^{-1}) up to fivefold greater than the minimum detectable in the assays used in this work had either no effect on, or enhanced, both ADP- and thrombin-induced platelet aggregation.

The mechanism(s) by which AAG inhibits the platelet response to ADP, collagen and thrombin is not yet known, nor is the manner in which desialisation seems to evoke further or enhance this inhibitory activity. Thus, removal of sialic acid residues may directly alter the exposure or effectiveness of appropriate reactive sites or indirectly favour a further critical modification of AAG such as its aggregation[16]. Moreover, we do not yet know the relative activities of the polymorphic or altered forms of AAG that have been observed in various sera and fluids[3,9,10]. Nonetheless, it is clear that both native and desialised AAG share with another acute phase protein, the C-reactive protein or CRP, the capacity to inhibit platelet responsiveness[14,15], and like CRP the effects of AAG are directed predominantly to events critical for the secondary wave of platelet aggregation. The present results thus point to AAG as a potentially significant modulator of platelet responsiveness, suggest desialisation or an associated alteration of the molecule as a mechanism by which this biological potential is evoked and/or enhanced, and support the hypothesis that the acute phase response represents, at least in part, a coordinated system to limit, modulate and/or otherwise direct host immune responses during periods of intense inflammation and tissue destruction.

This work was supported in part by NIH grants AI-12870 and HL-23457. H.G. holds the Thomas J. Coogan Chair in Immunology at the Rush Medical Center established by Marjorie Lindheimer Everett.

Cell-mediated immunity to *Theileria*-transformed cell lines

Veterinary Research Department, Kenya Agricultural Research
Institute, Muguga

In East and Central Africa the protozoan parasite *Theileria parva* causes a disease of cattle called East Coast fever (ECF). In Kenya alone between 60,000 and 85,000 cattle die from ECF every year[1]. Infected animals can recover from ECF either naturally[2] or after treatment with tetracyclines[3] or menoctone[4] and are subsequently able to resist challenge with the homologous strain of parasite. That this acquired resistance is due to cell-mediated rather than humoral immunity has been suspected[5,6] but never decisively shown. A major difficulty in studying immunity to ECF has been the lack of inbred animals for studying *Theileria*-specific immunity in the absence of allogeneic histocompatibility barriers. We have avoided this problem by measuring cell-mediated immune responses in a syngeneic system *in vitro*. Unidirectional mixed lymphocyte cultures (MLC) were set up using bovine peripheral blood lymphocytes (PBL) as responder cells and autologous cell lines transformed *in vitro* by *T. parva* as stimulator cells. In these cultures, DNA synthesis was induced in PBL from both normal and *Theileria*-immune animals. However, cytotoxic lymphocytes were induced only in cultures containing responder lymphocytes from *Theileria*-immune cattle. The results show that *Theileria*-transformed cells express antigens which are recognised by effector cells and provide evidence that cell-mediated cytotoxic mechanisms function in immunity to ECF.

By culturing cell suspensions from lymph nodes, spleen or peripheral blood of *Theileria*-infected cattle, transformed lymphoblastoid cell lines can be obtained[7]. Such cell lines can also be obtained by infecting normal bovine lymphocytes *in vitro* with *Theileria* sporozoites[8]. It is likely, therefore, that these cell lines represent the schizogonous stage of the parasite in the host animal which is characterised by the presence of macroschizonts in the transformed lymphocyte. Of more than 10 different *Theileria*-transformed cell lines examined by immunofluorescence, all were surface immunoglobulin negative and stained positively with fluoresceinated peanut agglutinin (G. E. Roelants *et al.* unpublished). Thus we believe that the *Theileria*-infected cells are bovine T lymphocytes[9].

Table 1 Stimulation of bovine lymphocytes by syngeneic *Theileria*-transformed cell lines

	Cell combination	Mean c.p.m.	Maximum stimulation ratio		Cell combination	Mean c.p.m.	Maximum stimulation ratio
A	PBL$_{784}$ × medium	117	—	*B*	PBL$_{951}$ × medium	241	—
	PBL$_{784}$ × PBL$_{784(R)}$	105	—		PBL$_{951}$ × PBL$_{951(R)}$	252	—
	LINE$_{784(R)}$ × medium	74	—		LINE$_{951(R)}$ × medium	286	—
	PBL$_{784}$ × LINE$_{784(R)}$	25,039	238.5		PBL$_{951}$ × LINE$_{951(R)}$	16,703	66.3
					PBL$_{989}$ × PBL$_{951(R)}$	5,061	21.0

Lymphocytes were separated from heparinised peripheral blood of female Friesian animals 951 and 784 by centrifugation through Ficoll–Paque (Pharmacia) and adjusted to 2.5×10^6 cells per ml in RPMI-1640 medium containing heat-inactivated fetal calf serum (5%), glutamine (2mM), 2-mercaptoethanol (5×10^{-5} M), penicillin (100 μg ml^{-1}), streptomycin (100 IU ml^{-1}) and HEPES buffer (10mM)[9]. Volumes of 0.1 ml were dispensed in triplicate into wells of Falcon 3040 flat-bottomed microplates. One hundred μl of medium alone or of a suspension of irradiated syngeneic *Theileria*-transformed cells (2.5×10^5 cells ml^{-1}) were added to the appropriate microwells. The subscript (R) indicates that the cells were irradiated with 5,000 R from a caesium source. The microplates were incubated at 37 °C in 5% CO_2 in air and at 48, 96, 144 and 192 h, 0.5 μCi ^{125}IUdR was added to each well. Sixteen hours later, cultures were collected onto glass fibre filters using a Skatron multiple sample harvester. Filters were dried under an IR lamp and counted for 1 min in a γ counter. Mean counts per minute were determined and stimulation ratios calculated as mean c.p.m. in PBL–syngeneic line combinations/mean c.p.m. in PBL–syngeneic PBL combinations. Stimulation ratios were determined for each time point but only the maximum stimulation ratios were shown here (peak was at day 6 for both experiments shown). In preliminary experiments, eight batches of fetal calf sera were tested at 5, 10 and 20% final concentration. One batch (used at 5% final concentration) gave the highest stimulation ratios and was used in all further experiments. Various cell concentrations, stimulator: responder cell ratios and irradiation doses were also tested and optimal conditions determined before starting the experiments presented in this paper. The data shown are representative of data obtained in four experiments performed with PBL and cell line from animal 784 and in six experiments with PBL and cell line from animal 951. The cell lines used as stimulators were derived by infecting lymphoid cells *in vitro* with sporozoites of *T. parva* from ground up ticks using the method of Brown *et al.*[8]. Lymph nodes were removed from Friesian heifers 951 and 784 and their cells infected from a common pool of *T. parva* (Muguga). The lymphoblastoid lines were maintained by twice weekly passage in Eagle's minimal essential medium with Earle's salts and 20% fetal calf serum. For use in MLC and for generation of cytotoxic lymphocytes, the cell lines were transferred and grown in RPMI-1640 medium containing 10% heat-inactivated fetal calf serum and were subcultured every two days to ensure healthy cells. All cattle used were judged to be healthy by the veterinary staff at the Kenya Agricultural Research Institute. Animals which were known to be *Theileria*-immune had high levels of anti-macroschizont antibodies (detected by indirect immunofluorescence) in their sera. Those which were considered non-immune were clinically normal and their sera contained no detectable anti-macroschizont antibodies.

It is thought that host cells must be infected with *Theileria* parasites before immunity can be achieved[10]. This led us to believe that the infected lymphocytes carry infection- or transformation-associated antigens on their surface and that these antigens are recognised by the host immune system. To test for such antigens, DNA synthesis was measured in MLCs containing syngeneic responder–stimulator combinations as shown in Table 1. *Theileria*-transformed cells stimulated ^{125}I-iododeoxyuridine (^{125}IUdR) uptake in autologous PBL from normal or *Theileria*-immune animals and with the same kinetics in each case. Normal PBL were stimulated to similar degrees with autologous and allogeneic *Theileria*-transformed stimulator cells (data not shown). The stimulation ratio in cultures containing the allogeneic PBL combination (PBL$_{784}$ × PBL$_{951(R)}$) was much lower than that obtained when the allogeneic *Theileria*-transformed cells were used as stimulators suggesting that the high stimulation was caused by special properties of the transformed cells and not simply by differences in normal histocompatibility antigens. Autoradiography showed that DNA synthesis was increased in the nuclei of responder lymphocytes (G. E. Roelants and T.P., unpublished). This stimulation was probably caused by antigens on the surface of viable stimulating cells since culture supernatants from MLCs had no effect on DNA synthesis of responder cells (Table 2). Addition of freshly prepared free macroshizonts to PBL cultures also failed to stimulate DNA synthesis. We did not detect schizonts in dividing cells in Giemsa stained preparations from 6–10 day MLCs showing that transformation of normal PBL had not occurred. Transformed cells, killed by heating or treated with the compound 993C (a 2-cycloalkyl-3-hydroxy-1, 4-naphthoquinone, Wellcome) to eliminate the schizonts, failed to stimulate DNA synthesis in MLC (Table 3). Compound 993C is selectively toxic for the macroschizont in the transformed cell and thereby stops parasite-induced proliferation but leaves the cells in a viable but non-transformed state[11]. These results suggest that antigens present on the surface of *Theileria*-transformed cells are involved in stimulation of normal syngeneic PBL and that the antigens are *Theileria*-associated and not due solely to culture *in vitro*. In addition, the heat-treatment experiment shows that viable stimulator cells are required, a feature of a true mixed lymphocyte reaction (MLR)[12].

Table 2 The effect of MLR culture supernatants on DNA synthesis in bovine lymphocytes

	Cell combination/supernatant	Mean c.p.m.	Stimulation ratio
A	PBL$_{951}$ + fresh medium	324	-
	+ supernatant 1	331	-
	+ supernatant 2	361	-
	+ supernatant 3	301	-
	+ supernatant 4	302	-
	+ supernatant 5	302	-
B	PBL$_{951}$ × LINE$_{951(R)}$ + fresh medium	2,568	12.7
	+ supernatant 1	2,201	10.9
	+ supernatant 2	2,201	11.4
	+ supernatant 3	1,999	9.9
	+ supernatant 4	2,109	10.5
	+ supernatant 5	1,990	9.9

Various cell combinations were set up in microplates following the procedure outlined in Table 1 legend. After incubation for 5 days, supernatants were removed from the culture wells and 100-μl aliquots (either neat or after concentrating fivefold with an Amicon UM-2 filter) were added to microwells containing normal PBL (*A*) or mixed lymphocyte cultures (*B*). Six days later, ^{125}IUdR was added to the microwells and the well contents collected as described in Table 1 legend. Supernatants were prepared from the following cell combinations: (1) PBL$_{951}$ × PBL$_{951(R)}$ (2) PBL$_{951}$ × LINE$_{951(R)}$ (3) PBL$_{951(R)}$ × LINE$_{951(R)}$ (4) LINE$_{951(R)}$ × medium (5) LINE$_{951}$ × medium. In experiment *B*, the control culture (PBL$_{951}$ × PBL$_{951(R)}$ showed 201 mean c.p.m.

Table 3 The effect of heating and drug treatment of *Theileria*-transformed stimulating cells in MLR

Cell combination	Mean c.p.m.	Stimulation ratio
PBL$_{951}$ × PBL$_{951(R)}$	340	1.0
PBL$_{951}$ × LINE$_{951(R)}$	2,860	8.4
PBL$_{951}$ × LINE$_{951(R)993C\ \mathrm{treated}}$	407	1.2
PBL$_{951}$ × LINE$_{951(R)\ \mathrm{heat\ treated}}$	238	0.7

Cell combinations were set up in microplates as described in Table 1 legend. Some stimulator cells were heat-killed (as assessed by Trypan blue exclusion) by incubating at 56 °C in a water bath for 45 min. Drug treatment of stimulator cells was performed by incubating 5×10^7 *Theileria*-transformed cells at 37 °C for 48 h with 1μg ml^{-1} final concentration of the compound 933C after which they were washed three times. The cells were 94% viable after treatment. The stimulation of DNA synthesis was assessed at days 3, 4, 5 and 6. Only the results from day 6 are shown here although the same pattern of stimulation was seen at all time points. The data shown are representative of data obtained in three experiments.

A positive MLR represents the cognitive and proliferative phase of an immune response[13]. However, proliferation of cells is not in itself evidence for functional immunity. For this reason, we tested for cell-mediated lysis of *Theileria*-transformed cell lines by using cells from MLCs as effectors in ^{51}Cr-release assays (Fig. 1). Cytotoxic activity was only detected after secondary stimulation *in vitro* of PBL from immune animal 713. Cytotoxic

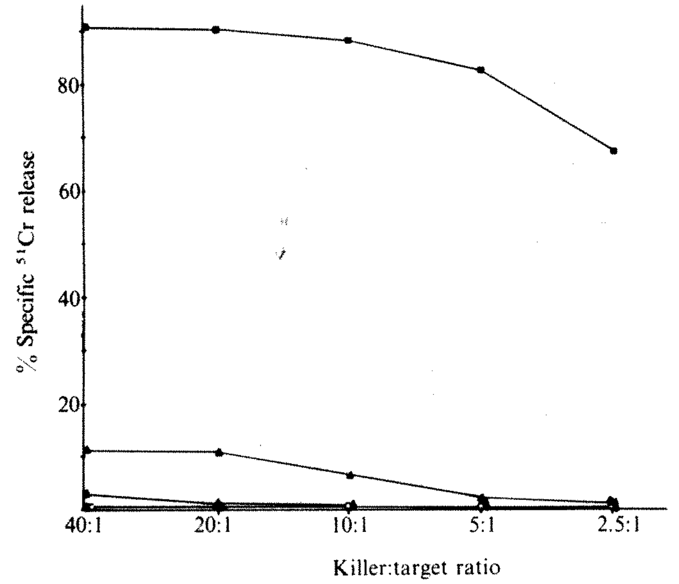

Fig. 1 Cell-mediated lysis of *Theileria*-transformed cell lines. Bovine peripheral blood lymphocytes were purified[9] from non-immunised animal 951 or from *Theileria*-immune animal 713 and cytotoxic lymphocytes were generated in MLC and assayed as previously described for the mouse[16], except that the stimulator cells were irradiated (5,000R from a caesium source), the MLCs were incubated for 6 days, and the cytotoxic cells were adjusted to 1×10^7 per ml. Animal 713 was immunised by infecting with *T. parva* sporozoites and treating with the compound 993C 11 days later. It was then injected at 2-month intervals with 1×10^9 cells of the autologous *Theileria*-transformed line 713 on three separate occasions. The *Theileria*-transformed cells were labelled with ^{51}Cr (ref. 17) and used as targets within 30 min of labelling. Background (medium) release was 9% for the LINE$_{713}$ and 10% for the LINE$_{951}$. The data shown are representative of data from nine independent experiments with effectors from PBL$_{713}$ and LINE$_{713}$ MLC combinations and four experiments using cells from PBL$_{951}$ and LINE$_{951}$ combinations.

Effector:

○ PBL$_{713}$ (directly out of animal) ⎫
△ PBL$_{713}$ × MEDIUM ⎬ On LINE$_{713}$ targets.
■ PBL$_{713}$ × LINE$_{713(R)}$ ⎭
● PBL$_{951}$ × LINE$_{951(R)}$ ⎫ On LINE$_{951}$ targets.
▲ PBL$_{713}$ × LINE$_{713(R)}$ ⎭

activity was also seen when effectors from PBL$_{A143}$ × LINE$_{A143.D7(R)}$ and from PBL$_{953}$ × LINE$_{953(R)}$ MLC combinations were used on homologous targets. The PBL$_{A143}$ were from a bovid which was infected with sporozoites and cured by treatment with tetracyclines and PBL$_{953}$ were from an animal which became naturally infected and was cured with menoctone. A low level of killing of allogeneic *Theileria*-transformed cell lines was observed with each of these effector populations. No killing was observed when effectors were from MLCs containing PBL from normal animals 951 (Fig. 1) or A149 (data not shown). It is likely that these PBL require an initial 'priming' in order to generate helper cells for cytotoxic cells or to generate cytotoxic cell precursors. In the generation of cytotoxic T lymphocytes in the murine system[14], proliferation of 'helper' or precursor lymphocytes occurs on initial exposure to antigen. It is possibly this type of proliferation that we measured in the primary MLRs. It follows that after secondary stimulation *in vitro*, as with PBL$_{713}$, PBL$_{A143}$ and PBL$_{953}$ which were taken from immune animals, enough 'helper' cells or cytotoxic cell precursors were present to allow differentiation of cytotoxic effectors.

Our results show that cytotoxic cells can be induced in PBL from *Theileria*-immune animals by co-culture with syngeneic *Theileria*-transformed cell lines. These cytotoxic cells kill *Theileria*-transformed cells and their generation may thus be used as a measure of immunity to the parasites. It is most likely that after challenge with *Theileria*, cytotoxic cells develop in both immune and non-immunised cattle. Why then do most non-immunised cattle die after between 18 and 24 days of infection? Our results support the widely held hypothesis[15] that it is simply due to outpacing of the immune response by growth of the parasite since once an animal has recovered from infection it is solidly immune. By biasing the immune system towards *Theileria*-specific cell-mediated immunity it should be possible to immunise cattle. Our results suggest that priming of the bovine immune system with allogeneic *Theileria*-transformed cell lines may be possible, that is, the priming may not be H-restricted. If such cell lines are attenuated so that they do not cause lethal infection they may allow sensitisation of the immune system so that a second exposure to antigen causes an effective cytotoxic response to *Theileria*-transformed lymphocytes.

This project was supported in part by the Ministry of Overseas Development. We thank C. G. D. Brown and G. K. Kanhai for 951 and 784 cell lines, T. Kurtti for the A143.D7 and A149 cell lines and Doris Churi for editorial assistance.

Antibiotic-induced muscle paralysis has frequently been found in both experimental animals and man with three distinct classes of antibiotic: (1) streptomycin and related aminoglycoside compounds, (2) polymyxins and (3) tetracyclines[1]. Recently lincomycin and its chemical congener, clindamycin, have been reported to produce muscle paralysis which has different characteristics from those seen with other classes of antibiotic[2–4]. Although closely related in chemical structure, lincomycin and clindamycin also seem to produce muscle paralysis by different mechanisms. Clindamycin is considered to exert a direct depressant action on muscle contractility whereas the action of lincomycin is considered to be primarily a depression of neuromuscular transmission. We report here that each of these antibiotics had a significant but different influence on endplate channel behaviour. Clindamycin increased the rate of miniature endplate current (m.e.p.c.) decay and reduced its voltage sensitivity without altering its exponential nature. Lincomycin split m.e.p.c. decay into an initial rapid phase followed by a prolonged phase.

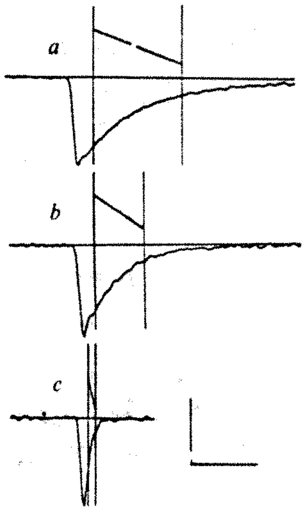

Fig. 1 The effect of clindamycin on m.e.p.c. decay is concentration dependent. Averaged m.e.p.cs (13–17 individual currents) obtained in a fibre voltage clamped at −120 mV in control Ringer (*a*) 2.12×10^{-5} M clindamycin (*b*) and 4.26×10^{-4} M clindamycin (*c*). Above each current record a portion of the decay is plotted semilogarithmically and fitted with a least-squares regression line to evaluate the decay time constant. The linearity of the plot indicates that m.e.p.cs decay as a single exponential with time. The decay time constants (ms) were: *a*, 3.41; *b*, 1.89; *c*, 0.298. Calibration bars: *a*, 5.4 nA, 3.5 ms; *b*, *c*, 2.7 nA, 3.5 ms.

Spontaneous m.e.p.cs were recorded in voltage-clamped twitch fibres of the costocutaneous muscle of garter snakes (*Thamnophis* sp.). Muscles were removed with a portion of the rib and scale on which they inserted and mounted in a small (4 ml) Plexiglass chamber filled with physiological solution of composition (mM): NaCl 159; KCl 2.15; $CaCl_2$ 2.0; $MgCl_2$ 4.2; HEPES 1.0, at *p*H 7.3–7.4. Experiments were carried out at room temperature (20–24 °C). All solutions contained 100 nM tetrodotoxin. The snake neuromuscular junction is well suited for these studies, for the endplate region is compact relative to the fibre space constant (1–4 mm)[5], enabling the voltage clamp to provide effective voltage control over the entire active synaptic area. With the muscle spread laterally, individual endplates can be easily visualised and voltage clamped with two microelectrodes as described previously[6]. M.e.p.cs were digitally recorded and analysed using a DEC PDP8E computer; those with the most rapid rate of rise (<1 ms) were selected for analysis. An average of 10–20 m.e.p.cs were recorded and averaged at each holding potential. Stock solutions of the antibiotics (clindamycin HCl, lincomycin HCl) were freshly prepared in the physiological solution. Drugs were added by replacing the bath volume three times with drug-containing solution. An equilibration period of at least 10 min elapsed before recording at each concentration. Averaged control m.e.p.cs could be fitted to the expression, $I(t) = I(0) \exp(-t/\tau)$, where $I(0)$ is the peak current, t is time after peak and τ is the decay time constant given by the semilogarithmic slope. At all voltages control m.e.p.cs decayed with a single exponential time course. The decay time constant was determined by confining the analysed portion to between 20 and 80% of the peak amplitude.

Clindamycin reduced the amplitude and shortened the time course of m.e.p.c. decay. The effects of clindamycin were concentration dependent in the range studied (2.12×10^{-5} M–4.26×10^{-4} M). Figure 1 shows the concentration dependence in a single fibre voltage clamped at −120 mV. Note that both in control records and records of the two concentrations of clindamycin the m.e.p.cs decayed as a single exponential with time. This was consistently observed at all voltages and concentrations of clindamycin. The dependence of the m.e.p.c. decay on clindamycin concentration is indicated by the amount of change in the semilogarithmic plot above each current record. In Fig. 1 τ was decreased 45% and 91% in clindamycin concentrations of 2.12×10^{-5} M and 4.26×10^{-4} M, respectively.

In normal physiological solution $\tau_{\text{m.e.p.c.}}$ is sensitive to changes in membrane potential[6–8]. The voltage dependence of $\tau_{\text{m.e.p.c.}}$ can be accurately described by the exponential function

$$\tau(V) = \tau(0)e^{-AV} \tag{1}$$

where $\tau(0)$ is the decay time constant at zero membrane potential, V is the membrane potential and A is the voltage coefficient of τ. In five control cells the average coefficient of voltage sensitivity, A (mV^{-1}), was 0.015 ± 0.001 (mean ± s.e.). This value is similar to that previously reported for snake twitch fibres[6]. The dependence of τ on voltage obtained in a single fibre for both control and two concentrations of clindamycin is illustrated in Fig. 2. Values of $\tau(0)$ and A calculated according to equation (1) were: control physiological solution: $\tau(0) = 0.783$ ms, $A = -0.0118\ \text{mV}^{-1}$; 2.12×10^{-5} M clindamycin: $\tau(0) = 0.775$ ms, $A = -0.0069\ \text{mV}^{-1}$; 4.26×10^{-5} M clindamycin: $\tau(0) = 0.521$, $A = +0.0033\ \text{mV}^{-1}$. In the presence of clindamycin there was a concentration-dependent reduction in the voltage sensitivity. With concentrations of clindamycin of 2.12×10^{-4} M or higher the voltage sensitivity was either abolished or reversed (as in Fig. 2). The shortening of m.e.p.c. decay and reduction in the voltage sensitivity of $\tau_{\text{m.e.p.c.}}$ produced by clindamycin were reversible on return to control physiological solution.

In marked contrast to the effects of clindamycin on m.e.p.c. decay lincomycin converted the decay of m.e.p.cs to a multiexponential function consisting of at least two distinct components, one more rapid and another slower than the decay of control m.e.p.cs. The effect of lincomycin on m.e.p.c. decay rates and amplitude was both voltage and concentration

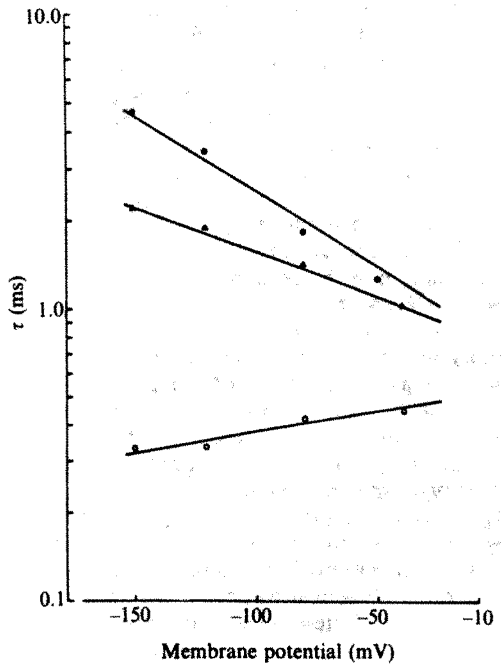

Fig. 2 The voltage dependence of τ is reduced by clindamycin. m.e.p.c. decay for both control and clindamycin depend exponentially on voltage over the range −40 mV to −150 mV. Control (●) and measurements in the presence of clindamycin, 2.12×10^{-5} M (▲) and 4.26×10^{-4} M (○), were fitted according to equation (1).

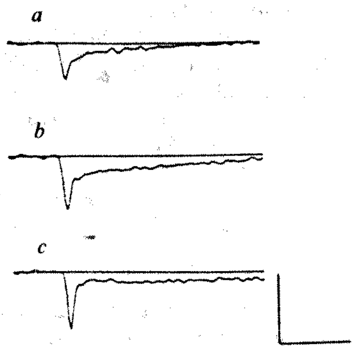

Fig. 3 The action of lincomycin on m.e.p.c. decay is voltage dependent. Averaged m.e.p.cs (13–20 individual currents) were recorded in a single fibre at −50 mV (*a*), −100 mV (*b*) and −150 mV (*c*). Lincomycin concentration was 4.43×10^{-4} M. Calibration bars: 2.7 nA, 3.5 ms.

dependent. Increasing the concentration of lincomycin above the threshold concentration (10^{-4} M) at a fixed voltage produced an increase in the relative size of the rapid initial decay and prolonged the time course of the terminal phase. Similarily, these phases varied with membrane potential at a constant lincomycin concentration. The voltage dependence of lincomycin action recorded in a single voltage-clamped fibre is shown in Fig. 3. The initial fast component of decay declined more quickly and comprised a larger portion of the total m.e.p.c. decay as the membrane was hyperpolarised. The slow component became greatly reduced in amplitude and decayed very slowly with hyperpolarisation. The time constants of decay for both phases were determined using a computerised least-squares exponential fitting program[9]. For the currents depicted in Fig. 3 the fast and slow decay time constants (ms) were, respectively, 0.30 and 3.56 at −50 mV, 0.17 and 6.78 at −100 mV, 0.17 and 20.8 at −150 mV.

The time constant of m.e.p.c. decay is well established as a measure of the mean open duration of endplate channels in frog twitch fibres[7]. A similar relationship has been reported for snake twitch fibres[6]. Alteration in the decay of both e.p.cs and m.e.p.cs have been reported for various drugs, including local anaesthetics[10–12] and belladonna alkaloids[13,14]. The results reported here for clindamycin are similar to those previously reported for atropine and the lignocaine derivative QX314 (refs 10, 11). In addition, the splitting of m.e.p.cs by lincomycin is qualitatively similar to results reported for scopolamine[13] and the lignocaine derivative QX222 (refs 10, 11). These similarities are consistent with an interaction of the antibiotics with the open state of the acetylcholine receptor–channel complex, creating a channel with little or no conductance[12,15].

Clindamycin differs from lincomycin in chemical structure by the presence of a chloride substituent in position 7. The present results indicate that this chemical modification, which greatly increases the lipid solubility, influences the characteristics of m.e.p.c. decay. Of particular importance is the finding that these agents modify channel behaviour in concentrations which might normally be present in plasma. We suggest that the interaction of antibiotics with the endplate receptor–channel complex might help to explain the differences in neuromuscular block obtained with these antibiotics and also improve our understanding of the mechanisms of antibiotic-induced paralysis.

Role of intracellular Ca^{2+} sequestration in β-adrenergic relaxation of a smooth muscle

Erich Mueller & C. van Breemen

Department of Pharmacology, University of Miami School of Medicine, Miami, Florida 33101

Various mechanisms have been proposed for β-adrenergically mediated relaxation of smooth muscle. All theories suggest the involvement of cyclic AMP as a second messenger: β-agonists stimulate adenylate cyclase which converts ATP to cyclic AMP[1] and protein kinase, activated by cyclic AMP, is then thought to catalyse a protein phosphorylation that leads to a reduction in free Ca^{2+}, thus effecting relaxation[1]. How this last step is accomplished is much debated, but the following possibilities are currently considered as the mechanisms responsible for cyclic AMP-induced reduction of cytoplasmic Ca^{2+}: activation of a Ca^{2+}-ATPase in the plasma and/or sarcoplasmic reticulum membranes which lowers cytoplasmic $[Ca^{2+}]$ in a direct manner or stimulation of $(Na^+$–$K^+)$ATPase in the cell membrane which may indirectly effect Ca^{2+} extrusion[2–8]. Among the hypotheses suggested, those of Ca^{2+} sequestration by the sarcoplasmic reticulum and of Ca^{2+} extrusion across the cell membrane are consistent with each other if it is assumed that both processes are effected by a cyclic AMP-sensitive Ca^{2+}-ATPase. However, quite a different mechanism is implied by involving the Na^+–K^+ pump and Na^+–Ca^{2+} exchange carrier. In this report, we present evidence that suggests intracellular Ca^{2+} sequestration is the mechanism involved.

Stopping the Na^+–K^+ pump with ouabain initiates a transient contraction in the taenia coli. The inhibited pump is unlikely to be stimulated by β-adrenergic activation, so this system provides the opportunity to test whether $(Na^+$–$K^+)$ATPase is required in cyclic AMP-mediated relaxation. The possible involvement of a Na^+–Ca^{2+} exchange carrier can be tested by studying relaxation of a high K^+-induced contracture in the absence of Na^+. In Fig. 1*a*, β-stimulation, phosphodiesterase inhibition and the application of 8-bromo-cyclic AMP can be seen to relax the ouabain-induced contraction. Each of these has been postulated to relax smooth muscle by increasing protein kinase activity through a rise in cytoplasmic cyclic AMP. In each case, the muscle relaxed below the resting tension. The delayed response of 8-bromo-cyclic AMP may be due to its slower diffusion into the cell. It is unlikely that these results are due to incomplete blockade of the Na^+–K^+ pump because they were duplicated with a contraction initiated by 10^{-4} M ouabain in the absence of external K^+.

Each of these agents also relaxed 145 mM K^+/0 Na^+ contractures (Fig. 1*b*), although the isoprenaline relaxation was transient. The decline in tissue Na^+ was measured in the 145 mM K^+/0 Na^+ solution. After exposure for 0, 2, 5 and 10 min, respective tissue Na^+ concentrations were 60 ± 3, 14.4 ± 1.2, 4.9 ± 0.9 and 0 mM Na^+ per kg taenia coli. At the point

0028–0836/79/430682—02$01.00

when relaxing agents were added (3 min), not all the Na$^+$ had left the cells. However, depletion of extracellular Na$^+$ reversed its gradient and would thus be unable to effect Ca^{2+} extrusion as postulated by Scheid *et al.*[7]. Identical relaxations were also obtained after exposure to the 145 mM K$^+$/0 Na$^+$ solution for 30 min, when all Na$^+$ had left the tissue.

Net Ca^{2+} fluxes (Fig. 2*a*, *b*) were measured during phosphodiesterase inhibition, as R0-20-1724 (a phosphodiesterase inhibitor; Roche) induced the most rapid tension reductions (see Fig. 1*b*). Neither ouabain nor the subsequent addition of R0-20-1724 induced significant changes in total exchangeable tissue Ca^{2+} (Fig. 2*a*). These results indicate that Ca^{2+} is released intracellularly during ouabain contraction and sequestered by an intracellular store during phosphodiesterase-induced relaxation.

The high-K$^+$ contraction (Fig. 2*b*) is characterised by an initial phasic portion that has been postulated to be at least partly mediated by intracellular Ca^{2+} release[9,10]. This is followed by a tonic contracture maintained by a net influx of Ca^{2+}. Again, however, no change in Ca^{2+} is observed with relaxation.

Relaxation by all three procedures, which raise cellular cyclic AMP, has been shown to occur when the Na$^+$–K$^+$ pump is inoperative or when there is no Na$^+$ in the medium or the cells. These results indicate that an increased inward-directed Na$^+$ gradient, whether or not the result of Na$^+$–K$^+$ pump stimulation, is not essential for β-adrenergic relaxation.

A recent study[7] has reported that Na$^+$–K$^+$ pump inhibition decreased the relaxing effect of isoprenaline or carbachol contractions. This could also be explained by superimposition of the ouabain contraction on the contractile effect of the carbachol.

The data presented here support the hypothesis that cyclic AMP-mediated relaxation is caused by Ca^{2+} sequestration[4,11,12]. The evidence also suggests that contraction is at least partially regulated by intracellular Ca^{2+} stores. Although the ouabain-induced myofilament activation seems to be controlled primarily by these stores, the high K$^+$ depolarisation produces activation that depends largely on extracellular Ca^{2+}. Finally, note should be made of recent evidence[13] that cyclic AMP may effect relaxation by inactivating myosin light chain kinase, thus reducing tension at the myofilament level. The data presented here are equally consistent with this model and that of stimulated sarcoplasmic reticulum Ca^{2+}-ATPase.

Either or both of these mechanisms may be operative in taenia coli during β-mediated relaxation but our evidence rules out net efflux of Ca^{2+}, specifically that by a Na$^+$–Ca^{2+} exchange carrier.

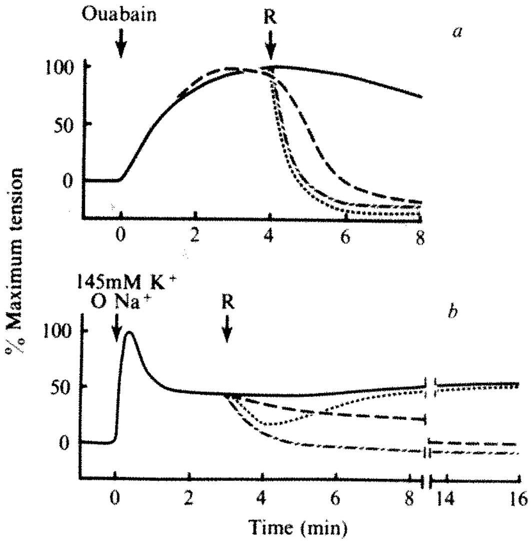

Fig. 1 *a*, Relaxation of ouabain-induced contractions. Tension of pieces ot taenia coli ~1 cm long was measured isometrically in physiological saline solution (PSS) (in mM; NaCl, 140; KCl, 5; CaCl$_2$, 1.5; MgCl$_2$, 1; dextrose, 10; HEPES, 5; *p*H 7.2, oxygenated) to which atropine (10^{-6} M) and phentolamine (10^{-5} M) had been added. These blocked any possible muscarinic or α-adrenergic effects, respectively. Muscles were contracted with 2×10^{-5} M ouabain. Four minutes later the relaxants were added: 5×10^{-4} M 8-bromo-cAMP (– – –), 10^{-3} M R0-20-1724 (– · –) or 10^{-5} M isoprenaline (· · · · ·). *b*, Relaxation of high K$^+$-induced contractions. Procedure as for *a* except that taenia were contracted in PSS in which all Na$^+$ was replaced by K$^+$. Relaxants were added 3 min after t_0.

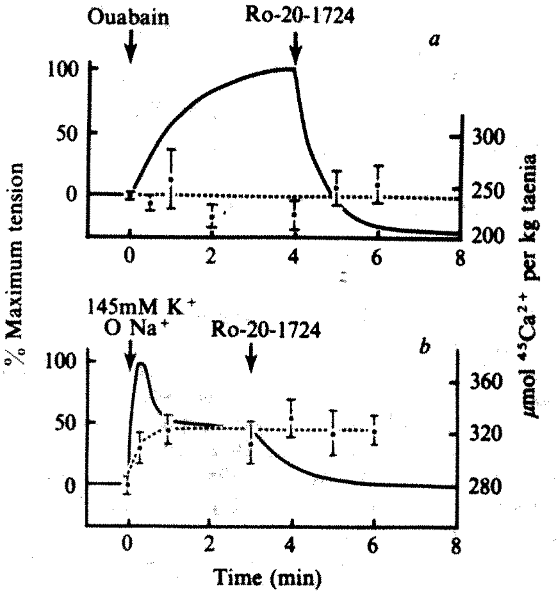

Fig. 2 *a*, Net Ca^{2+} content of taenia coli during ouabain-induced contracture and subsequent R0-20-1724-induced relaxation. Tissues were incubated in ^{45}Ca-labelled PSS for 90 min to label tissue Ca^{2+}; they were then sequentially exposed to the contracting and relaxing solutions as in Fig. 1 which were labelled at the same specific radioactivity. Labelled Ca^{2+} was measured in a scintillation counter after removal of extracellular Ca^{2+} in ice-cold PSS (0 Ca + 2 mM EGTA) for 45 min. Points represent mean ± s.e. for four determinations. *b*, Net Ca^{2+} during high K$^+$-induced contraction and subsequent relaxation by R0-20-1724. Tension tracing from *a*. Tissues were placed in 145 mM K$^+$–0 Na$^+$ HEPES buffer and R0-20-1724 (1 mM) was added 3 min later. ^{45}Ca measurements were made as in *a*.

We thank Dr Marcos Hardy for the 8-bromo-cAMP used and Pauline Zera for technical assistance. This work was supported by American Heart Association grant 781124 and NIH grant HL-07188.

Extracellular but not intracellular application of peptide hormones activates pancreatic acinar cells

H. G. Philpott & O. H. Petersen

Department of Physiology, University of Dundee, Dundee, UK

Peptide hormones, like neurotransmitters, are traditionally thought to activate cells by interacting with receptor sites accessible only from the extracellular space[1-3]. However, there is no available evidence that establishes whether intracellular injections of peptide secretagogues can or cannot initiate cell activation. In view of recent demonstrations that peptide hormones can penetrate the intracellular space in some tissues[1,4] and the reports that intracellular injections of the neurotransmitter, dopamine, into acinar cells of cockroach salivary gland cause stimulation[5] it seems of fundamental importance to test directly whether introduction of peptide secretagogues inside acinar cells of mammalian exocrine tissue can induce cell activation without first interacting with the outer surface of the external cell membrane. The data presented here show that injections of the secretagogue peptides caerulein and bombesin-nonapeptide (bombesin-NP) into pancreatic acinar cells fail to evoke the characteristic potential and conductance changes that are observed following extracellular applications of these peptides.

The experiments were carried out on segments of mouse pancreas superfused with a physiological saline solution equilibrated with 95% O_2, 5% CO_2 at 37 °C. Membrane potentials and resistance from two electrically coupled acinar cells were measured with two microelectrodes and application of caerulein and bombesin-NP from microelectrodes using ionophoresis was carried out as previously described[6,7]. One intracellular microelectrode was filled with 3 M KCl and the other with 30 μM caeruletide (diethylamine salt) dissolved in 0.9% NaCl (*p*H 4) or 100 μM bombesin-nonapeptide hydrochloride in 0.9% NaCl (*p*H 4) (Farmitalia). The extracellular micropipette was filled with the same peptide solution as that used for the intracellular electrode.

The effects of caerulein ionophoresis are shown in Fig. 1. Extracellular application evoked the characteristic cell depolarisation and reduction in input resistance from the recording cell. In contrast, after the caerulein electrode had been inserted into a communicating acinar cell, intracellular ionophoresis had no effect on the electrical properties of either of the two impaled cells, while extracellular caerulein application from another electrode still evoked the characteristic response. After withdrawal of the tip of the intracellular caerulein electrode to the extracellular space, the electrode was still able to deliver caerulein and thereby effect the usual electrical response from the cell that remained impaled with the KCl electrode. From the 32 intracellular ejections of caerulein that were carried out on 14 acinar cells in pancreatic tissue from five mice, no response from the cells was obtained. Of special interest in Fig. 1 is the effect of spontaneous leakage of caerulein from the caerulein electrode causing depolarisation of the recording cell[7]. This was abolished once the caerulein electrode had been impaled into an acinar cell, allowing both cells to repolarise.

Figure 2 demonstrates that intracellular ionophoresis of bombesin-NP has no effect on the electrical properties of the acinar cell membrane in conditions where extracellular bombesin-NP applications evoked clear membrane resistance and potential changes. Application of a negative current through an extracellular bombesin electrode does not release bombesin or cause stimulation, but application of a positive ejection current does achieve this. The membrane depolarisation effect observed after applying a negative, hyperpolarising

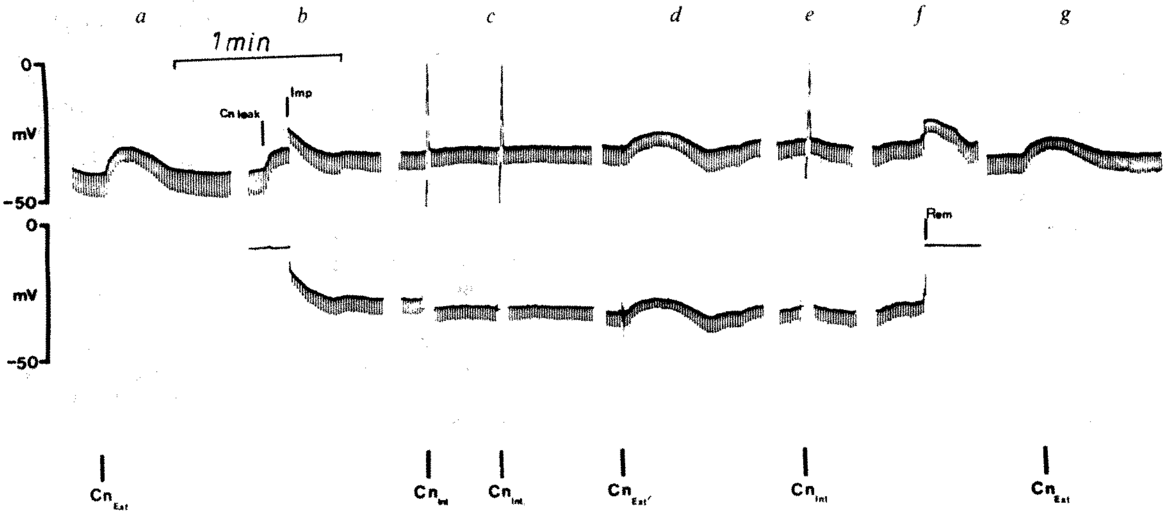

Fig. 1 Effect of extracellular and intracellular ejection of caerulein, applied to pancreatic acinar cells, on the membrane potential and input resistance. Panels *a*–*g* are consecutive traces. In *a* the cell membrane potential was measured from an intracellular KCl microelectrode through which rectangular hyperpolarising current pulses (2×10^{-9} A, 100 ms duration) were repeatedly injected to obtain cell input resistance. At $\mathrm{Cn_{Ext}}$ a positive ionophoretic current (100 nA, 500 ms duration) was applied to a caerulein-containing electrode (Cn-electrode) whose tip was positioned near to the surface of the impaled cell. In *b* the Cn-electrode, previously used for extracellular ionophoresis, was impaled at 'Imp' into an acinar cell that was in electrical communication with the cell impaled with the KCl electrode. 'Cn-leak' indicates the depolarisation of the recording cell arising from caerulein leakage from the approaching tip of the caerulein electrode, before impalement. In *c* and *e* at places marked '$\mathrm{Cn_{Int}}$' intracellular ionophoresis of caerulein was carried out. At *d* a second caerulein electrode was positioned near to the two indwelling electrodes and used for extracellular caerulein ionophoresis at '$\mathrm{Cn_{Ext'}}$'. In *f* the intracellular caerulein electrode was removed from the acinar cell at the place marked 'Rem'. In *g* after time was allowed for the first impaled cell to recover from disturbance caused by removal of the caerulein electrode, the same caerulein electrode was then used for extracellular ionophoresis at '$\mathrm{Cn_{Ext}}$'. A positive injection current of 100 nA lasting 500 ms was used throughout the experiment for caerulein ionophoresis. Time intervals between panels *a* and *b*, 20 s; *b* and *c*, 40 s; *c* and *d*, 6 min; *d* and *e*, 60 s; *f* and *g*, 20 min.

0028-0836/79/430684—03$01.00

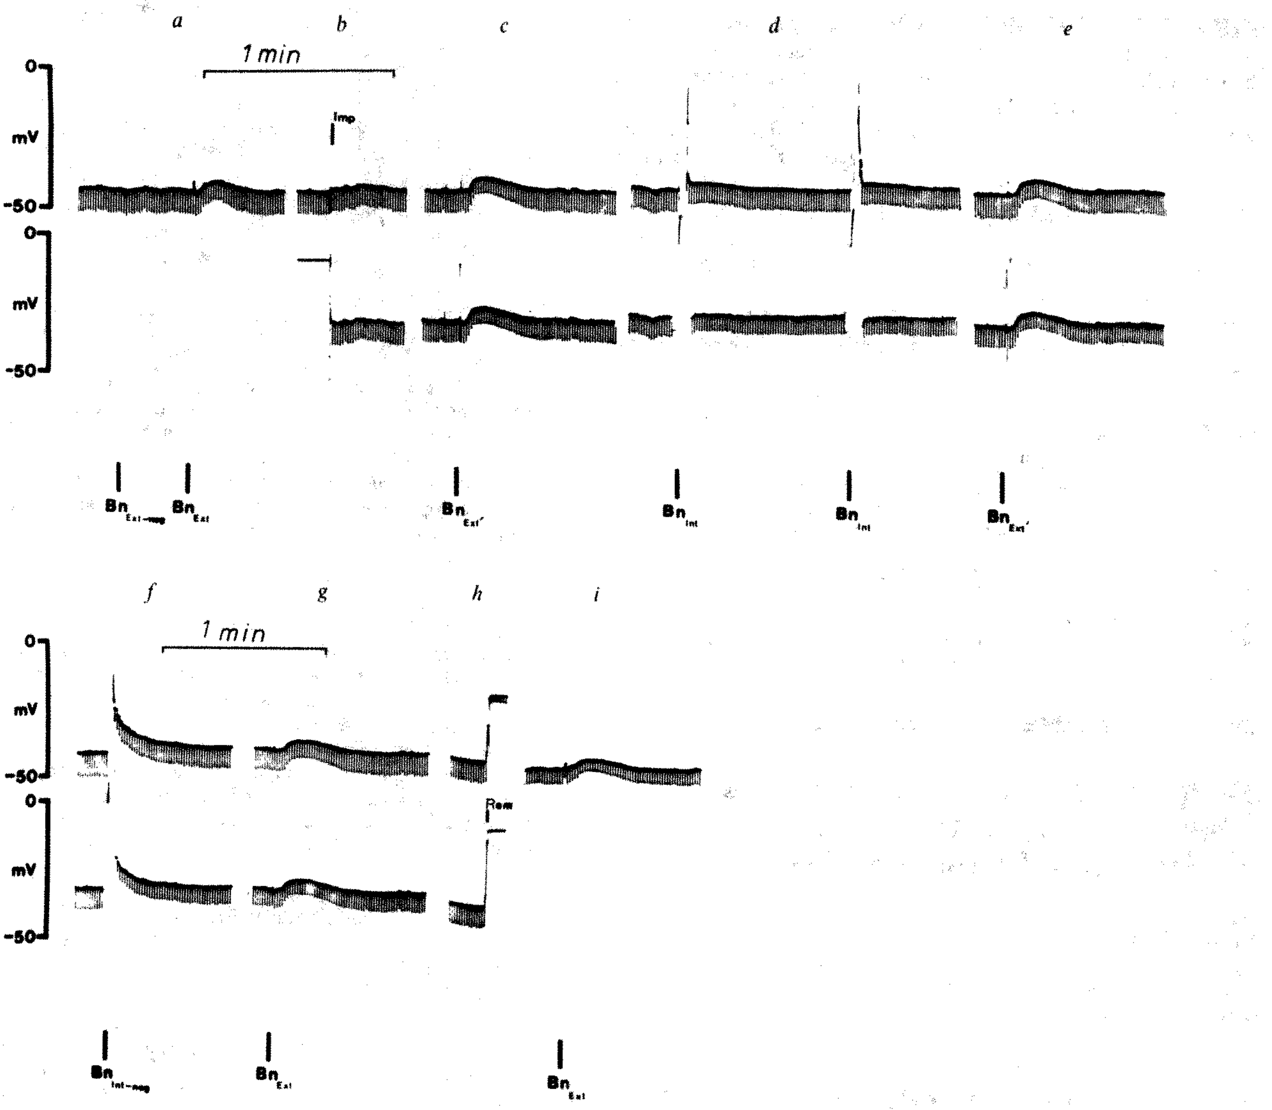

Fig. 2 Effect of extra- and intracellular ionophoresis of bombesin on pancreatic acinar cells. At 'Bn$_{\text{Ext-neg}}$', a negative ejection current was applied to a bombesin-containing electrode, near to the surface of the impaled cell. A second but positive current was then applied at 'Bn$_{\text{Ext}}$'. In *b* the Bn-electrode was inserted into an acinar cell coupled with the first recording cell. In *c* and *e* another extracellular bombesin electrode was placed near to the coupled cells and at 'Bn$_{\text{Ext'}}$' an ionophoretic current was then applied. In *d* at places marked 'Bn$_{\text{Int}}$' intracellular ionophoresis of bombesin was carried out. In *f* at 'Bn$_{\text{Int-neg}}$' the effects of passing a hyperpolarising current through the intracellular bombesin electrode are shown. *h*, Bn electrode removed at 'Rem'. *i*, At 'Bn$_{\text{Ext}}$' bombesin was ionophoresed extracellularly on to the remaining impaled cell using the previously indwelling Bn electrode. Throughout the experiment an ejection current of 400 nA lasting 500 ms was used for bombesin-NP ionophoresis. Time intervals between panels *a* and *b*, 7 min; *b* and *c*, 2 min; *c* and *d*, 7 min; *d* and *e*, 3 min; *e* and *f*, 7 min; *f* and *g*, 50 s; *g* and *h*, 13 min; *h* and *i*, 7 min.

current through the intracellular bombesin electrode (Fig. 2*f*) is not, therefore, due to bombesin-induced effects, but results from breakdown in the dielectric properties of the membrane, usually associated with intracellular injection of large hyperpolarising currents[8]. Of the 37 intracellular injections of bombesin into 11 acinar cells obtained from four mice, 30 showed no effect on membrane potential and resistance, 5 results showed a small effect on membrane resistance but no depolarisation, and 2 results gave a small but definite depolarisation and resistance reduction when compared to the bombesin-evoked responses obtained with extracellular application using the same electrode. The exceptional intracellular bombesin depolarising effects were only observed in cells where the resting membrane potentials were extremely low (< -23 mV). These effects are likely to have arisen from seepage of bombesin out of the acinar cell due to incomplete resealing of the cell membrane around the impaling electrode. Evidence for the leakage of intracellularly applied calcium out of injected cells with very low membrane potentials, has previously been given[9].

The experiments presented here are the first to monitor the electrical response of target cells during intracellular application of peptide hormones. The results provide evidence for the hypothesis that peptides like caerulein and bombesin, as also found for the neurotransmitter acetylcholine[2,3], attach to receptors on the outer surface of cell membranes as a prerequisite to stimulation. Specific binding of radiolabelled bombesin to the plasma membrane of pancreatic acinar cells has recently been demonstrated[10].

There seems to be a discrepancy between the results reported here and the study of House *et al.*[5] showing potential changes in cockroach salivary gland cells, with intracellular dopamine application. The apparent intracellular dopamine effects, however, as the authors suggested[5], may have been due to leakage of injected transmitter into the extracellular compartment.

Having established that, in order to achieve cell activation, the pancreatic acinar secretagogues must first attach to receptors on the extracellular side of the plasma membrane, there seems to be a need for an intracellular mediator. Intracellular Ca^{2+} application has been shown to mimic the electrical effects induced by outside application of pancreatic secretagogues[8,9] and therefore seems the most likely intracellular messenger. An alternative but more complicated theory is that a further mediation step may occur and take the form of a peptide hormone/receptor complex undergoing cell internalisation. To test this possibility studies should be carried out in the pancreas.

We thank Dr R. de Castiglione (Farmitalia, Milan) for providing caerulein and bombesin nonapeptide, and the MRC for grant support.

Morphine-induced striatal dopamine efflux depends on the activity of nigrostriatal dopamine neurones

P. Moleman & J. Bruinvels

Department of Pharmacology, Faculty of Medicine,
Erasmus University, PO Box 1738, Rotterdam, The Netherlands

It is clear that morphine markedly increases the turnover of dopamine (DA) in the rat striatum[1–3], although the nature of this increase remains obscure. The early suggestion, that morphine may block postsynaptic DA receptors in a similar manner to haloperidol[4], has since been refuted[5,6]. The effect of morphine on dopaminergic neurones seems to be presynaptic, but whether it stimulates[7,8] or inhibits[2,5] the functional activity of the dopaminergic neurones is unclear. We recently reported that morphine seems to have no effect on the functional activity of the nigrostriatal dopaminergic neurones, using the decline in DA after administration of α-methyl-*p*-tyrosine (αMT) as a measure of DA efflux[9,10]. However, the substantia nigra and striatum are extremely rich in opiate receptors[11,12], and a considerable number of the striatal opiate receptors seem to be localised on dopaminergic nerve endings[13]; it would therefore be rather surprising if stimulation of these receptors by morphine did not alter the functional activity of the nigrostriatal dopaminergic neurones. To investigate this apparent discrepancy, we analysed the effect of morphine on DA efflux in conditions of altered impulse flow in the nigrostriatal dopaminergic neurones. The present results show that the administration of morphine results in increased efflux of DA from neurones with a lowered firing rate, but not from neurones with a normal or increased firing rate. Thus, morphine may be a modulator of the nigrostriatal dopaminergic neurones in that it counteracts decreasing dopaminergic activity, but has no effect when the activity is normal or increased.

Male albino Wistar rats were treated with αMT methylester.HCl (254 mg per kg, intraperitoneally (i.p.)) half an hour before further treatment, which was aimed at altering the activity of the nigrostriatal neurones. These various treatments consisted of unilateral electrolytic lesion of the substantia nigra, apomorphine or haloperidol administration. Morphine (20 mg per kg, i.p.) was administered 17 min after lesion or together with apomorphine or haloperidol. Two hours after morphine administration the rats were decapitated and the striata were dissected out as described by Gispen *et al.*[14]; DA was assayed fluorimetrically as reported earlier[10].

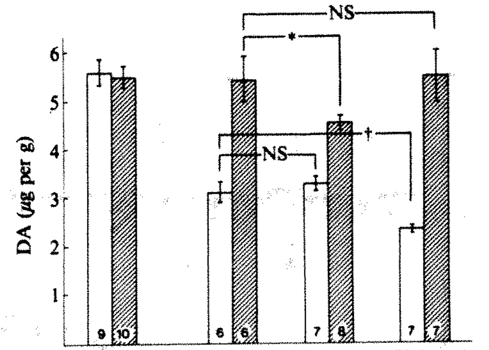

Fig. 1 Effect of morphine and haloperidol on the loss of striatal dopamine after αMT treatment in rats with unilateral lesion of the mesencephalic dopaminergic cell bodies. Male albino Wistar rats weighing 195–205 g were treated according to the time schedule given below. Unilateral electrolytic lesions of the right mesencephalic dopaminergic cell bodies were made stereotaxically by means of an iron electrode, 1 mm thick, coated with epoxy varnish except for 0.5 mm at the tip. A current of 2 mA was passed through the electrode for 3 min. The coordinates of the electrode were 6.6 mm caudal, 2.0 mm lateral and 7.7 mm ventral from the bregma. Midbrains were removed at the end of the experiment, fixed in formalin and examined histologically for electrode placements. All rats were injected with αMT 25 min before the lesion was made. Seventeen minutes after lesioning, the control rats were decapitated, while the other rats received morphine, haloperidol or saline injection. Most animals, at the moment of drug injection, had recovered from the light ether anaesthesia applied before lesioning. Rats were decapitated 2 h after injection of morphine, haloperidol or saline. Striata were dissected out according to Gispen *et al.*[14] and DA was extracted and assayed as reported elsewhere[10].

Time schedule of treatments (min)

Treatment group	0	25	42	162
Control	αMT	Lesion	Decapitation	–
Saline	αMT	Lesion	Saline	Decapitation
Morphine	αMT	Lesion	Morphine	Decapitation
Haloperidol	αMT	Lesion	Haloperidol	Decapitation

αMT: 254 mg per kg; morphine: 20 mg per kg; haloperidol: 1 mg per kg. All injections were made i.p. in a volume of 5 ml per kg. Drugs were dissolved in 0.9% NaCl. Statistics: Duncan's new multiple range test[22]. Values represent mean ± s.e.m.; number of observations are indicated at the base of the columns. Mean wet tissue weight: 46.1 mg ± 5.3. □, Control; ▨, lesion. * $P < 0.05$; † $P < 0.01$; NS, not significant.

Figure 1 shows that lesion of the mesencephalic dopaminergic cell bodies entirely prevented the loss of DA from the ipsilateral striatum. Injection of morphine resulted in loss of DA on the lesioned side but not on the side contralateral to the lesion, when compared with saline-treated rats. Haloperidol injection, on the other hand, resulted in increased loss of DA on the unlesioned side, but was without effect on the lesioned side. Thus, morphine seems to produce an efflux of DA from inactive neurones in the striatum but not from normally firing neurones. As the opposite is true for haloperidol, we conclude that the observed effect of morphine is not mediated by blockade of the DA receptors, which are blocked by haloperidol. In the nucleus accumbens similar effects of morphine and haloperidol were observed (unpublished results).

We then evaluated the effect of morphine on the loss of DA in rats pretreated with apomorphine or haloperidol. Apomorphine reduces and haloperidol increases the firing rate of the nigral

0028–0836/79/430686—02$01.00

DA neurones[15]. Treatment of the rats with apomorphine alone resulted in a reduction of ~50% in the loss of DA. In these apomorphine-treated rats, as in lesioned rats, administration of morphine resulted in increased DA loss. When the loss of DA was increased, however, by the administration of haloperidol, morphine had no effect (Table 1). Therefore, morphine administration apparently results in the efflux of DA in the striatum as a function of the impulse flow.

Table 2 shows that the effect of morphine was most pronounced when the impulse flow was entirely abolished, that it was less pronounced, but still significant, when the impulse flow was reduced by 50%, and that it was virtually absent at normal or increased impulse flow.

The present experiments allow conclusions to be drawn on the effect of morphine on DA release, if one assumes that the loss of DA after αMT treatment reflects DA release. During the first 30 min after αMT administration DA biosynthesis is not completely inhibited[9] and DA-releasing metabolites of αMT may be formed[16]. This time period is not suitable for studying DA release, therefore, but between 0.5 and 2.5 h after αMT administration the loss of DA seems to be a reliable parameter for functional DA release[17]. However, drug-induced alterations in the loss of DA could result from intraneuronal events apart from functional DA release. It has been suggested that morphine increases the intraneuronal metabolism of DA by displacing DA from storage sites to sites of metabolism[2]. However, it is unlikely that the present results could be explained by such a mechanism. Although morphine administration to apomorphine-treated rats resulted in increased loss of DA (Table 1), we have shown that in the same experimental conditions morphine has no effect on the concentrations of the DA metabolites dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (unpublished results). Additionally, DiChiara *et al.*[18] have shown that in mice not pretreated with αMT, the rise in DOPAC concentrations observed after morphine administration is entirely abolished in apomorphine-treated animals.

Male Wistar rats weighing 100–135 g were treated according to the time schedule given in *c*. Separate experiments were carried out with apomorphine (*a*), 4 mg per kg as HCl Salt, and haloperidol (*b*), 3 mg per kg. All drugs were dissolved in 0.9% NaCl. In the apomorphine experiment 0.2 mg ml^{-1} ascorbic acid was added to this. Stastistics: Student's *t*-test. Striata of one rat weighed 105 ± 8.3 mg ($n = 29$) in *a* and 101 ± 8.4 mg ($n = 34$) in *b* (mean ± s.d.). For other experimental details see Fig. 1 legend.

* Mean dopamine concentrations ± s.e.m., number of experiments in parentheses.

† Values represent mean dopamine concentrations ± s.e.m., expressed as % of control values in untreated rats. Dopamine concentrations in untreated rats (100%): *a*, 4.51 ± 0.17 μg per g ($n = 3$); *b*, 6.61 ± 0.25 μg per g ($n = 4$).

‡ Different from the appropriate saline group ($P < 0.001$).

Table 2 Effect of morphine on dopamine efflux in the striatum as a function of the activity of striatal dopaminergic neurones

Treatment to alter dopaminergic activity	Rate of dopamine loss Saline	Rate of dopamine loss Morphine	Effect of morphine (morphine – saline)
Lesion	4 ± 14%	33 ± 9%	+29%*
Apomorphine	48 ± 10%	68 ± 7%	+20%*
None	100 ± 9%	105 ± 11%	+5%
Haloperidol	162 ± 10%	162 ± 9%	0%

Rate constants of dopamine loss were calculated from the data presented in Fig. 1 and Table 1. The rate constants obtained from rats not treated to alter dopaminergic activity and not treated with morphine was set at 100%. The respective 100% values were: lesion experiment: $k = 0.292 \pm 0.0394\ h^{-1}$; apomorphine experiment: $k = 0.310 \pm 0.0291\ h^{-1}$; haloperidol experiment: $k = 0.323 \pm 0.0184\ h^{-1}$. The rate of dopamine loss in the experimental groups was calculated as a percentage of the above control values.

* Significant difference, see Fig. 1 and Table 1.

We conclude, therefore, from the present experiments, that administration of morphine results in increased dopamine release in the rat striatum, when the activity of the nigrostriatal neurones is decreased. As the administration of morphine resulted in release of dopamine in the striatum after lesion of mesencephalic cell bodies (Fig. 1), this effect does not seem to be mediated by the substantia nigra. It seems more likely, therefore, that morphine exerts its releasing effects by a direct action on the dopaminergic axons, perhaps by means of presynaptic opiate receptors on striatal dopaminergic neurones[13]. Whether the reported stimulation of dopaminergic neurotransmission by morphine via the substantia nigra[8,19] has an underlying mechanism similar to the effect reported here, remains to be established. The similarity in the effects of morphine and endorphins on striatal dopaminergic systems[20,21] suggests that one function of the endogenous opioid systems may be to counteract decreases in the activity of the nigrostriatal dopaminergic system.

We thank Dr C. F. M. van Valkenburg and Mrs A. Petri-Bot for their hospitality and assistance in the lesion experiment, Mr C. D. Bor and Mr N. G. O. v.d. Sloot for the drawing, Mrs Y. Tjoa-Lie for technical assistance, Mrs E. Hillen and Miss J. Zaanen for typing, Dr M. Parnham for correction of the manuscript and Janssen Pharmaceutics for haloperidol. This work was supported by grants from the Netherlands Foundation for Medical Research and from the Dutch Government Project: Beleidsruimte Hersenen en Gedrag.

Bethesda, Maryland 20205

The benzodiazepines are potent anticonvulsants for a wide variety of experimental and clinical seizure disorders[1,2]. The demonstration of saturable, high-affinity and stereospecific binding sites for the benzodiazepines in the mammalian central nervous system suggests the presence of pharmacological receptors mediating the anticonvulsant properties of these compounds[3,4]. The good correlation between the anticonvulsant potencies of a series of benzodiazepines and their ability to inhibit ^{3}H-diazepam binding *in vitro* further supports this hypothesis[3,4], but evidence for a direct interaction between benzodiazepines and their receptors, and a subsequent inhibition of seizure activity (or elevation of seizure threshold) is lacking[5]. Recent reports from our laboratory[6] and others[7] have demonstrated the feasibility of labelling benzodiazepine receptors *in vivo* following parental administration of tritiated benzodiazepine. This technique permits one to study the relationship between the anticonvulsant activity of the benzodiazepines *in vivo* and the number of 'drug-occupied' receptors *in vitro*. We now report that there is an excellent correlation between benzodiazepine receptor occupancy by diazepam and protection against pentylenetetrazol-induced seizures. Furthermore, these results demonstrate that only a small fraction of benzodiazepine receptors need be occupied to produce a complete anticonvulsant effect.

As previous studies have shown that the anticonvulsant activity of a single dose of diazepam decreases with time[5], groups of 20 male –C3H/HEN mice (16–21 g) were injected with diazepam (4 mg per kg, intraperitioneally (i.p.), Hoffman-LaRoche) and the number of 'drug-occupied' benzodiazepine receptors was determined simultaneously with its anticonvulsant effects during a 72-h period. At each time point examined, half of the mice in each group were killed and both the apparent number of benzodiazepine receptors occupied by diazepam and the total concentration of benzodiazepine in forebrain[8] were determined. The remaining mice were challenged with pentylenetetrazol (80 mg per i.p., K and K Laboratories) to determine the per cent protected against seizures. Pentylenetetrazol-treated mice were counted as having had a seizure only if generalised tonic–clonic movements were observed within 15 min of injection. This dose of pentylenetetrazol produced seizures in >95% of vehicle-treated control mice.

In confirmation of previous reports[5], the number of diazepam-treated mice having seizures in each group increased as a function of time following drug administration. Figure 1 shows the duration of the anticonvulsant effect following a single dose of diazepam. Greater than 90% of the mice were protected against seizures during the first 12 h after diazepam administration, and a significant protection was evident for as long as 48 h following treatment. However, at 60 and 72 h post-injection, all the mice exhibited seizure activity when challenged with pentylenetetrazol (Fig. 1 and unpublished observations).

The concentration of pharmacologically active 'non-membrane'-bound benzodiazepine in the brain decreased rapidly and was undetectable 24 h after diazepam administration, despite a significant anticonvulsant effect for an additional 24 h (Fig. 1). In contrast to the brain concentration of 'free' benzodiazepine, the number of benzodiazepine receptors occupied by diazepam (or its pharmacologically active metabolite, desmethyldiazepam) decreased slowly over time (Fig. 1). An excellent correlation ($r = 0.98$, $P<0.01$) was observed between the number of drug-occupied receptors and protection against pentylenetetrazol-induced seizures (Fig. 1, inset). Occupation of only a small fraction (<30%) of the total number of forebrain benzodiazepine receptors was sufficient to elicit a full anticonvulsant effect.

To distinguish between drug-occupied receptors and receptor desensitisation which could occur due to prior drug–receptor interaction, it was necessary to demonstrate the presence of receptor-bound benzodiazepine in the diazepam-treated mice. As incubation of the benzodiazepine–receptor complex at 37 °C results in a rapid dissociation of drug from receptor[9], crude synaptosomal membranes from diazepam-treated and vehicle-treated mice were incubated at 37 °C for 60 min followed by centrifugation at room temperature (12,000*g* for 15 min). The

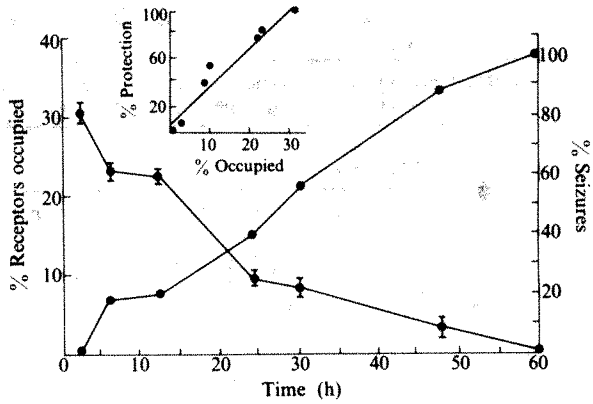

Fig. 1 Correlation between receptor occupation and anticonvulsant activity of diazepam. Mice were injected at time zero with diazepam (4 mg per kg, i.p.) and the number of drug-occupied benzodiazepine receptors was correlated with its anticonvulsant activity over the next 60 h. To determine the number of drug-occupied benzodiazepine receptors, mice were killed by decapitation and the crude synaptosomal fraction of forebrain (whole brain minus cerebellum and brainstem) was prepared by differential centrifugation[3]. The final synaptosomal pellet (P_2) was resuspended in 40 volumes of ice-cold Tris-HCl buffer (0.05 M, *p*H 7.4) to a final protein concentration of ~1 mg ml^{-1}. The corresponding supernatant (S_2) was frozen and stored at −20 °C for determining the free (unbound) concentration of benzodiazepine in brain[8]. Benzodiazepine receptors were measured in the resuspended P_2 fraction by modification of previously described methods[3]. The per cent of receptors occupied by benzodiazepine in synaptosomal membranes was determined by the formula: % occupied $= [(R_c - R_d)/B_{max}]100$, where $R_c = {}^3$H-diazepam bound in vehicle-treated mice, $R_d = {}^3$H-diazepam bound in diazepam-treated mice and B_{max} = maximum number of binding sites in vehicle-treated mice. The maximum number of binding sites in synaptosomal membranes from vehicle-treated mice was estimated by Scatchard analysis to be 1,213 fmol ^{3}H-diazepam bound per mg protein. R_c and R_d were determined in the presence of 4.4 nM ^{3}H-diazepam. At this concentration of ^{3}H-diazepam, $R_c = 653 \pm 10$ fmol ^{3}H-diazepam bound per mg protein ($n = 18$). The concentration of free or non-membrane-bound benzodiazepine was measured in the brain supernatants (S_2) using a radioreceptor assay[8].

0028-0836/79/430688—02$01.00

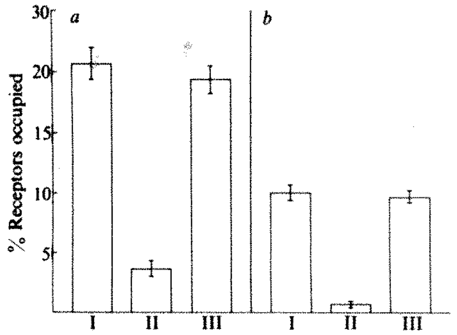

Fig. 2 Effects of *in vitro* incubation on receptor occupancy by benzodiazepines. Mice were injected with diazepam (4 mg per kg, i.p.) and synaptosomal membranes prepared 12 (*a*) or 24 (*b*) h later. Drug-occupied benzodiazepine receptors were determined as described in Fig. 1 legend. Group 1: % receptor(s) occupied by benzodiazepines. Group II: % receptors occupied following incubation of membranes from group I (37 °C for 60 min), centrifugation (12,000*g* for 15 min) and reconstitution with supernatant from vehicle-treated mice. Group III: % receptor(s) occupied in membranes of vehicle-treated mice reconstituted with supernatant obtained from group II (*n* = 6 mice per group).

resulting supernatants were carefully decanted and the supernatants from the diazepam-treated animals were reconstituted with synaptosomal membranes from the vehicle-treated animals; membranes from vehicle-treated mice were reconstituted with the supernatants from diazepam-treated animals. The reconstituted membranes from both groups were incubated for 30 min at 0–4 °C before incubation with ^{3}H-diazepam.

Incubation (37 °C for 60 min) of crude synaptosomal membranes from mice treated with diazepam 12 h (Fig. 2*a*) and 24 h (Fig. 2*b*) earlier resulted in a marked decrease in the number of drug-occupied receptors. This decrease seems to be the result of a temperature-induced dissociation of benzodiazepine from the receptor, as exchanging supernatants from the diazepam-treated and vehicle-treated animals results in the detection of 'occupied receptor' in membranes from vehicle-treated mice. Furthermore, the decrease in the number of drug-occupied receptors in incubated diazepam-treated membranes is directly proportional to the increase observed in the control membranes following incubation with the 'diazepam-treated' supernatant (Fig. 2*a*, *b*). The presence of pharmacologically active benzodiazepine in the supernatant (S_2) from the incubated diazepam-treated membranes was confirmed using a radioreceptor assay[8].

These results demonstrate a close association between the number of drug-occupied benzodiazepine receptors and the anticonvulsant activity of diazepam. In contrast, the total concentration of 'free' benzodiazepine in brain is poorly correlated with its anticonvulsant effects. Only a small fraction (25–30%) of the total number of benzodiazepine receptors need be occupied to manifest a complete anticonvulsant effect. This observation could indicate the presence of 'spare receptors' similar to that reported for various peripheral hormonal and neurotransmitter systems[10]. Alternatively, a specific population of benzodiazepine receptors may be involved in the anticonvulsant effects of diazepam, and the correlation obtained reflects preferential binding of diazepam to these receptors[11]. In addition to providing evidence for the importance of the benzodiazepine receptor in mediating the anticonvulsant effects of the benzodiazepines, these findings represent the first direct correlation between the occupation of a central receptor site and the clinical effects of a drug. Furthermore, they suggest that the benzodiazepine receptor and its presumed endogeneous ligand(s)[12] may normally be involved in preventing the discharge or spread of seizure activity within the CNS.

The mice were obtained from the Veterinary Resources Branch, NIH. B.A.P. was a fellow of the COSTEP program, USPHS, during these studies.

Glycyrrhizic acid inhibits virus growth and inactivates virus particles

Raffaello Pompei, Ornella Flore, Maria Antonietta Marccialis, Alessandra Pani & Bernardo Loddo

Institute of Microbiology II, University of Cagliari, Italy

Screening investigations in antiviral action of plant extracts have revealed that a component of *Glycyrrhiza glabra* roots, found to be glycyrrhizic acid, is active against viruses. We report here that this drug inhibits growth and cytopathology of several unrelated DNA and RNA viruses, while not affecting cell activity and ability to replicate. In addition, glycyrrhizic acid inactivates herpes simplex virus particles irreversibly.

The effects of glycyrrhizic acid (ammonium salt, Fluka, Buchs) on growth of vaccinia, herpes simplex type 1, Newcastle disease, vesicular stomatitis (Indiana type) and polio type 1 viruses (all provided by NIH) in cultures of human aneuploid HEp2 cells (ATCC, Rockville) where studied. Twenty-four-hour-old cell monolayers (10^7 cells per sample) were infected with 5 infectious units per cell of each virus at 20 °C for 1 h, washed 3 times in Hank's balanced saline solution (BSS) and incubated at 37 °C for 18 h in Eagle's minimum essential medium (MEM) supplemented with 2% calf serum (*p*H 7.4). Infectious virus yield was determined by the Dulbecco and Vogt technique[1], slightly modified for vaccinia and herpes simplex type 1 viruses[2]. Cytopathic effects were evidenced by light microscope observation of Giemsa-stained cells and by measuring spectrophotometrically at 530 nm the amount of neutral red incorporated by cell cultures (100 μg ml^{-1}, 1-h pulses in a drug-free medium) after solubilisation in 1% sodium deoxycholate in BSS (*p*H 7.4)[3].

As shown in Table 1, addition of 8 mM glycyrrhizic acid to infected cell cultures soon after incubation at 37 °C completely inhibits both growth and cytopathic effects of vaccinia, herpes simplex type 1, Newcastle disease and vesicular stomatitis viruses. Protection of cell cultures from viral damage is so effective that, in spite of the total infection produced by the virus input used, differences can hardly be found at microscopic observation levels between drug-treated infected cells and uninfected controls. Later treatment (3 h post-infection) of cell cultures with 8 mM glycyrrhizic acid still suppresses virus replication and stops the progress of the cytopathic effect. Glycyrrhizic acid is also active on virus growth at 4 mM and at 2 mM, but not at 1 mM (data not shown). On the other hand, glycyrrhizic acid is without effect on poliovirus type 1.

Glycyrrhizic acid treatments that were inhibitory to virus growth were tolerated by cell cultures.

Uninfected cells incubated at 37 °C for 36 h in the presence of 8 mM glycyrrhizic acid remained unaltered both morphologically (evaluated as above) and in their ability to incorporate

Table 2 Effects of glycyrrhizic acid on uninfected cell cultures

Glycyrrhizic acid in medium	^{14}C amino acid uptake* (c.p.m.)	No. of cells per ml of medium†
—	76.705 (74.534–80.212)	7.1×10^5 ($6.2\times10^5-7.9\times10^5$)
8 mM	73.952 (71.528–77.334)	5.2×10^5 ($4.2\times10^5-6.4\times10^5$)

Figures are mean values of six determinations. The range of values is given in parentheses.

* ^{14}C amino acid uptake (0.3 μCi ml^{-1}, 1-h pulses) was measured after 35 h at 37°C in Eagle's MEM 2% serum.

† Initial inoculum, 2.5×10^5 cells ml^{-1}. Count made after 36 h at 37° C in Eagle's MEM 7% serum.

amino acids in acid-insoluble form[4], as determined by 1-h pulses of ^{14}C-protein hydrolysate (40 mCi mmol^{-1}, 0.3 μCi ml^{-1}, Amersham) (Table 2). Addition of 8 mM glycyrrhizic acid to 4-h-old cell cultures incubated in Eagle's MEM 7% calf serum had virtually no effect on cell growth. Thoma chamber counts of cells suspended by trypsin (0.25%, Difco) revealed a 28% decrease in cell growth in the respect of untreated controls, after 36 h at 37 °C.

Taking into account that in antiviral tests glycyrrhizic acid was allowed to act on infected cultures for 18 h (the time required for growth of all viruses in untreated controls), these data indicate that the antiviral effect of this drug is not mediated by damaging the cells.

Apart from inhibiting growth of several viruses, glycyrrhizic acid also produces irreversible inactivation of herpes simplex virus type 1. Suspensions of this virus suffer a loss of infectivity of 10^5 when incubated at 37 °C with 8 mM glycyrrhizic acid for only 15 min. Similar treatments do not inactivate the other viruses (at least irreversibly), even if prolonged for 3h.

Table 3 Inactivating effect of glycyrrhizic acid on virus particles

Virus strain	Incubation mixture at 37°C	i.u. Evidenced*
Vaccinia	in MEM	5.3×10^7
	in 8 mM GA	5.6×10^7
Herpes simplex type 1	in MEM	1.2×10^7
	in 8 mM GA	1.3×10^2
Newcastle disease	in MEM	3.9×10^7
	in 8 mM GA	4.2×10^7
Vesicular stomatitis	in MEM	4.3×10^7
	in 8 mM GA	3.1×10^7
Polio type 1	in MEM	6.1×10^7
	in 8 mM GA	3.9×10^7

* By the Dulbecco and Vogt method[1] in incubation mixtures diluted in drug-free MEM.

5×10^7 i.u. of each virus was incubated for 180 min, except in the case of herpes simplex type I in 8 mM GA, which was for 15 min. GA, glycyrrhizic acid.

Data from current research had led us to hypothesise that glycyrrhizic acid interacts with sensitive virus proteins both at the virionic stage and later on, when these proteins are synthesised in host cells. This is, however, a working hypothesis that has yet to be verified experimentally.

Ca^{2+}-induced fusion of phospholipid vesicles monitored by mixing of aqueous contents

Jan Wilschut & Demetrios Papahadjopoulos

Cancer Research Institute, University of California, School of Medicine, San Francisco, California 94143

Ca^{2+} has a central role in various cellular phenomena involving membrane fusion[1–3]. However, little is known about the mechanisms involved. Model membrane systems such as phospholipid vesicles have been used extensively to study the mechanism of membrane fusion at the molecular level[4]. For example, phosphatidylserine (PS) vesicles have been shown to undergo massive aggregation and structural rearrangements on addition of Ca^{2+}, with eventual formation of large cochleate structures[5–8]. Although these structures do not retain appreciable internal volume, their formation has been proposed to result from fusion of the initial vesicles[5–8]. The significance of the PS–Ca^{2+} system as a model for biological membrane fusion has been questioned recently by Ginsberg[9]. Based on the observation that divalent cations induce the release of contents from PS vesicles but fail to bring about the uptake of a marker from the medium, he proposes that the vesicles are ruptured completely during interaction with divalent cations and reassemble subsequently to form large non-vesicular structures. The present study demonstrates that the question raised by Ginsberg[9] is not particularly relevant to the phenomenon concerned, and that his experimental observations do not allow the exclusive conclusion that Ca^{2+} induces lysis of PS vesicles rather than fusion.

With respect to the question of 'lysis or fusion', in general, membrane fusion is not necessarily a completely non-leaky process. Therefore, release of vesicle contents induced by

0028–0836/79/430690—03$01.00

divalent cations does not preclude a fusion event being involved. However, the question of whether the release of contents depends on mutual interaction between the vesicles is crucial. Our recent observation that Ca^{2+}-induced leakage of PS vesicle contents is approximately second-order with respect to vesicle concentration[8] indicates that vesicle–vesicle interaction is a prerequisite for the observed release and suggests that leakage from separate PS vesicles does not occur. The observation by Ginsberg that Ca^{2+} fails to bring about the uptake or entrapment of markers from the external medium into the vesicles[9] can be completely reconciled with earlier results[5,6] regarding the formation of large cochleate structures from PS vesicles by interaction with Ca^{2+}. These cochleates have been shown to result from the eventual collapse of the vesicles and, therefore, do not retain any encapsulated volume[7,8]. This is indicated by the very short lamellar distance of 53 Å in the PS–Ca^{2+} membrane system, determined by X-ray diffraction[7], and the absence of any appreciable amounts of water between the bilayers in the final complex[8]. Consequently, it is highly unlikely that solutes from the medium would be taken up and retained in the structure during a 1-h incubation. However, the final formation of such a tightly packed PS–Ca^{2+} membrane complex does not necessarily lead to the conclusion that the sequence of events involved is one of lysis of separate vesicles with subsequent reassembly into non-vesicular structures, as proposed by Ginsberg[9]. As the author admits, fusion might occur during the initial stages of the interaction between vesicles. However, the design of his experiments did not permit investigation of the early events in this process.

To be able to follow the kinetics of vesicle fusion phenomena, we have developed an assay which meets the rigorous criterion of mixing of vesicle contents. The method is based on the interaction between terbium (Tb^{3+}) ions and dipicolinic acid (DPA)[10–12]. Formation of the $Tb(DPA)_3^{3-}$ complex produces a 10^4-fold enhancement of the Tb fluorescence[11,12]. The design of the assay involves encapsulation of $TbCl_3$ in one population of vesicles and DPA in another. $TbCl_3$ is encapsulated in the presence of a 10-fold molar excess of citrate as a weak chelator, which prevents interaction of Tb^{3+} with the negatively charged lipid. DPA is encapsulated at a 10-fold higher molar concentration than $TbCl_3$. On fusion of the two types of vesicle the Tb^{3+}–citrate complex is expected to dissociate in favour of the formation of the chelation complex between Tb^{3+} and dipicolinate, due to the very high affinity of the latter for Tb^{3+} (ref. 10). Release of vesicle contents is not registered as fusion because Ca^{2+} and EDTA, both present in the external medium, strongly interfere with the formation of the fluorescent $Tb(DPA)_3^{3-}$ complex through their interaction with DPA and Tb^{3+}, respectively. Introduction of 0.1 mM EDTA into a solution containing 1 μM $TbCl_3$, 10 μM citrate and 10 μM DPA in the buffer in which the fusion assay is done produces a 90% decrease of the fluorescence intensity. The additional presence of Ca^{2+} at a concentration of 1 mM or higher further reduces the fluorescence intensity to 1% of the maximal value. Moreover, during the fusion assay the quenching potencies of Ca^{2+} and EDTA will be even more pronounced, as the overall Tb, citrate and DPA concentrations are about seven-fold lower than those in the control experiment mentioned above. Consequently, only mixing of vesicle contents, separated from the outside medium, is registered as fusion. An additional advantage of this assay is that the formation of the $Tb(DPA)_3^{3-}$ complex is extremely fast and thus allows an accurate kinetic analysis of the initial events during vesicle-vesicle interactions. A more extensive account of the assay will be presented elsewhere.

Figure 1 shows the kinetics of mixing of vesicle contents induced by 1.5 mM Ca^{2+} in a 1:1 mixture of two PS vesicle populations containing Tb and DPA, incorporated in separate vesicles, as monitored by the increase of Tb fluorescence (solid line). The design of the fluorimeter permitted the simultaneous recording of the kinetics of vesicle aggregation, as measured by light scattering (dotted line). In addition, Fig. 1 shows the release of carboxyfluorescein (CF) from a similar vesicle preparation induced by the same Ca^{2+} concentration (dashed line). It is apparent from these results that Ca^{2+} induces a very rapid mixing of the vesicle contents, which occurs on the same time scale as the initial aggregation. To exclude the possibility that the observed increase in fluorescence resulted from the formation of $Tb(DPA)_3^{3-}$ complexes in close proximity but outside the vesicles, possibly due to release to locally high concentrations,

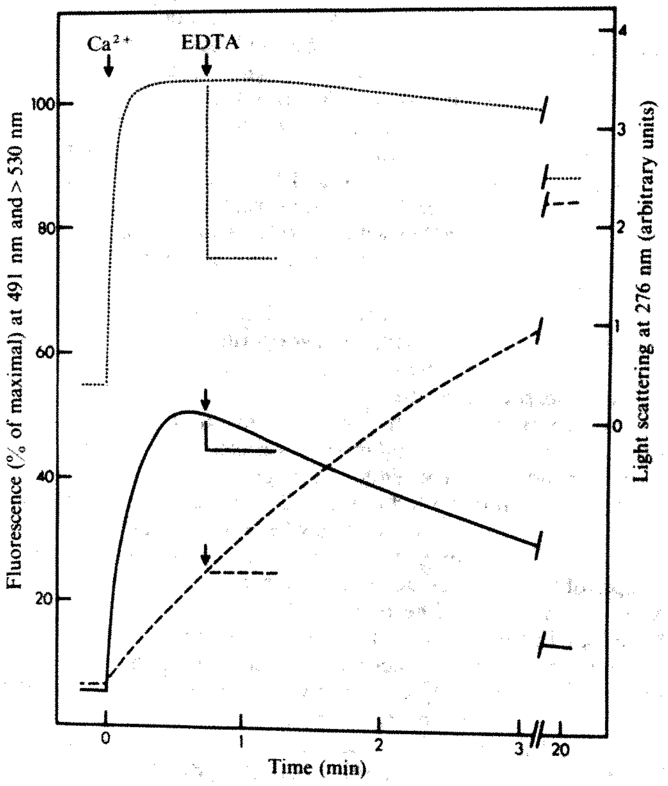

Fig. 1 Calcium-induced fusion of PS vesicles and release of vesicle contents. Unilamellar vesicles were prepared from bovine brain phosphatidylserine (PS) by sonication under nitrogen in a bath-type sonicator for 1 h at 20 °C (ref. 6). Lipid concentration during sonication was 10 μmol ml^{-1}. Thin-layer chromatographic analysis[17] of the lipid in vesicle preparations after sonication (with a load of 6 μg of lipid phosphorus per spot on the thin-layer plate) showed no detectable amounts of degradation products such as lyso-PS and fatty acids. Vesicles were prepared in (1) 10 mM $TbCl_3$/100 mM sodium citrate/2.0 mM L-histidine/2.0 mM N-Tris(hydroxymethyl)methyl-2-aminoethanesulphonic acid (TES), *p*H 7.4; (2) 100 mM sodium dipicolinate (DPA)/2.0 mM L-histidine/2.0 mM TES, *p*H 7.4 or (3) 100 mM carboxyfluorescein (CF)/2.0 mM L-histidine/2.0 mM TES, *p*H 7.4, and separated from non-encapsulated material by gel filtration on Sephadex G-75. Elution buffer, 100 mM NaCl/2.0 mM L-histidine/2.0 mM TES/1.0 mM EDTA, *p*H 7.4. Phospholipid phosphorus was determined as described in ref. 18. Carboxyfluorescein was purified as described in ref. 13. All chemicals were of the highest purity available[8]. Fusion experiments were carried out in quartz fluorescence cells containing 1.0 ml of 100 mM NaCl/2.0 mM L-histidine/2.0 mM TES/0.1 mM EDTA, *p*H 7.4, at a total lipid concentration of 100 μM. Tb- and DPA-containing vesicles were mixed in a 1:1 ratio, 50 μM each. The solution was stirred with a magnetic stirring bar and the temperature was maintained at 25 °C. $CaCl_2$ was injected as a 100 mM solution to a final concentration of 1.5 mM. In separate experiments EDTA was injected as a 100 mM solution, 45 s after the addition of $CaCl_2$, to a final concentration of 5.0 mM. Fluorescence was measured in an SLM-4000 instrument (SLM Instruments) with a 'T'-design, permitting simultaneous recording of 90° fluorescence and 90° light scattering. Excitation of Tb fluorescence was at 276 nm, emission was detected at 491 nm (solid line), and light scattering was measured using a Corning 7-54 bandpass filter (dotted line). Excitation of CF fluorescence was at 460 nm and emission was measured at >530 nm using a Corning 3-68 cut-off filter (dashed line). The value of 100% Tb fluorescence was determined in the presence of 20 μM DPA by releasing the contents from 50 μM Tb-containing vesicles (freed from EDTA on Sephadex G-75) with 0.5% (w/v) sodium cholate. Maximal CF fluorescence was determined in the presence of 0.1% (v/v) Triton X-100. Fluorescence intensity is presented as a percentage of the maximal values. The light scattering is expressed in arbitrary units; note that the curve is shifted on the vertical scale.

we added excess EDTA to the mixture to terminate the fusion reaction once the maximum level of fluorescence had been attained. As shown in Fig. 1, the fluorescence intensity could be maintained at a high level, indicating a physical separation of the fluorescent complex from the external EDTA-containing medium. Although release of vesicle contents, as monitored by increasing CF fluorescence[8,13], started immediately after Ca^{2+} addition, its rate was considerably lower than that of the Tb fluorescence increase. This indicates that fusion proceeds more rapidly than the release of vesicle contents. The Tb fluorescence reached its maximal level, corresponding to ~50% of the total amount of Tb present, within 45 s after the addition of Ca^{2+}. At that time, only 20–25% of the CF had been released. On addition of 2.0 mM Ca^{2+}, rather than 1.5 mM, the maximal level of Tb fluorescence approached 65% (not shown). These observations imply that multiple fusion events must occur, for otherwise, assuming no release at all, in a 1 : 1 mixture of the two types of vesicle only a maximum of 50% of the Tb can become associated with DPA. The eventual decrease of the Tb fluorescence (Fig. 1) is consistent with the release and dissociation of the $Tb(DPA)_3^{3-}$ complex in the medium. Addition of EDTA, 45 s after the addition of Ca^{2+} (Fig. 1) not only produces a constant high level of Tb fluorescence, but also stops CF release and induces a decrease in the light scattering to a level which is considerably higher than the level before Ca^{2+} addition, indicating increased vesicle size.

From the present results, we conclude that Ca^{2+} induces extensive fusion of PS unilamellar vesicles as monitored by mixing of aqueous contents. Leakage of vesicle contents, although remaining limited initially, does occur. Consequently, Ca^{2+} can slowly enter the vesicles where it can bind to the PS molecules of the interior monolayer, causing subsequent collapse of the fused vesicles and further release of contents. The assay system described here has made it possible to distinguish the initial fusion of PS vesicles from the release of vesicle contents. Studies with vesicles composed of various lipid mixtures are now in progress to investigate the possibility of producing vesicles which are capable of fusing but are more resistant to leakage than vesicles composed of pure PS. In any case, the present results and other recent reports[8,14–16] indicate that Ca^{2+}-induced vesicle fusion is quite relevant to biological membrane fusion phenomena, and could considerably enhance our understanding of the mechanism of such events at the molecular level.

$TbCl_3 \cdot 6H_2O$ was obtained from Alfa, dipicolinic acid from Sigma and carboxyfluorescein from Eastman Kodak. One of us (J.W.) is on leave from the University of Groningen, supported by the Netherlands Organisation for the Advancement of Pure Research (ZWO). This work was supported by grant GM 26369 from the NIH.

Differences in A and B forms of monoamine oxidase revealed by limited proteolysis and peptide mapping

Richard M. Cawthon & Xandra O. Breakefield*

Department of Human Genetics, Yale University School of Medicine,
New Haven, Connecticut 06510

Monoamine oxidase (MAO, EC 1.4.3.4) is a mitochondrial outer membrane enzyme which deaminates amine transmitters in the nervous system and biogenic amines throughout the body. At least two types of MAO activity have been identified which differ in their specificities for substrates and sensitivities to inhibitors[1–3]. Type A preferentially deaminates 5-hydroxytryptamine and noradrenaline and is more sensitive to inhibition by clorgyline. Type B deaminates phenylethylamine and benzylamine and is more sensitive to inhibition by deprenyl. Tissues from several species express MAO A alone, MAO B alone, or both types of MAO. Furthermore, the two types of activity follow different developmental sequences in certain tissues. Models to explain the molecular and genetic regulation of this enzyme[4] raise two questions: (1) are there different enzyme molecules associated with A and B types of activity, and (2) if there is only one enzyme molecule, how do differences in the microenvironment of this enzyme within the outer mitochondrial membrane produce two types of activity? Attempts to separate and purify the different types of activity have involved solubilisation and lipid extraction procedures that alter the kinetics of the enzyme and differentially affect the A and B types of activity[5–8]. Immunological studies[9,10] have produced equivocal results. None of these observations has elucidated the molecular basis of the differences between the types of MAO activity. Here, we have used the technique of proteolytic digestion and peptide mapping to demonstrate that there are distinct enzyme molecules associated with the A and B types of MAO activity. This finding implies that the A and B forms of MAO may be coded for by separate gene loci and represent evolutionarily related proteins which have diverged in function.

Pargyline, an irreversible inhibitor of both A and B types of MAO activity[11–16], binds stoichiometrically to MAO, forming a stable adduct with the flavin residue[16]. This reaction is specific for MAO and does not occur with other purified flavoproteins[17]. Pargyline binding was used with limited proteolysis and one-dimensional peptide mapping, an effective technique for detecting differences and similarities in the amino acid sequences of proteins of similar molecular weights (MWs)[18–20]. The pattern of fragments obtained is highly reproducible and characteristic for a given substrate protein and proteolytic enzyme. As they are known to have similar MWs[14,15], the structure of the A and B forms of MAO in rat hepatoma cells was investigated by site-specific proteolysis in the presence of SDS, followed by electrophoresis in SDS-polyacrylamide gels to identify peptide fragments.

Following binding of ^3H-pargyline to crude mitochondrial preparations, proteins were fully solubilised and denatured by heating in high concentrations of SDS in reducing conditions (see Fig. 1 legend), and electrophoretically separated on SDS-polyacrylamide gels. Figure 1 shows ^3H-pargyline-labelled peptide fragments detected when radiolabelled MAO was isolated and exposed to *Staphylococcus aureus* V8 protease and further SDS-polyacrylamide gel electrophoresis. The peptide maps in each panel are chosen to illustrate all the fragments obtained when identical samples of ^3H-pargyline-labelled MAO were incubated with five concentrations of protease. The first three panels display proteolytic fragments of MAO from rat

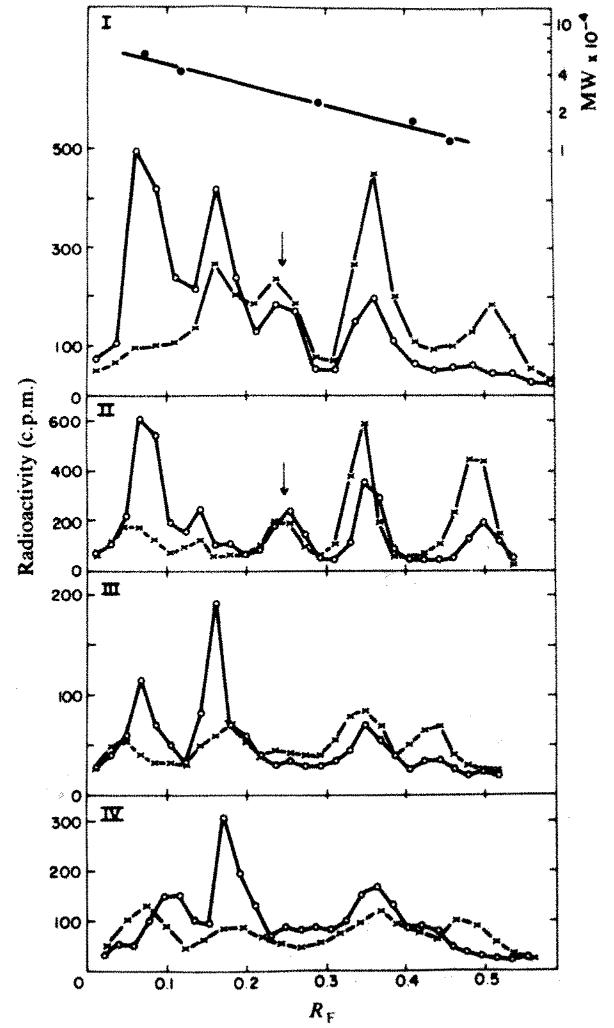

Fig. 1 Peptide maps of the A and B forms of MAO produced by limited proteolysis with *S. aureus* V8 protease and electrophoresis in 15% SDS-polyacrylamide gels. The migration relative to the tracer dye front (R_F) is plotted on the abscissa, and the radioactivity of each slice and the MW are plotted on the left and right ordinates, respectively. The conditions and procedures used to grow and subculture the cell lines used were as described previously[14], except that for subculturing, cells were resuspended in isotonic buffered saline containing no Ca^{2+} or Mg^{2+} and supplemented with 1 mM EDTA. Crude mitochondrial fractions were prepared from cultures collected at confluency as described elsewhere[14], and stored at −20 °C or used immediately. To label MAO, mitochondrial preparations (400 μg protein per sample) were incubated with 0.29 nmol [^{3}H-benzylmethylene]pargyline (6.86 Ci mmol^{-1}, NEN) in a final volume of 1.0 ml 50 mM Tris-HCl, *p*H 7.5, for 60 min at 37 °C in a shaking water bath. Preparations in panel II were preincubated with 0.1 μM clorgyline at 37 °C for 30 min before addition of ^{3}H-pargyline. Preparations in panel III were preincubated with 1.0 μM deprenyl at 37 °C for 15 min before addition of ^{3}H-pargyline. To ensure that the drugs did not interfere with the proteolysis of MAO, some mitochondrial preparations were incubated with clorgyline or deprenyl only after the ^{3}H-pargyline radiolabelling step. When all incubations were completed, the samples were centrifuged at 40,000*g* for 30 min at 4 °C. The radiolabelled mitochondrial pellets were resuspended in 160 μl of a loading solution containing 3% SDS, 0.15 M sucrose, 1% β-mercaptoethanol, 0.005% bromphenol blue, 3 mM EDTA and 0.0625 M Tris-HCl, *p*H 6.8, and proteins were solubilised by boiling for 5 min. Preparative polyacrylamide slab gel electrophoresis was carried out in a 7.5% acrylamide running gel (15 × 10 × 0.3 cm) with a 3% stacking gel (15 × 2 × 0.3 cm) both containing 0.1% SDS, using a modification[23] of the procedure of Maizel[24]. To locate the position of MAO in the preparative gel, a lane containing radiolabelled MAO and a lane containing standard MW marker proteins were sliced from the gel and stained and destained as described elsewhere[18]. The lane containing the mitochondrial sample was cut into 2-mm slices along a 2-cm section in the region of the 58,000 MW marker, catalase. The remainder of the preparative gel was stored, unstained, at −20 °C. The distribution of the radioactivity in the slices was determined quantitatively using a modification of the method of Horvitz[25] as recommended by NEN. Each slice was placed in a glass scintillation vial and 10 ml of a solution containing 5% Protosol and 7.5% Liquifluor (v/v, NEN) in toluene were added. Samples were incubated for 16 h at 37 °C and radioactivity was determined by liquid scintillation spectrometry. A single peak of radioactivity was observed in the sliced region, indicating the precise location of MAO. The remainder of the preparative gel was then thawed, stained and destained in <1 h[18], and cut to obtain nine gel slices, one 9 × 3 × 3-mm slice per lane, which contained the radiolabelled MAO. The slices, and the sample wells of the proteolytic gels, were treated using a modification[19] of the method of Cleveland *et al.*[18]. The proteolytic gels were prepared as described[18] except that they were cast 3 mm thick with sample wells 2.5 cm deep and 1.0 cm wide. Three gel slices containing radiolabelled MAO were stacked at the bottom of each sample well. Six identical samples of three slices each were routinely loaded onto each gel. A concentrated solution of *S. aureus* V8 protease (36-900-1, Miles), stored at −20 °C, was thawed, and serial dilutions were prepared and added to the sample wells in amounts of 0, 0.005, 0.025, 0.1, 0.5, and 2.5 μg per well. Standard MW marker proteins solubilised in loading solution (see above) were applied to the remaining sample well. The marker proteins used were catalase, 58,000 (Calbiochem); ovalbumin, 43,000; trypsin, 23,300; myoglobin, 17,200; cytochrome *c*, 12,400 (Sigma). Electrophoresis was carried out at a constant current of 45 mA, except for a 30-min period when current was turned off, after the tracer dye had neared the bottom of the stacking gel. Electrophoresis was continued until the bromphenol blue tracer dye in the marker lanes had moved ~10 cm into the running gel. The gels were then stained and destained in <1 h, as above. Each lane was cut into approximately 50 2-mm slices and the distribution of radioactivity in the slices was quantitated as described above. A plot of the mobilities of the marker proteins against the log of their MWs was used to estimate the MWs of the radiolabelled peptide fragments. Panels I, II and III show peptides from line MH_1C_1: I, mitochondria were labelled with ^{3}H-pargyline; II, mitochondria were incubated with clorgyline before ^{3}H-pargyline labelling; III, mitochondria were incubated with deprenyl before ^{3}H-pargyline labelling. Panel IV shows mitochondria from line C6, labelled with ^{3}H-pargyline. Each panel shows peptide patterns from two of the five concentrations of protease tested. These patterns were chosen because they included all the peptide fragments observed at all protease concentrations. Results shown are from one of two or three similar experiments. Control samples of MH_1C_1 incubated with clorgyline or deprenyl only after ^{3}H-pargyline labelling yielded peptide maps essentially identical to that in panel I. In control samples not treated with protease, all radioactivity above background levels was found in the leftmost peak, corresponding to the MW of intact MAO—57,000.

hepatoma line, MH_1C_1. Panel I shows peptide fragments derived when both the A and B forms of MAO were labelled. Panel II shows peptides exclusively from the B form, as binding of ^{3}H-pargyline to the active site of type A MAO was blocked by preincubation of the mitochondrial preparations with clorgyline. Panel III shows labelled peptides exclusively from the A form, as binding of ^{3}H-pargyline to the active site of type B MAO was blocked by preincubation with deprenyl. The ^{3}H-pargyline-labelled peptides displayed in panel IV resulted from limited proteolysis of MAO from rat glioma line C6. This cell line has only type A MAO activity[21] and was derived from a different strain of rats from the MH_1C_1 line.

A peptide fragment of approximately MW 29,000 is prominent in the maps shown in panels I and II, but is missing from the maps in panels III and IV. This fragment was present only when the B form of MAO was labelled. The other three fragments in the maps were common to both A and B forms of MAO. In preliminary studies the proteolytic enzyme papain was found to generate four ^{3}H-pargyline-labelled peptide bands (MW >10,000) which were common to both forms of MAO. Proteolysis by chymotrypsin produced two labelled bands common to A and B and one band unique to the A form (data not shown).

The flavin-containing polypeptides which underlie the A and B types of MAO activity in the rat are similar in MW[14,15]. Furthermore, radiolabelled MAO A and B from rat hepatoma and glioma cells have identical mobilities (M.R.C. Costa and X.O.B., unpublished) in a non-equilibrium *p*H gradient gel system[22], showing they also have a similar charge. Discrete regions in these polypeptides were analysed using site-specific proteases in denaturing and solubilising conditions for MAO. The different peptide maps obtained for MAO A and B indicate differences in the location of the target sites for the protease, or in their susceptibility to proteolysis. These differences could result from divergent amino acid sequences or differential post-translational modifications. Such molecular differences may determine the association of these polypeptides with other molecules, and the final position and conformation of the enzyme within the mitochondrial membrane. An important hypothesis that is ruled out by these data is that the differences underlying the A and B types of MAO activity are solely due to the membrane microenvironments of identical enzyme molecules.

We thank Dr Maria R. Castro Costa for discussions and Seth Alper for advice in setting up the proteolytic gel system. The rat cell lines were obtained from the American Type Culture Collection. Clorgyline was provided by Dr Sabit Gabay, and deprenyl by Professor J. Knoll. This work was supported by PHS grants GM20124 and NS12105.

Note added in proof: Using SDS-polyacrylamide gel electrophoresis (SDS-PAGE), Callingham and Parkinson found that in rat tissues the pargyline binding polypeptides associated with type A and B MAO activities have MWs of 60,000 and 55,000, respectively (MAO Symposium, Midland, Michigan, 1979). We subsequently modified our SDS-PAGE technique and have now demonstrated a similar MW difference for these polypeptides in rat hepatoma cells, providing additional support for the conclusion that MAO A and B are distinct enzyme molecules.

Structure of two spliced mRNAs from the transforming region of human subgroup C adenoviruses

Michel Perricaudet

Recombination et expression génétique (Institut National de la Santé et de la Recherche Médicale U163), Unité de Génie Génétique, Institut Pasteur, 28 rue du Dr. Roux, 750 15 Paris, France

Department of Microbiology, University of Uppsala, Box 581,
S-751 23 Uppsala, Sweden

The papova viruses and the human adenoviruses are widely used as a model system to study cell transformation *in vitro*. In subgroup C human adenoviruses, fragment *Hpa*I-E, which comprises as little as 4.5% of the adenovirus type 5 (ad5) DNA, is sufficient for transformation of rat embryo cells[1]. Analysis of messenger RNAs (mRNAs) from the transforming region of adenoviruses type 2 (ad2) has identified several spliced mRNA species[2–4]. Promoter mapping studies indicate that the leftmost early region contains two separate transcription units, E1A and E1B (ref. 5) (Fig. 1*a*). Region E1A is approximately equivalent *Hpa*I-E. The complete nucleotide sequence of the *Hpa*I-E fragment of ad5 was recently reported[6]. However, the spliced nature of early adenovirus mRNAs prevents a prediction of the amino acid sequence of the corresponding polypeptides directly from the DNA sequence. To study the structure of early ad2 mRNAs at the nucleotide level, we have used molecular cloning procedures to amplify the appropriate mRNA sequences. In this report, clones corresponding to the 12S and 13S mRNA from region E1A (Fig. 1*c*) have been isolated and characterised by hybridisation and sequence analysis. Our results enable us to predict the primary sequence of two related polypeptides from region E1A of human subgroup C adenoviruses.

To clone early ad2 mRNAs, double-stranded complementary DNA (cDNA) copies were inserted into the *Pst*I site of plasmid pBR322 after dG/dC tailing with terminal transferase. Clones containing ad2-specific sequences were identified by hybridisation[7], using ad2 DNA or specific fragments of ad2 DNA as probes. In this way three clones were identified which contain sequences from region E1A of the ad2 genome. These clones are designated 147, 131 and 133. Plasmid DNA was extracted from these clones, labelled *in vitro* by nick translation and hybridised to *Sma*I fragments of ad2 DNA. Plasmid DNA from clones 131 and 133 hybridised to both fragments *Sma*I-J and *Sma*I-E (map coordinates 0–2.9 and 2.9–10.7) whereas clone 147 hybridised exclusively to fragment *Sma*I-E (Fig. 2).

The clones were further analysed by restriction enzyme cleavage using endonucleases *Hpa*I, *Xba*I, *Sma*I and *Pst*I. Because the cDNAs were inserted into the *Pst*I site of plasmid pBR322 by dG/dC tailing, endonuclease *Pst*I will excise the cDNA insert. Clone 147 contained a 440-nucleotide-long insert which lacked the cleavage site for *Sma*I whereas *Hpa*I cleavage resulted in two fragments, 130 and 310 base pairs long. From these results we conclude that clone 147 contains sequences corresponding to the 3′-end of a mRNA from region E1A (see Fig. 1*a–c*).

Clone 133 contained a cDNA insert 840 base pairs long that lacked a cleavage site for *Sma*I, whereas *Xba*I cleavage gave two fragments 620 and 220 base pairs long. These results together with the hybridisation results indicate that clone 133 corresponds to the 12S mRNA of region E1A (Fig. 1*c*).

The cDNA insert in clone 131 was approximately 650 base pairs long, and was cleaved precisely in the middle by *Sma*I. Cleavage with *Xba*I resulted in two fragments, 510 and 140 base pairs long. The presence of a cleavage site for *Sma*I in the cDNA insert suggests that clone 131 is related to the 13S mRNA of region E1A although it is not a complete copy of this mRNA.

To study the structure of the cloned mRNAs at the nucleotide level, sequence analysis according to the Maxam and Gilbert[8] procedure was carried out. The strategy for our sequencing approach is shown in Fig. 1*b* and *d*, which also outlines the results. The proposed sequence for the 12S and 13S mRNAs from region E1A is shown in Fig. 3. Although none of the clones contains a complete copy of the 12S or 13S mRNA, it was possible to combine our sequence results from the clones with the DNA sequence for the left-hand end of ad5 DNA[6] to deduce the structure of the two mRNAs. Both ad2 and ad5 belong to subgroup C adenoviruses and their transforming regions are nearly identical[9]. From our clones we have collected sequence information comprising more than 500 nucleotides (Fig. 1*d*) and have found only six base-pair changes between ad2 and ad5 DNA (Fig. 3). The sequence at positions where splicing takes place are in all cases identical between ad2 and ad5. Thus, it is possible to combine our sequence information from the clones with the genomic DNA sequence of ad5 (ref. 6) to deduce the structure of the 12S and 13S mRNAs from region E1A. The structure is based on the assumption that the 12S and 13S RNAs have common 5′- and 3′-ends.

The splicing events which must occur during maturation of the 12S and 13S mRNAs result in the deletion of a markedly AT-rich region, between nucleotides 1,113 and 1,228, which contains many stop codons. In this respect the splice has the same function as the splice in the mRNA for the large T-antigen

0028–0836/79/430694—03$01.00

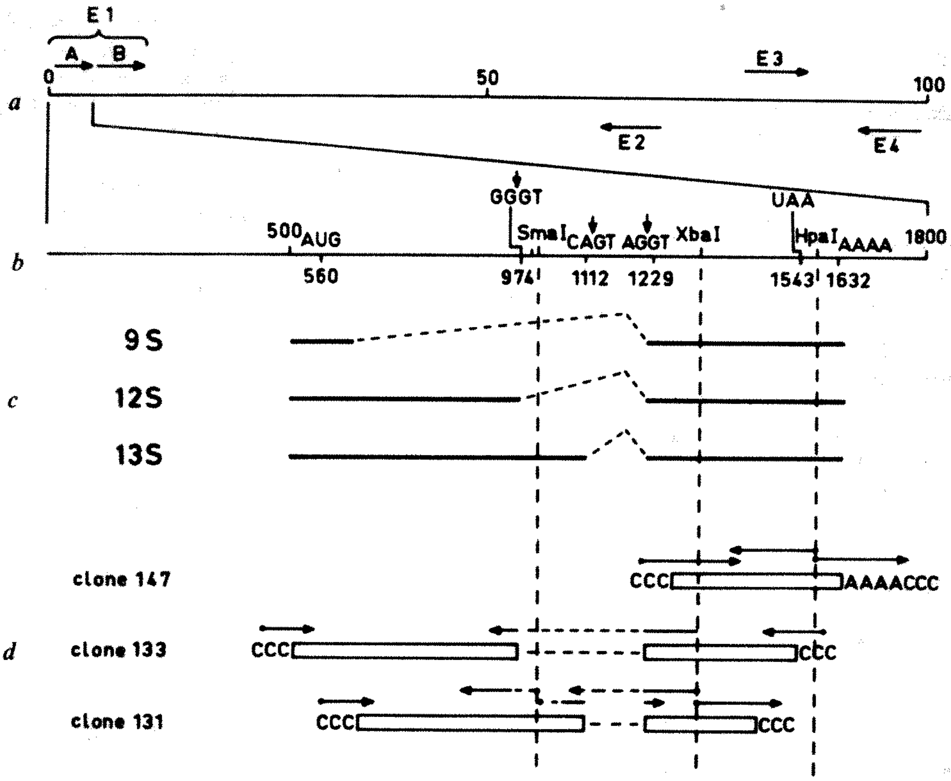

Fig. 1 A schematic drawing of the ad2 genome, showing the four regions which are transcribed early after infection.[18,19] Region E1 contains two promoters which divide it into E1A and E1B (ref. 5). An enlargement of region E1A, indicating cleavage sites for selected restriction enzymes. The locations of the initiator AUG, the termination codon, the poly(A) addition site and the splice points for the 12S and 13S mRNAs are indicated. The nucleotide sequences around the splice points are also shown. Due to the presence of tandem repeats at the splice points (GT in the 13S mRNA and GGT in the 12S mRNA) it is not possible to pinpoint precisely the positions where splicing has taken place. However, by following the 'GT–AG' rule (ref. 20) tentative locations for the splice points can be established and are indicated by arrows. Following this assumption, nucleotide 974 is connected to nucleotide 1,229 in the 12S mRNA, and in the 13S mRNA nucleotide 1,112 is connected to nucleotide 1,229. *c*, structure of the 9S, 12S and 13S mRNAs as determined by electron microscopy[4] and S_1 nuclease mapping[2]. *d*, The boxes indicate sequences which are present in clones 147, 133 and 131. The clones were prepared in the following way. Complementary DNA (cDNA) from 10 µg of poly(A)-containing RNA, prepared as described previously[21] was synthesised with avian myeloblastosis virus (AMV) DNA polymerase, using oligo(dT)$_{12-18}$ as a primer in 0.2 ml of a reaction mixture containing 50 nM Tris-HCl, *p*H 8.2, 10 mM KCl, 75 mM dithiothreitol, 10 mM $MgCl_2$, 4 mM sodium pyrophosphate, 0.05 mM $[\alpha\text{-}^{32}P]$ATP and 0.02 mM dGTP, dCTP and dTTP. The RNA template was removed by hydrolysis in 0.3 M NaOH for 2 h at 50 °C. A second DNA strand was synthesised either with DNA polymerase I or AMV DNA polymerase in the same reaction mixture as described above, without pyrophosphate. The resulting hairpin loop was eliminated by S_1 treatment. The double-stranded cDNA was inserted into the *Pst*I site of the pBR322 plasmid after dG/dC tailing with terminal transferase. The recombinant plasmids were propagated in the DP50 strain of *Escherichia coli* in EK 2 host–vector conditions. The experiments were carried out in the P3 facilities available at the Pasteur Institute, Paris. Details of our cloning procedure will be described elsewhere[15]. Colonies containing ad2-specific sequences were identified by hybridisation[7]. The arrows indicate regions which were sequenced by the Maxam and Gilbert[8] procedure.

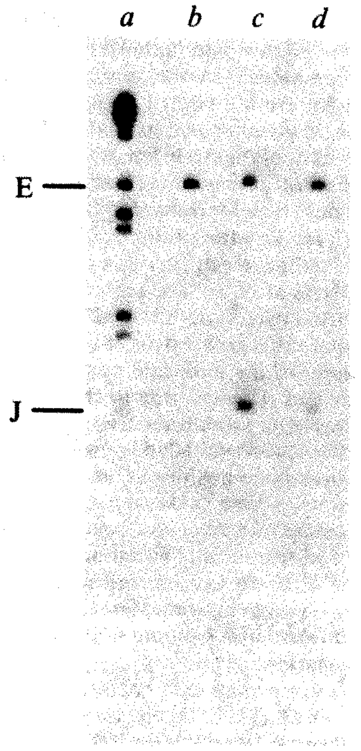

Fig. 2 Hybridisation between ^{32}P-labelled DNA from clones 147 (*b*), 133 (*c*), 131 (*d*) and *Sma*I fragments of ad2 DNA. DNA from the recombinant plasmids was labelled *in vitro* by nick translation. Ad2 DNA was cleaved with *Sma*I and transferred to nitrocellulose[22]. Hybridisation was visualised by autoradiography. ^{32}P-labelled and ad2 DNA was hybridised to indicate the position of all fragments (*a*).

of SV40 (refs 10–12). Also, like the situation for SV40 T-antigen mRNA[13], the 5'- and 3'-parts of both mRNAs will be translated from different reading frames. In this way the coding capacity of region E1A is used in the most efficient way. The polypeptides which are specified by the 13S and 12S mRNAs will be 288 and 242 amino acids long (Fig. 3), with molecular weights of 32,000 and 26,000, respectively, assuming that the AUG at position 560 is used for initiation. Both polypeptides will have identical amino- and carboxy-terminal ends, their only difference being a deletion of 46 internal amino acids from the polypeptide, specified by the shorter mRNA (Fig. 3). Both peptides are unusually rich in proline and glutamic acid (Fig. 3); this may explain why their molecular weights have been overestimated by SDS-polyacrylamide gel electrophoresis[14]. By *in vitro* translation of mRNAs from the extreme left-hand end of the ad2 genome, four polypeptides in the molecular weight range of 42–53,000 have been detected[14]. Thus, more polypeptides have been assigned to region E1A than can be accounted for by the mRNAs which have been observed by electron microscopy[4] and the S_1 nuclease assay[2]. This could be due to post-translational modification or processing of the primary translation products. However, we cannot exclude the possibility that additional mRNAs are specified by region E1A which have such small differences in the positions of their splices that they have escaped detection. Sequence analysis of additional clones is clearly required to resolve this problem. The 3'-end of region 1A mRNAs has been positioned to nucleotide 1,632. However, as two As follow the T in the DNA sequence, it is not possible to predict precisely where the poly(A) addition occurred. We have made a similar observation for the poly(A) addition site in the mRNA for adenovirus polypeptide IX[15] and the presence of two or more As at the poly(A) addition site may be a common feature. Our results do not exclude the presence of

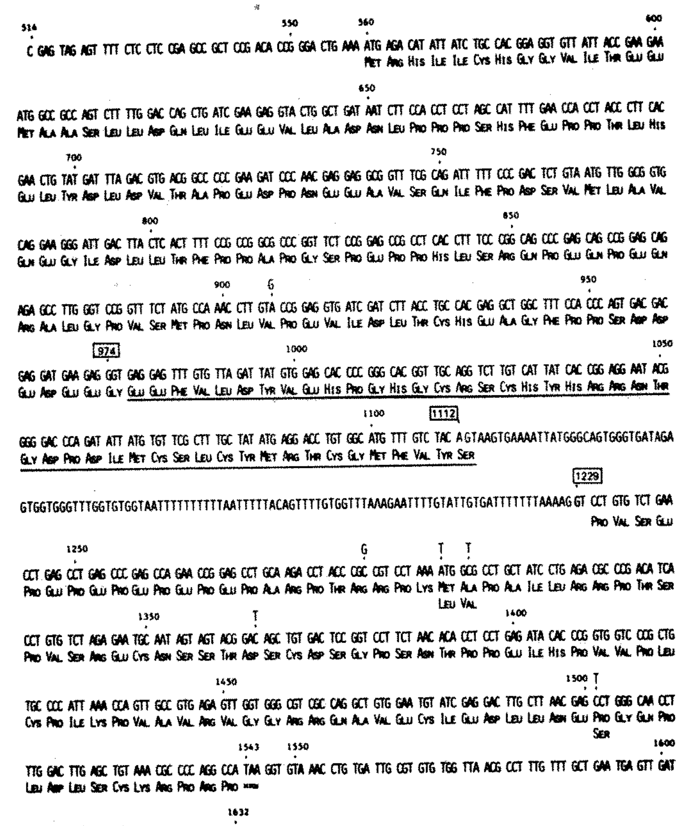

Fig. 3 The proposed structure for the 13S mRNA as deduced from our analysis of the mRNA clones together with the sequence for the left hand end of ad5 DNA[6] (J. Maat *et al.*, personal communication). The sequence corresponds to the 13S mRNA from ad5. Differences between the ad2 and ad5 sequences as noted in our present study are indicated. The 5'-end of region E1A mRNAs is not defined by our cloned sequences. Nucleotide 514 is the first nucleotide present in clone 133. The true 5'-end is probably located a few nucleotides upstream from this position. The sequence which is absent in the 12S mRNA is underlined. The hexanucleotide, present close to the poly(A) junction of eukaryotic mRNAs[16], is indicated by the box. Nucleotides which become connected after splicing are shown in boxes (see also Fig. 1*b*). The nucleotide sequence is indexed according to the method of van Ormondt *et al.*[6].

other poly(A) addition sites for region 1A mRNAs, as only one poly(A) junction has been sequenced so far. This seems, however, unlikely, because a single hexanucleotide sequence, AAUAAA, is present in the DNA sequence[6] and this sequence has been found to precede the poly(A) junctions of all eukaryotic mRNAs[16]. Sequence analysis of clone 133 places the 5'-end of region 1A mRNAs at nucleotide 514 in the sequence of van Ormondt *et al.*[6]. It is, however, conceivable that a few nucleotides are missing from this clone, as the second strand of the cDNA was synthesised by looping back the first strand. Furthermore, a promoter-like sequence, TATTTATA, starts 39 nucleotides upstream from position 514. Such sequences are usually found 23–26 nucleotides preceding the cap-site (D. Hogness, personal communication and ref. 17).

Independent of this investigation, Baker and Ziff (manuscript in preparation) have identified and analysed the capped T_1 oligonucleotide from region E1A mRNAs. Their results indicate that nucleotide 499 in the sequence of van Ormondt *et al.*[6] corresponds to the 5'-end of mRNAs from region E1A. Thus, the first 15 nucleotides of the 12S mRNA are missing from clone 133.

This investigation was supported by grants from the Swedish Cancer Society, the Swedish MRC and INSERM (U-163 Recombinaison et Expression Génétique). We thank Drs P. Tiollais, F. Rougeon and L. Philipson for helpful discussions, Dr H. Persson for preparation of early adenovirus mRNA and Dr T. Lindahl for polynucleotide kinase.

Inter- and intraspecific variation in restriction maps of *Drosophila* mitochondrial DNAs

D. M. Shah* & C. H. Langley

Laboratory of Animal Genetics, National Institute of Environmental Health Sciences, Research Triangle Park, North Carolina 27709

Mitochondrial (mt) DNAs have been observed to be polymorphic for cleavage sites of various restriction endonucleases[1–4]. Although these studies involved a variety of organisms, they were insufficient for the estimation of the level of genetic variation in natural populations. mtDNAs of various *Drosophila* species are heterogeneous in length, with molecular weights (MWs) ranging from 9.90 to 12.35×10^6. The mtDNA molecule of *Drosophila melanogaster* contains a long A+T-rich region representing 25% of the circle length[5,6]. A comparison of mtDNAs from different species of *Drosophila* by electron microscope partial denaturation mapping has shown that the size of the A+T-rich region varies among different species[5]. We have previously presented electron microscope heteroduplex analysis of the mtDNAs of *D. melanogaster*, *Drosophila simulans* and *Drosophila virilis* and showed that the sequence divergence was apparently greatest in the A+T-rich region, whereas the remainder of the molecule was much more evolutionarily conserved. The cleavage map of the *D. melanogaster* mtDNA molecule has been established using various restriction endonucleases[6–8]. The ribosomal RNA genes (rRNAs) and the A+T-rich region have been positioned on this map. We now present the restriction endonuclease maps of the mtDNAs of three species of *Drosophila*. We also report the results of a systematic survey of restriction site variation in the mtDNAs of natural populations of these species and make a preliminary comparison with the level of variation of nuclear genes. Our data suggest that the mitochondrial genome may evolve in a similar way to allozymic variation.

In this study, we have mapped the restriction sites in the mtDNA molecules of *D. virilis*, *D. melanogaster* and *D. simulans* using the enzymes *Eco*RI, *Hin*dIII and *Hpa*II. These enzymes make a small number of cuts in these mtDNAs and are therefore valuable in mapping the cleavage sites and in definitive identification of the conserved sites. mtDNAs were purified by

Fragment sizes are given in kilobases. The sizes of the fragments were determined from the agarose gels except as mentioned above. The sizes of *D. melanogaster* and *D. simulans* mtDNAs as determined by electron microscopy are 18.61 and 18.53 kilobases, respectively; that of *D. virilis* mtDNA is 15.86 kilobases. *D.m.*, *D.s.* and *D.v.* refer to *D. melanogaster, D. simulans* and *D. virilis* mtDNAs, respectively.

* Measured from polyacrylamide gels.

two cycles of CsCl–ethidium bromide centrifugation and digested with appropriate restriction endonucleases as described previously[7]. The sizes of the resulting fragments were determined from the calibrated agarose or polyacrylamide gels and by electron microscopy using ΦX174 replication form (RF) II DNA as an internal standard. Table 1 lists the sizes of the *Eco*RI, *Hin*dIII, *Hae*III and *Hpa*II restriction fragments of *Drosophila* mtDNAs. We have determined the relative positions of these restriction fragments on the mtDNA molecules by analysing the products of various double-enzyme digests. Thus, a total of 10 restriction sites were mapped on the *D. virilis* mtDNA molecule, whereas a total of 15 and 17 restriction sites were mapped on the mtDNA molecules of *D. melanogaster* and *D. simulans*, respectively. Figure 1 shows the cleavage maps of these mtDNAs. The cleavage maps of the *D. melanogaster* mtDNA molecule showing the positions of *Eco*RI, *Hin*dIII and *Hae*III sites have been reported previously[6,8]. Our map of *D. melanogaster* mtDNA molecule agrees with the published maps. The distribution of restriction sites is similar in two closely related species, *D. melanogaster* and *D. simulans*, but is markedly different in *D. virilis*, which is more distantly related to the other two species. *D. melanogaster* and *D. simulans* mtDNA molecules are similar in size[7] and share 11 restriction sites. The *D. virilis* mtDNA molecule is 2.75 kilobases shorter and shares only six restriction sites (see Fig. 1). One striking feature of *Drosophila* mtDNA maps is that four restriction sites proximal to the A+T-rich region are conserved in mtDNAs of all three species. Klukas and Dawid[6] have mapped mt-rRNA genes in this region of *D. melanogaster* mtDNA. It is therefore evident that the restriction sites within the rRNA genes of *Drosophila* mtDNAs are conserved. We have also mapped the A+T-rich region of each mtDNA molecule on the cleavage map by partial denaturation mapping and heteroduplex analysis of the *Hin*dIII and *Hae*III fragments of mtDNAs (see Fig. 1). It is evident that the relative positions of the A+T-rich regions are similar in mtDNA molecules of all three species. From the maps presented, it is clear that the A+T-rich region does not contain any restriction sites. *Alu*I, which recognises the sequence 5′ AGCT 3′, cuts *D. melanogaster* and *D. simulans* mtDNA molecules into approximately 18 fragments, but fails to cut the A+T-rich region. This region therefore contains little or no G and C. Using the maximum likelihood estimator of Kaplan *et al.*[9], we have estimated a 6% sequence divergence between *D. melanogaster* and *D. simulans* mtDNAs outside the A+T-rich region and the rRNA genes. However, the restriction map of *D. virilis* mtDNA is completely different from *D. melanogaster* and *D. simulans* mtDNAs outside the rRNA genes so that no further estimations could be made. However, some of the restriction sites surveyed might be appropriately modified in these native mtDNAs, leading to spurious conclusions concerning the presence of the sequence. In the absence of any direct evidence with respect to this question the analysis mentioned above and subsequent analysis of population data (below) cannot take it into account.

Ten isofemale lines of *D. melanogaster* were established simultaneously from a wild collection made in Raleigh, North Carolina, in 1977. Ten isofemale lines of *D. virilis* were also established from two collections made in Sapporo and Moji, Japan, in 1977 (five lines each). Five isofemale lines of *D. simulans* came from a collection made in Mishima, Japan, in 1977. The flies were cultured, the mtDNAs purified from the second and third instar larvae, and restriction sites mapped. Within each isofemale line mtDNA molecules always appeared homogeneous with respect to their restriction maps. Three variable sites were found among *D. melanogaster* lines (see Fig. 1). Figure 2*a* and *b* show the electrophoretic patterns of the restriction enzyme digest of different mtDNAs. These were

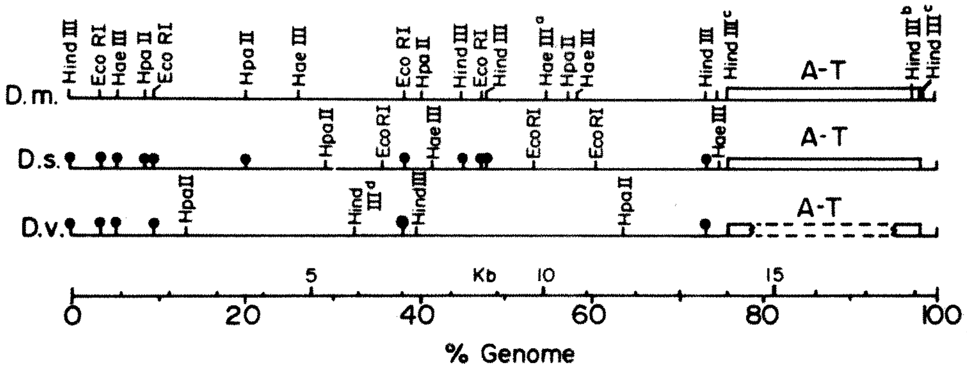

Fig. 1 The *Hin*dIII, *Hae*III, *Eco*RI and *Hpa*II restriction maps of *D. melanogaster* (*D.m.*), *D. simulans* (*D.s.*) and *D. virilis* (*D.v.*) mtDNAs. Units are % of genome and kilobases. Sites with superscripts are variable, as indicated in Fig. 3. The alternative positions of *Hin*dIII^{c} are indicated. *D. melanogaster* and *D. simulans* mtDNAs are 18.6 kilobase pairs in length. *D. virilis* mtDNA has 15.8 kilobase pairs. The reduction in the size of the A+T-rich region in *D. virilis* mtDNA has been indicated by broken lines (= = = =). ● Represents the restriction sites in *D. simulans* and *D. virilis* mtDNAs which are conserved in *D. melanogaster* mtDNA. Circular maps have been linearised to show the conserved restriction sites.

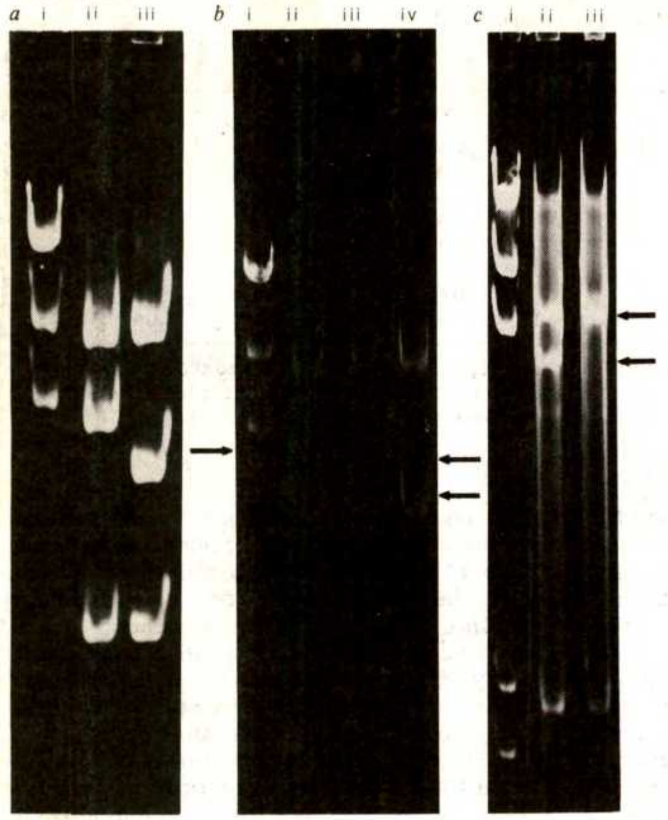

Fig. 2 Restriction analysis of *Drosophila* mtDNAs. *a*, 1.2% agarose gel of *Hin*dIII-digested λ DNA (i), *Hae*III-digested *D. melanogaster* mtDNA without *Hae*III^a site (ii) and with the *Hae*III^a site (iii). *b*, 1.2% agarose gel of *Hin*dIII-digested λ DNA (i), *Hin*dIII-digested *D. melanogaster* mtDNA without sites *Hin*dIII^b or *Hin*dIII^c (ii), with *Hin*dIII^b and without *Hin*dIII^c (iii) and with *Hin*dIII^c (iv). The lack of fluorescence of the middle band is probably due to long poly(dA)·poly(dT) segments. *c*, A 1.2% agarose gel of *Hin*dIII-digested λ DNA (i), *Hin*dIII-digested *D. virilis* mtDNA with the *Hin*dIII^d restriction site (ii) and without the *Hin*dIII^d site (iii). The gels were stained with ethidium bromide and photographed on Polaroid films using short-wave UV source.

distributed among the various lines as shown in Fig. 3*a*. The other variable site occurred among *D. virilis* lines as indicated in Figs 1 and 3*b*. Figure 2*c* shows the two *Hin*dIII patterns observed in *D. virilis*. The two sampling locations gave equal numbers of the two types of *D. virilis* mtDNA. No variation was observed among the lines of *D. simulans*.

Other than these data, the only information available on the intraspecific variability of *Drosophila* mtDNA restriction maps is from the 'standard' lines used in earlier studies. The standard line of *D. melanogaster* (D.m.1) used in our earlier work was collected in Raleigh, but 2 yr earlier than those reported above. The restriction map of this line for the four restriction enzymes is identical to that of the second most frequent class (see Fig. 3*a*). Restriction maps obtained by other laboratories on *D. melanogaster* mtDNA with *Hin*dIII, *Hae*III and *Eco*RI also fall into this class[6,8]. This mtDNA restriction map seems to be widespread and temporarily stable. The *D. virilis* line described in our previous studies[7] was also from Japan but collected 1 yr earlier in Fukuoka. We examined two lines from that collection, one of which had our standard and the other the variant pattern (Fig. 2*c*), suggesting temporal and geographical stability for this polymorphism. Finally, our *D. simulans* standard was derived from Raleigh, whereas our population sample (above) was collected several years later in Japan. The uniformity of the restriction maps in *D. simulans* is in striking contrast to the variability observed in *D. melanogaster*.

We can attempt to answer two questions with these results. The first concerns the significance of the interspecific differences in restriction map variability and the second compares the amount of variation in mtDNA and nuclear DNA. Unfortunately, there has been no systematic survey on the population level of restriction map variation in nuclear DNA. To investigate these matters, we must first determine a metric of restriction map variability that lends itself to analysis (the product of the population size and mutation rate).

Fundamentally, the population genetics of restriction maps is a special case of the 'finite sites model' (ref. 9). Also, the finite sites model is well approximated by the 'infinite alleles model' when the amount of variation relative to that possible is small[10]. Assuming the non-recurrent neutral mutation, finite population model[11] (infinite alleles model), we can estimate the pertinent parameter by two methods. If N_e is the effective population size (number of gene copies), and μ the mutation rate[11], either we can set $1/(2N_e\mu+1)$ equal to the 'expected homozygosity', that is, the sum of squared frequencies[11], or $2N_e\mu$ can be estimated by the maximum likelihood method of Ewens[12]. Estimates from these methods do not differ greatly (*D. melanogaster*, 3.6 or 2.0; *D. virilis*, 1.8 or 0.8; *D. simulans*, 0.0). When these values are tested using the sampling statistics of Ewens[12], the three species do not differ significantly.

To compare the mtDNA and allozyme data, each must be converted into a common unit of genetic variation. In our estimates of $2N_e\mu$, the mutation rate, μ, is the rate per generation of nucleotide changes that create new restriction sites or destroy pre-existing ones, that is, the rate of nucleotide substitutions that create new restriction maps. As pointed out above, if the extant variation is small (as it is in these cases) virtually all site changes will be new. If we assume a random nucleotide sequence and random mutation, the proportion of nucleotide substitutions that change restriction sites can be estimated[7]. In our case, it is 0.02 for the region of 12,000 base pairs excluding the A+T-rich DNA and that coding for the mt-rRNA. We exclude these regions because the A+T-rich region contains no restriction sites (GC content too low) and the rRNAs are much more conservative evolutionarily. On a per nucleotide basis, $2N_e\mu$ is then between 0.008 $[2.0/(0.02\times12{,}000)]$ and 0.0, with a mean of 0.003.

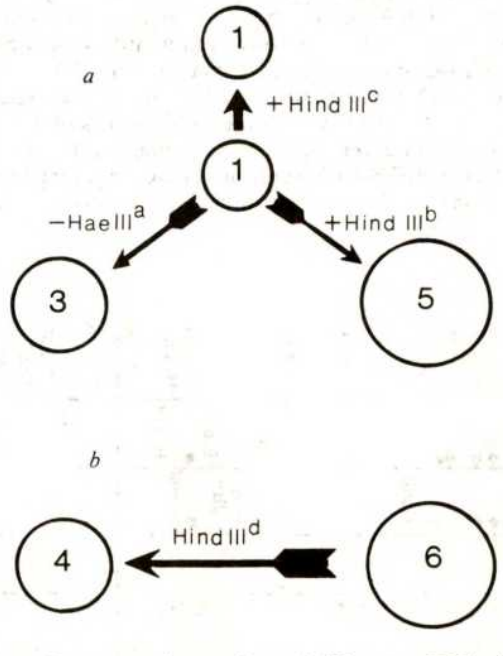

Fig. 3 *a* Represents the numbers of different mtDNAs found among the *D. melanogaster* isofemale lines and the substitutional paths between them. *b* Is a similar presentation of the mtDNAs of the *D. virilis* isofemale lines.

As there are no comparable estimates of restriction map variability in nuclear DNA, we must attempt to use electrophoretic data on population variability. Starting with an estimate of 0.04–0.14 for expected heterozygosity[13,14], we estimate $2N_e\mu$ to be 0.04–0.16 (ref. 11). If we assume that one-quarter of all nucleotide substitutions change the amino acid[15] and one-third of amino acid substitutions change the electrophoretic mobility, then μ in the above estimate is 0.08 of the total nucleotide mutation rate. Assuming 1,000 nucleotide positions per protein, this yields an estimate for $2N_e\mu$ of 0.0005–0.002 on a per nucleotide basis. Note that the electrophoretic techniques of detection of genic variation in proteins are more sensitive than the use of these four restriction enzymes (8% compared with 2% of the nucleotide substitutions). This is partly due to the low GC content of *Drosophila* mtDNAs.

Thus, we estimate $2N_e\mu$ for mtDNA at 0.003 (0–0.008) and for allozyme loci at 0.0005–0.002. Even considering the fact that N_e should be twice as large for nuclear (diploid) genes, there do not seem to be any significant differences in genetic variation between allozymes and mtDNAs. Whether this picture will survive more detailed scrutiny is unknown, but it seems likely that the quality of data on molecular genetic variation in natural populations will change significantly.

Structure of the region of the replication origin of the *Bacillus subtilis* chromosome

Motoharu Seiki, Naotake Ogasawara & Hiroshi Yoshikawa

Cancer Research Institute, Kanazawa University 13-1, Takaramachi, Kanazawa, 920, Japan

The chromosome of a Gram-positive bacterium, *Bacillus subtilis*, binds tightly to the cell membrane[1–3] probably through a DNA–protein–RNA complex formed specifically near the origin of replication[4,5]. Characterisation of this complex may reveal the role of the cell surface in regulating the initiation of DNA replication in bacteria. As a first step towards this goal, we have constructed a map of the restriction enzyme cleavage sites at the region of the origin of replication of the *B. subtilis* chromosome. Adopting the methodology originally used by Marsh and Worcel in *Escherichia coli*[6], the region of the origin of replication of the chromosome was labelled specifically with a radioisotope which was then used to characterise DNA fragments produced by various combinations of restriction enzyme. In the study reported here, cleavage sites by three enzymes were identified within the chromosomal fragment of molecular weight 4×10^7 at the origin region.

A thymine-requiring mutant of *B. subtilis*, CRK2000 (*trp, leu, thy*)[7], and its *ts-dna* mutant derivative, CRK2001 (*trp, leu, thy, din*^{ts})[8] which is defective in the initiation of DNA replication at 47 °C, were used to label the DNA at the origin of replication. Initiation of the replication cycle was synchronised either by germinating spores in the absence of thymine for at least 2 h or by incubating the ts-dna mutant cells at 47 °C for 1 h followed by incubation at 30 °C in the absence of thymine. In both cases addition of ^{3}H-thymidine (dThd) of high specific activity was assured to initiate chromosomal replication from the origin of replication and to label the origin region of the chromosome selectively[4]. The labelled DNA was purified and digested with

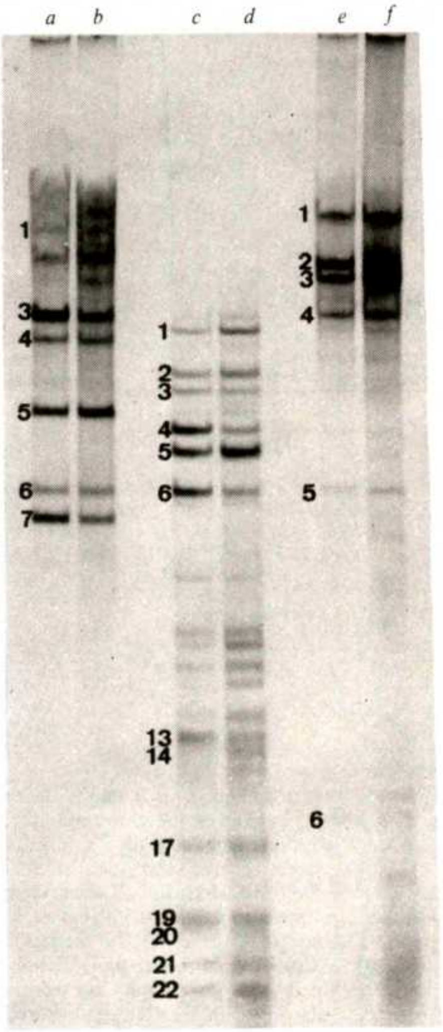

Fig. 1 Restriction endonuclease analysis of DNA, pulse labelled during the initiation of replication. Spores of *B. subtilis* CRK2000 (*leu, trp, thy*)[7] were germinated at 37 °C in a synthetic medium, GM11 (ref. 1), in the absence of thymine for 150 min, and then labelled with ^{3}H-dThd (Radiochemical Centre, Amersham), 10 μCi per 50 ng per ml, for 1 min (*b, d, f*). Novobiocin (Boehringer, Mannheim, 100 μg ml^{-1}) was added to a separate sample 5 min before the spores were labelled with ^{3}H-dThd for 8 min (*a, c, e*). Novobiocin reduced the rate of DNA replication to 7.5% of the control rate. The labelling was stopped by pouring the culture into an equal volume of ethanol–phenol (75% ethanol, 2% phenol in 21 mM Na-acetate buffer, *p*H 5.1, and 2 mM EDTA). Cells were collected by centrifugation, lysed with 1 mg ml^{-1} lysozyme in a lysis buffer (20 mM Tris-HCl, *p*H 8.1, 100 mM KCl, 1 mM EDTA) for 30 min and then treated with 1% Sarkosyl (Geigy) and 500 μg ml^{-1} pronase E (Kaken Kagaku). DNA was extracted and purified by repeating the phenol extraction and precipitation by ethanol in the lysis buffer. Purified DNA was digested wtih *Bam*HI (prepared as described previously[11]) (*a, b*), *Eco*RI (Miles) (*c, d*) or with *Sma*I (*e, f*) according to standard methods. Fragments were separated by electrophoresis in 0.7% agarose gel (Seakem) at 125 V for 16 h and detected by fluorography as reported by Marsh and Worcel[6].

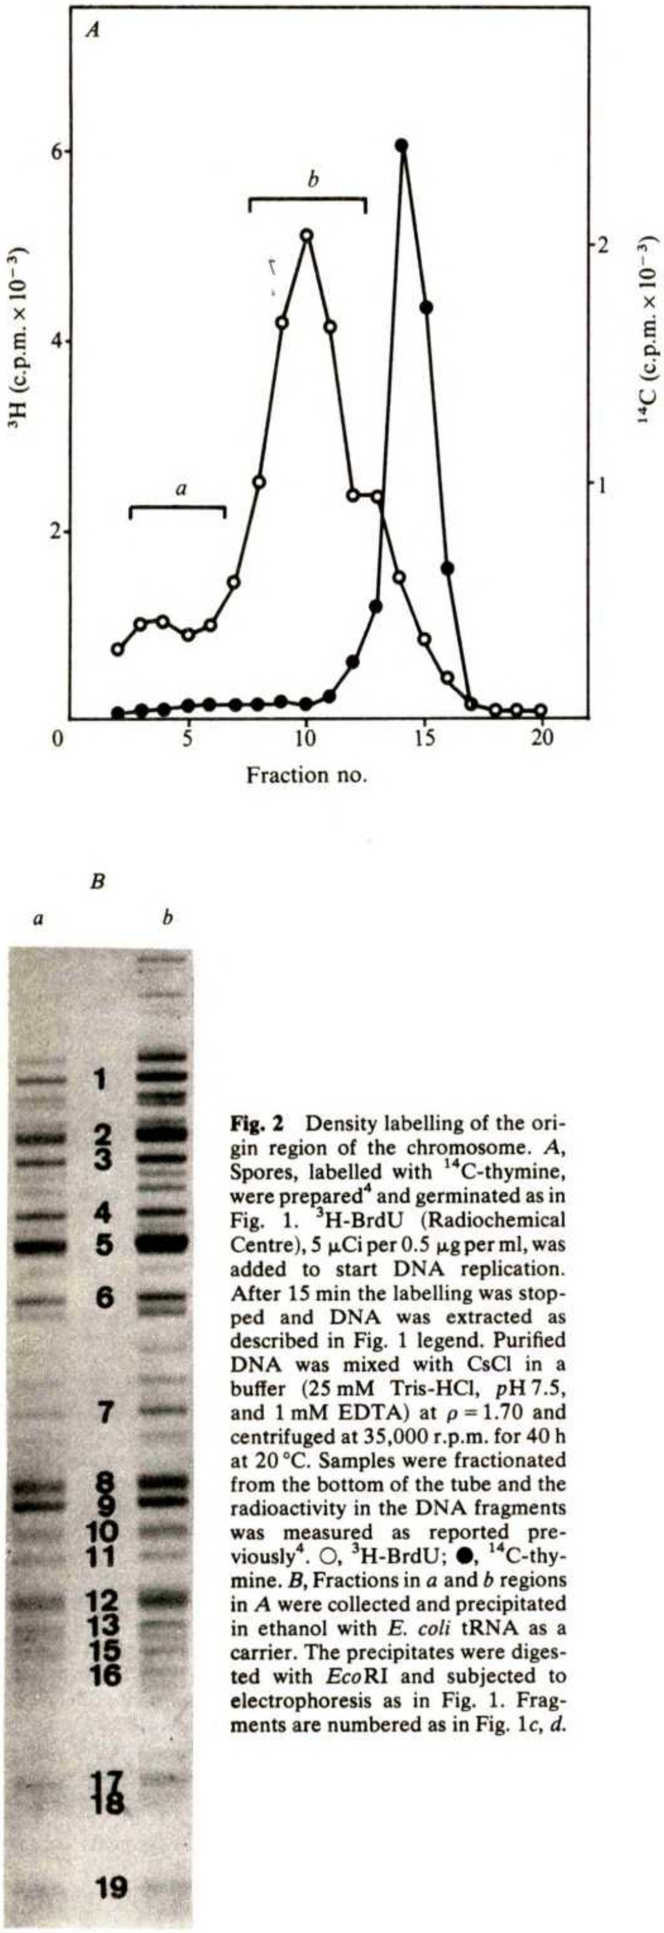

Fig. 2 Density labelling of the origin region of the chromosome. *A*, Spores, labelled with ^{14}C-thymine, were prepared[4] and germinated as in Fig. 1. ^{3}H-BrdU (Radiochemical Centre), 5 μCi per 0.5 μg per ml, was added to start DNA replication. After 15 min the labelling was stopped and DNA was extracted as described in Fig. 1 legend. Purified DNA was mixed with CsCl in a buffer (25 mM Tris-HCl, *p*H 7.5, and 1 mM EDTA) at $\rho = 1.70$ and centrifuged at 35,000 r.p.m. for 40 h at 20 °C. Samples were fractionated from the bottom of the tube and the radioactivity in the DNA fragments was measured as reported previously[4]. ○, ^{3}H-BrdU; ●, ^{14}C-thymine. *B*, Fractions in *a* and *b* regions in *A* were collected and precipitated in ethanol with *E. coli* tRNA as a carrier. The precipitates were digested with *Eco*RI and subjected to electrophoresis as in Fig. 1. Fragments are numbered as in Fig. 1*c*, *d*.

various restriction endonucleases, and the resultant ^{3}H-labelled fragments were analysed by agarose gel electrophoresis and fluorography.

Several discrete bands of fragments were detected in all enzyme digests. Figure 1 shows fragments produced by *Sma*I, *Eco*RI and *Bam*HI of the pulse-labelled DNA during synchronous initiation by germinating spores. The number of detectable bands increased with the length of the labelling period (details of the time course are reported in the accompanying paper[9]). Essentially identical fragment patterns were obtained when DNA was labelled during the synchronous initiation by *ts-dna* mutant (data not shown). To confirm that the label was incorporated by semi-conservative replication and not by a repair-type synthesis, ^{3}H-bromodeoxyuridine (BrdU) was added in place of ^{3}H-dThd to the germinating spores. A completely replicated DNA was collected by CsCl equilibrium density centrifugation and its restriction enzyme fragments were analysed. Figure 2 shows that (1) a short pulse with ^{3}H-BrdU resulted in a density shift, indicating semi-conservative replication, and (2) ^{3}H-BrdU-labelled fragments of the *Eco*RI digest were identical to those of ^{3}H-dThd-labelled DNA.

Major bands of Fig. 1 were used for further analysis to construct the cleavage map. Each band produced by one enzyme was extracted, purified and then digested with the other two enzymes to make a thorough comparison between the three groups of fragments. Results of the analysis are summarised in Table 1 and a map of cleavage sites was constructed and is shown in Fig. 3. First, the relative location of fragments S6 and S2 were determined because fragment B3 overlapped these two *Sma*I fragments. As most of fragment B5 was derived from fragment S2, fragments B3 and B5 must be contiguous to each other. The third and largest *Sma*I fragment, S1, contained one *Bam*HI site, thus producing two *Bam*HI fragments, B1 and the major portion of B7. When fragment B7 was digested by *Sma*I three fragments were produced. The largest of these, of MW 2.85×10^{6}, corresponded to one of the two *Bam*HI fragments derived from S1, whereas the smallest fragment, of MW 0.2×10^{6}, corresponded to the smaller one of the two fragments derived from fragment S6 by *Bam*HI digestion. These results indicated that fragments S1 and S6 were contiguous to each other, with a fragment of 0.5×10^{6} MW inserted between them. Therefore, the relative locations of the *Sma*I fragments are S1–0.5×10^{6} MW fragment–S6–S2. From this result the order of the *Bam*HI fragments was deduced as B1–B7–B3–B5.

Once the cleavage sites of *Sma*I and *Bam*HI were mapped, *Eco*RI sites could be assigned as follows. Fragments E4 and E22 could be assigned as they were derived from one of the four *Bam*HI fragments and contained *Sma*I sites. In the same way fragments E6, E17 and E27 were located because they were derived from one of the three *Sma*I fragments and contained one *Bam*HI site. The space between fragments E6 and E22 matched precisely with E19, which is derived from fragment B7. Fragment E13 was located between E4 and E17 in the same manner. Fragments E5 and E20 can be mapped at any place within fragment B1. However, we set these fragments as contiguous to E6 because they were replicated much earlier than fragment E1. Relative positions of fragments E14, E21 and E26, all derived from B5, have not been determined. One of the major early replicating *Sma*I fragments, S3, whose *Bam*HI and *Eco*RI sites have been mapped as in Fig. 3, is most probably located close to S2. Assuming B5 and B6 to be contiguous to each other, there will be an additional *Sam*I fragment of MW $\sim 1.8 \times 10^{6}$, containing one *Bam*HI site, situated between fragments S2 and S3. A fragment of the corresponding MW can be seen above fragment S6 in Fig. 1. Therefore, it is most likely that fragments B5 and B6 are contiguous and so the map in Fig. 3 can be drawn continuously. However we cannot be certain of this until the additional, small *Sma*I fragment is fully characterised. The origin of replication is located within fragment B7, as described in the accompanying paper.

We have reported recently that a DNA segment near the origin of replication formed a specific complex (S-complex) with

Table 1 Results of enzyme analysis

Fragment numbers are the same as those in Fig. 1. Each fragment was cut out from the gel and DNA was extracted with 4 M KI and purified by passing through a hydroxyapatite column as reported previously[10]. Each DNA sample was then digested with the other two enzymes and analysed by the same electrophoresis method as described in Fig. 1 legend. The MW of each fragment was determined by making parallel electrophoretic runs for ^{3}H-labelled standard fragments of known MW (*Eco*RI and *Hin*dIII digests of λ DNA). Id (indigestible) indicates that the fragment did not contain sites cleaved by the second enzyme concerned. ND, Not determined. By comparing each pair of doubly digested fragments of the same enzyme combinations but in reverse order, we determined the second source of fragment to which a given fragment belongs; these are indicated in parentheses.

*Fragments assumed to occur in the electrophoresis but not detected in the conditions used.

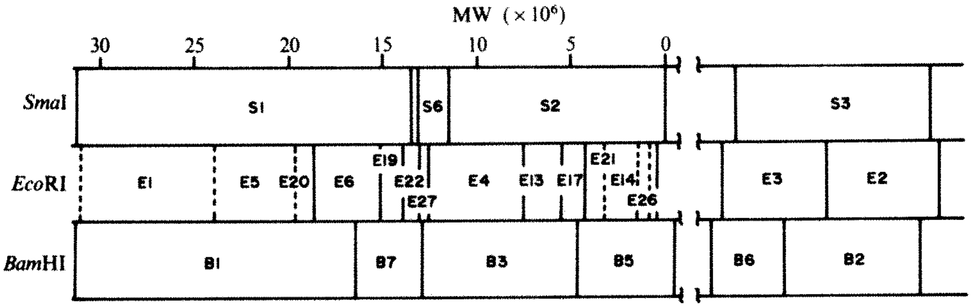

Fig. 3 A map of restriction enzyme cleavage sites near the origin of replication. Relative location of the fragments in Fig. 1 and Table 1 were determined as discussed in the text. To indicate the MW of the fragments, the right hand edge of the *Sma*I-2 fragment was taken as a reference point.

proteins and RNA[3,4]. Asymmetric location of the DNA fragments in the S-complex at one side of the replication origin was assumed by comparing restriction enzyme fragments of this DNA with those of the pulse-labelled DNA at the region of the origin of replication[4,5]. The present mapping data are consistent with the asymmetric location of the S-complex. Judging from the size of the fragments, there are homologues of the E1 and E5 fragments in the DNA from the S-complex, while no fragments to the right hand side of E20 have homologues in the complex DNA. This result is also consistent with the genetic evidence for the asymmetric association of the origin region of the *B. subtilis* chromosome with the cell membrane[3,4].

We thank Dr S. Murakami and other colleagues in our laboratory for discussions and Mrs K. Terada and Miss K. Ando for their help. *Sma*I was provided by Dr Y. Kajiro. This work was supported by grants-in-aid for scientific research and for cancer research from the Ministry of Education, Science and Culture, Japan.

Effect of novobiocin on initiation of DNA replication in *Bacillus subtilis*

Naotake Ogasawara, Motoharu Seiki & Hiroshi Yoshikawa

Cancer Research Institute, Kanazawa University 13-1, Takaramachi, Kanazawa 920, Japan

The initiation of DNA replication of small replicons *in vitro* involves conformational changes in the whole DNA molecule or in the region near to the replication origin[1–4]. One striking finding has been the role of DNA gyrase (that is, the necessity for supercoiled structure) in the initial stage of ColE1 replication *in vitro*[5,6]. However, little is known about the effect of gyrase on the initiation of replication of bacterial chromosomes *in vivo*. We have constructed a map of cleavage sites of restriction enzymes at the region of the origin of replication of the *Bacillus subtilis* chromosome (accompanying paper[7]). This has now enabled us to examine the effect of novobiocin, a selective inhibitor of DNA gyrase[8], on the replication of the specific chromosomal segments near the origin and to seek a possible role for the gyrase in the initiation of chromosomal replication. We have found that only a limited segment of the chromosome at the origin region was replicated in the presence of novobiocin. This effect allowed us to locate the site of the origin of replication to within a DNA fragment of molecular weight 3.4×10^6.

We used a spore germination of a thymine-requiring mutant of *B. subtilis*, CRK2000 (*leu*, *trp*, *thy*)[9], to synchronise the initiation of replication. The mutant spores were germinated in a synthetic medium, GM11 (ref. 10), in the absence of thymine for 150 min; ^{3}H-thymidine (dThd) was then added to initiate replication synchronously.

Figure 1 shows that replication started immediately after the addition of dThd. Therefore, the region which was labelled early probably contained the region of the origin of replication. When novobiocin was added at various concentrations 60 min before dThd, DNA replication was markedly inhibited, in a manner dependent on the inhibitors concentration. At each concentration replication proceeded linearly at reduced rates. When novobiocin was added at various times during the thymine-free germination and thymidine added later at the 150th min to all samples, varied effects of the drug were observed. Figure 1*b* shows that the initiation of replication was further reduced when novobiocin was added during the first 45–50 min after the onset of germination. After 45–50 min the reduced rates became fairly constant, depending only on the novobiocin concentration. As DNA replication was initiated synchronously at the 45–50th min during germination in the presence of thymidine, the initiation potential (the cell's ability to initiate replication) was assumed to be formed during the first 45 min. Data in Fig. 1*b* suggest an inhibitory effect of novobiocin on the formation of the initiation potential during germination.

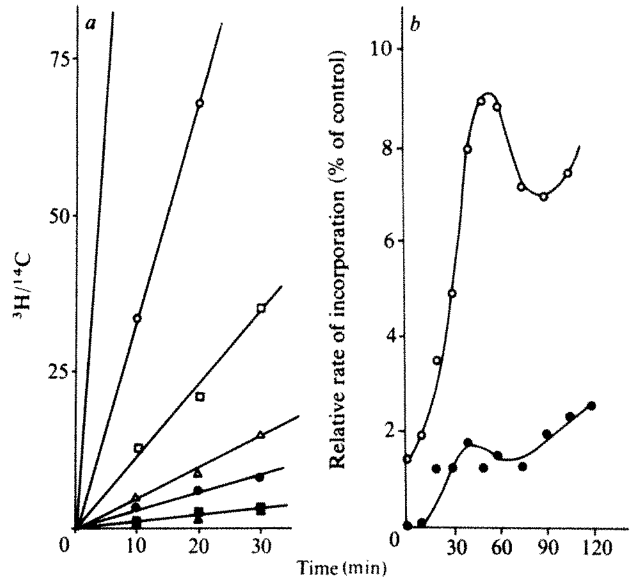

Fig. 1 The initiation of DNA replication in the presence of novobiocin. *a*, spores of *B. subtilis* CRK2000 (*leu*, *trp*, *thy*)[9] were labelled with ^{14}C-thymine as reported previously[9]. The labelled spores were germinated in a synthetic medium GM11 (ref. 10), in the absence of thymine after heat activation at 80 °C for 15 min. After 90 min, novobiocin (Boehringer Mannheim) was added at various concentrations and at the 150th min ^{3}H-dThd (Radiochemical Centre, Amersham), 5 μCi per 75 ng per ml, was added to initiate DNA replication. Thereafter, 1.0-ml samples were taken at the times indicated and precipitated in 10% trichloracetic acid after incubation in 0.2 M KOH for 30 min at 80 °C. The precipitates were collected on a glass fibre filter and radioactivity were measured in a Beckman scintillation counter LS7000. Incorporation of ^{3}H-dThd was normalised by ^{14}C-activity in the spore. –, No drug; –○–, 2.5 μg ml^{-1}; –□–, 5 μg ml^{-1}; –△–, 7.5 μg ml^{-1}; –●–, 10 μg ml^{-1}; –■–, 20 μg ml^{-1}; –▲–, 40 μg ml^{-1} novobiocin. *b*, The ^{14}C-labelled spores were germinated as in *a* except that novobiocin was added at various times during the thymine-free germination. ^{3}H-dThd, 5 μCi per 75 ng per ml, was added to all samples at the 150th min. The rate of incorporation was measured for each sample from the slope of linear incorporation as in *a*. It was then normalised by the initial rate of the control sample and plotted against the time of novobiocin addition. –○–, 5 μg ml^{-1}; –●–, 10 μg ml^{-1} novobiocin.

To examine the nature of this reduced replication in the presence of novobiocin, chromosomal segments which were replicated in the presence of novobiocin were identified by digesting ^{3}H-labelled DNA with restriction endonucleases and then analysing the resulting fragments by agarose gel electrophoresis and fluorography. Figure 2 shows that only a limited number of *Eco*RI fragments were labelled when 10 μg ml^{-1} novobiocin was used. The number of labelled fragments increased more slowly with the lower concentration, 5 μg ml^{-1}. The quantitative measurement of the label in each fragment is shown in Fig. 3*A*, which indicates that fragments were labelled in a definite order in the presence of novobiocin. Thus, fragment E19 was the first to be labelled, followed by fragments E22, E27, E6, E20, E5 and so on. Identical results were obtained with *Bam*HI fragments. Figure 2 also shows that fragment B7, which contained fragment E19, was replicated first, followed by fragments B3 and B5.

Comparing these results with the map of the restriction sites near the origin of replication (see accompanying paper), we estimated time courses of initiation and replication in the presence and absence of novobiocin. The results demonstrated a bidirectional replication starting within fragment B7. Furthermore, it shows clearly that only a limited region around the origin was replicated in the presence of 10 μg ml^{-1} novobiocin. The remarkably high level of incorporation into fragments E19 and E22 was not due to a premature re-initiation, because chloramphenicol had no effect on this level when added 60 min before the isotope. This indicates that some cells replicated to lengths of only $1.0–1.5 \times 10^6$ MW in the presence of the drug. When germinating spores were labelled for short times in the absence of novobiocin, the labelling patterns obtained were essentially the same as those with novobiocin. However, the rate of elongation was too fast to determine the labelling sequence among early replicating fragments other than fragments E19, E22 and E27 (Fig. 3). The unusually high level of labelling in fragment E5 might have been due to its contamination by one or two other fragments which were not replicated in the presence of novobiocin. This is further suggested by the finding that a part of fragment E5 from the control sample was digested by *Bam*HI, whereas fragment E5 from the novobiocin sample had no *Bam*HI site. Also, in certain conditions, the control fragment E5 split into two or more bands.

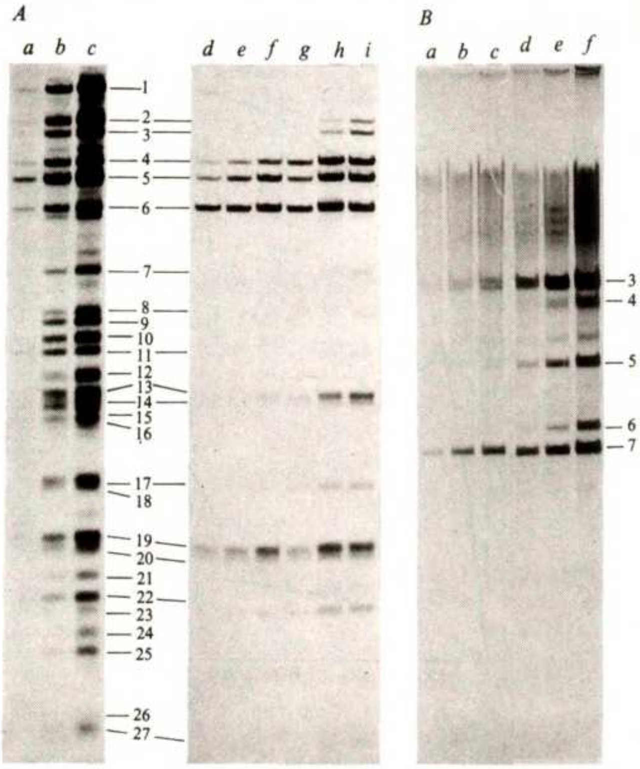

Fig. 2 Analysis by restriction endonucleases of DNA, pulse labelled during the initiation of replication in the presence of novobiocin. Spores were germinated as in Fig. 1. Novobiocin and ^{3}H-dThd, 10 μCi per 50 ng per ml, were added at the 90th and 150th min, respectively. The labelling was stopped by pouring the culture into an equal volume of ethanol–phenol (75% ethanol, 2% phenol in 21 mM Na-acetate buffer, *p*H 5.1, and 2 mM EDTA). Cells were collected by centrifugation, lysed with 1 mg ml^{-1} lysozyme in a lysis buffer (20 mM Tris-HCl, *p*H 8.1, 100 mM KCl, 1 mM EDTA) for 30 min and then treated with 1% Sarkosyl (Geigy) and 500 μg ml^{-1} pronase E (Kaken Kagaku). DNA was purified by repeating the phenol extraction and precipitation by ethanol in the lysis buffer. The purified DNA was digested with *Eco*RI (Miles) or *Bam*HI (prepared as reported previously[11]) using standard methods, and subjected to electrophoresis in 0.7% agarose gel and detected by fluorography as described by Marsh and Worcel[12]. *A*, The patterns for *Eco*RI digests. *a–c* Are DNA samples labelled for 45, 90 and 135 s, respectively, without the drug. *d–f* Are DNA samples labelled for 10, 20 and 30 min with 10 μg ml^{-1} novobiocin. *g–i* Are DNA samples labelled for 10, 20 and 30 min with 5 μg ml^{-1} novobiocin. *B*, The patterns for *Bam*HI digests. *a–c* Are samples labelled for 5, 10 and 15 min with 10 μg ml^{-1} novobiocin. *d–f* Are samples labelled for 5, 10 and 15 min with 5 μg ml^{-1} novobiocin.

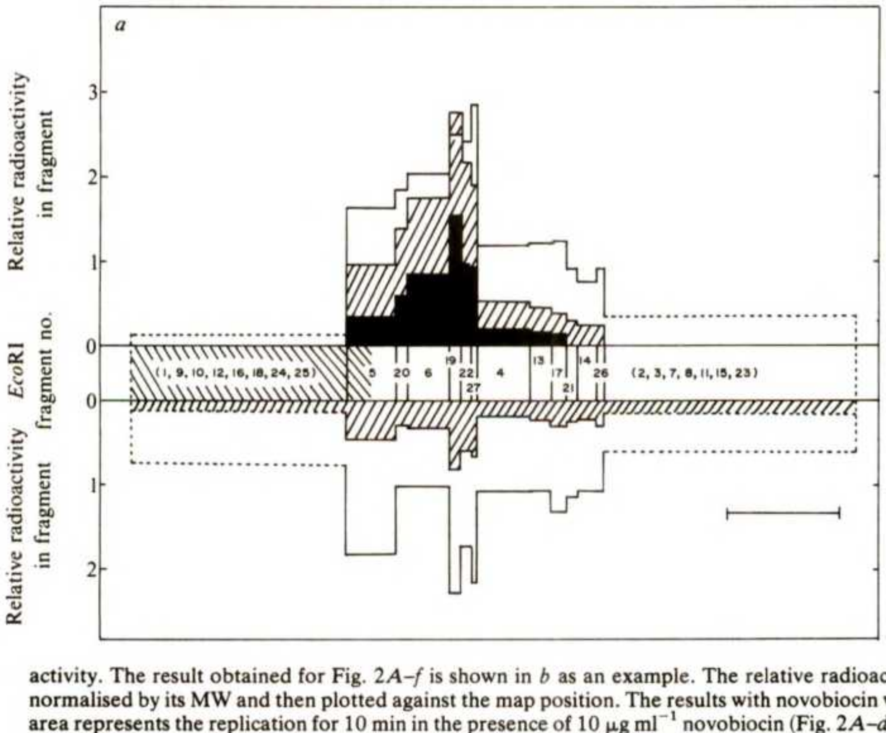
The experimental results presented here indicate that novobiocin had two types of effect on DNA replication. First, it inhibited formation of the cell's potential ability to initiate DNA replication. This may be a direct effect on DNA structure or it may act indirectly through inhibition of RNA synthesis. Second, it permitted a limited amount of replication at a specific segment of the chromosome near the origin of replication, once the initiation potential had been formed in the cell.

These results suggest that the conformational changes in the chromosome, due in part to the function of DNA gyrase, is essential both for initiation and for further elongation even after the proper conformation has been formed in the cell. These effects of novobiocin on chromosomal replication resemble those of gyrase on *in vitro* replication of ColE1 plasmid[5,6].

We thank Dr S. Murakami and other colleagues in our laboratory for discussions and Mrs K. Terada and Miss K. Ando for their help. This work was supported by grants-in-aid for scientific research and for cancer research from the Ministry of Education, Science and Culture, Japan.



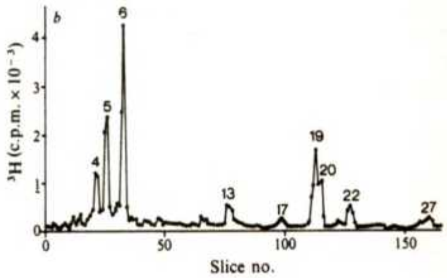


Fig. 3 *a*, A schematic representation of the time course of replication in the presence or absence of novobiocin. The *Eco*RI fragments numbered in Fig. 2*A* were linearly arranged according to the map for restriction enzyme cleavage sites near the origin of replication. The fragments outside E5 and E26 were divided into two groups depending on whether or not a given fragment found its homologue in the DNA in the S-complex[13,14]. Relative locations in each group have not been determined. The hatched area on the map shows the location of the DNA in the S-complex[13,14]. Each agarose gel in Fig. 2*A* was cut in strips 1 mm wide and put in a scintillation mixture to measure ^{3}H activity. The result obtained for Fig. 2*A–f* is shown in *b* as an example. The relative radioactivity under the area of each fragment peak was normalised by its MW and then plotted against the map position. The results with novobiocin were drawn above the fragment map. The shaded area represents the replication for 10 min in the presence of 10 μg ml^{-1} novobiocin (Fig. 2*A–d*). The hatched area represents the replication for 30 min with 10 μg ml^{-1} novobiocin (Fig. 2*A–f*). The open area represents the replication for 30 min with 5 μg ml^{-1} novobiocin (Fig. 2*A–i*). Control samples are shown below the map. The hatched area represents the replication for 45 s (Fig. 2*A–a*) and the open area replication for 90 s (Fig. 2*A*(*b*) both in the absence of novobiocin. The dotted line shows the average radioactivities within the group of fragments shown in parentheses.

Ribonucleotides in DNA newly synthesised in 3T6 cells *in vivo*

Jacek Kowalski & David T. Denhardt

Department of Biochemistry, McIntyre Medical Sciences Building, McGill University, 3655 Drummond Street, Montreal, Quebec, Canada H3G 1Y6

Within the field of DNA replication, considerable interest has focused in recent years on the mechanism of initiation of synthesis of DNA molecules. *In vitro* replication systems from *Escherichia coli* have been instrumental in uncovering a priming function for ribonucleotides on the earliest intermediates of DNA polymerisation *in vitro* and in identifying the proteins involved[1-3]. *In vitro* replication systems from mammalian cells that permit the use of the phosphate-transfer method for detection of RNA-DNA junctions as well as direct labelling of the RNA moiety of the molecules have suggested a similar role for ribonucleotides in DNA synthesis in eukaryotes[4-8]. However, the existence of this mechanism in mammalian cells *in vivo* has not been established. Here we report the first evidence that a significant proportion of the earliest intermediates in mammalian DNA polymerisation *in vivo* do, in fact, possess ribonucleotides, presumably because their synthesis was initiated with one or more ribonucleotides.

In *E. coli* several types of experiment have been carried out with nascent DNA from intact cells. The direct approach uses purification of nascent DNA molecules, labelling of their 5'-ends with ^{32}P using polynucleotide kinase, and subsequent demonstration of the release of 2'(3'), 5'-[^{32}P]-ribonucleoside diphosphates on alkaline hydrolysis[9]. We used this approach to study DNA synthesis in mammalian cells, and found that, in addition to difficulties due to the presence of contaminating RNA molecules not covalently attached to DNA, the presence of a large number of small non-nascent DNA molecules of uncertain origin obscured an adequate demonstration of ribonucleotides at the 5'-ends of nascent molecules[10,11]. An alternative approach involves alkaline hydrolysis of nascent DNA molecules phosphorylated at the 5'-end with polynucleotide kinase. The appearance of 5'-OH termini, on alkaline hydrolysis of the nascent polynucleotide is assayed by labelling with ^{32}P using polynucleotide kinase[9,12], or by digestion of the molecules with the 5'-OH-specific exonuclease, spleen phosphodiesterase[9,13]. In *E. coli*, there is good evidence that some of the nascent DNA molecules are initiated with ribonucleotides *in vivo*. *Physarum* is the only eukaryote in which evidence (by phosphate transfer) for RNA priming *in vivo* has been obtained[14]. Earlier experiments using differences in buoyant density as a measure of covalent linkage of RNA to nascent DNA[15,16] have been shown to be subject to artefact[17]. We have examined nascent DNA molecules synthesised in intact murine 3T6 cells for the presence of ribonucleotides by the method which uses spleen exonuclease.

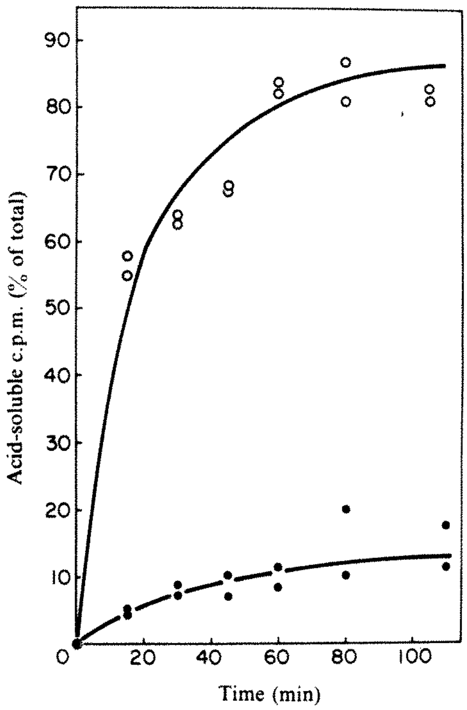

Fig. 1 Time course of digestion of DNA by spleen exonuclease. DNA uniformly labelled with ^3H-dThd and extracted from 3T6 cells with SDS was deproteinised by phenol–chloroform extraction. Heat-denatured DNA was separated from RNA by chromatography on nitrocellulose[10]. The material was then sonicated extensively and fractionated on a neutral sucrose gradient. Fractions containing DNA 1,200–2,400 nucleotides long were pooled. After re-precipitation with isopropanol the DNA (300 nmol nucleotide per ml in 50 mM Tris-Cl, *p*H 8) was heat denatured. One half was incubated with bacterial alkaline phosphatase purified as previously described[9] at a concentration of 1 unit ml^{-1} at 65 °C for 1 h. The other half was exposed to T4 polynucleotide kinase (purified as previously described[9]) and ATP in 50 mM Tris-Cl (*p*H 8.1), 2 mM potassium phosphate, 10 mM $MgCl_2$ and 20 mM 2-mercaptoethanol for 60 min at 25 °C. The amount of ATP required in the reaction mixture was determined by estimating the number of 5'-ends from the concentration of nucleotide and the size of the DNA. ATP was added in a 500-fold molar excess over the number of 5'-ends in the sample. Both kinase and phosphatase-treated portions were then made 20 mM in EDTA, 100 mM in NaCl and 30 μg ml^{-1} in SDS extracted once with phenol–chloroform (1:1) and precipitated with isopropanol. DNA redissolved in water was adjusted to the following conditions: 150 mM CH_3COONa (*p*H 5.5), 10 mM EDTA, 50 mM Na_2SO_4, 30–100 μg ml^{-1} DNA. The DNA was heated at 100 °C for 20 s. Spleen exonuclease, purified as described by Bernardi and Bernardi[18], was then added to a concentration of 33 μg ml^{-1} and incubated with the DNA at 45 °C for the time indicated. Each incubation, in duplicate, was then made 400 μg ml^{-1} in salmon sperm DNA and 10% in trichloroacetic acid. After 20 min at 4 °C, it was centrifuged at 16,000*g* for 10 min. The precipitate was washed once with 10% trichloroacetic acid and redissolved in 0.2 M NaOH at 100 °C. Radioactivity in the supernatant and precipitate was determined in an aqueous scintillation counting cocktail after neutralisation. ○, Phosphatase-treated DNA; ●, kinase-treated DNA.

Spleen exonuclease was purified from porcine spleen by the procedure described by Bernardi and Bernardi[18]. The specificity of the enzyme for 5'-OH-terminated DNA is shown in Fig. 1. The maximal extent of digestion of 5'-OH DNA was 85-90%. The enzyme shows a marked preference for single-stranded molecules[18] and the residual resistance is probably due to the presence of secondary structure in the DNA. In these conditions 5'-phosphoryl DNA was degraded to the extent of about 15%. We suspect that this is the result of the presence of small amounts of endonuclease in the exonuclease preparation[19,20]. About 10% of circular single-stranded bacteriophage ΦX174 DNA was degraded to mononucleotides by the enzyme in 60 min (1 μg ml^{-1} ^{32}P-labelled ΦX DNA + 100 μg ml^{-1} denatured salmon sperm DNA + 33 μg ml^{-1} enzyme; other conditions as in Fig. 1). The 3T6 cell DNA preparations were not contaminated by endonuclease activity as the rate of digestion by spleen exonuclease of phosphatase- or kinase-treated DNA (Fig. 1) was unchanged by preincubation of the DNA for 8 h at 37 °C or for 1 h at 45 °C (data not shown). Other experiments

Table 1 Per cent digestion by spleen exonuclease of pulse-labelled and pulse-chase-labelled DNA after alkali or phosphatase treatment

DNA	Size class	Treatment before spleen exonuclease: None	Alkali	Phosphatase
^{3}H-Pulse	*a*	9.5	25	50
^{3}H-Pulse-chase	*a*	5.0	5.0	38
^{32}P-Uniformly labelled	*a*	8.8±0.3	4.7±0.2	43±0.3
^{3}H-Pulse	*b*	8.8	23	53
^{3}H-Pulse-chase	*b*	4.5	4.3	43
^{32}P-Uniformly labelled	*b*	5.0±0.5	3.7±0.2	44±1
^{3}H-Pulse	*c*	18	36	78
^{3}H-Pulse-chase	*c*	8.5	5.8	75
^{32}P-Uniformly labelled	*c*	7.3±0.2	5.0±0.8	69±1

^{3}H-DNA, labelled briefly (pulse) or (see text) for several hours (pulse-chase), was mixed with control ^{32}P-DNA of the appropriate size as indicated in Fig. 2 legend and treated with polynucleotide kinase and ATP in the conditions described in Fig. 1 legend. Each sample was then divided into three portions. One portion was adjusted to 0.4 M NaOH and all three were incubated at 37 °C for 8 h. The alkaline portion was neutralised and one of the two portions not exposed to alkali was treated with phosphatase. DNA in all three samples was extracted with phenol–chloroform as described in Fig. 1 legend and precipitated. All samples were then incubated with spleen exonuclease for 20 min in the conditions described in Fig. 1 legend. Each determination of acid-soluble and acid-insoluble radioactivity involved 5–50×10^3 c.p.m. each of ^{32}P and ^{3}H. The values for digestion of ^{32}P-uniformly labelled DNA accompanying the two ^{3}H-labelled preparations (pulse and pulse-chase) have been averaged and the standard error is indicated.

(not shown) indicated that the extent of digestion of DNA varied with the enzyme concentration, reaching a plateau at 25 μg ml^{-1}. The rate of digestion was tested at different substrate concentrations and was found to be constant in the range 30–200 μg ml^{-1} of DNA. Thus, all digestions with spleen exonuclease were carried out for 20 min at 45 °C with 33 μg ml^{-1} of enzyme and 30–100 μg ml^{-1} of substrate.

DNA synthesised by cultures of 3T6 cells was labelled with ^{3}H-thymidine (^{3}H-dThd) for 1 min at 37 °C after 5 min at 4 °C to allow equilibration of intracellular precursor pools. In some cultures DNA synthesis was abruptly stopped by lysis of the cells with SDS at 100 °C (ref. 10) whereas other cultures were incubated in the presence of unlabelled dThd for an additional 2 h. All lysates were briefly sonicated to fragment the high molecular weight DNA. The preparation was deproteinised by treatment with Pronase and extraction with phenol–chloroform and RNA was separated from DNA by chromatography on nitrocellulose. Sonicated ^{32}P-labelled 3T6 cell DNA was added to the ^{3}H-dThd-labelled preparations to serve as an internal control for all subsequent analyses. The DNA was fractionated into three classes by centrifugation in neutral sucrose density gradients, as shown for the pulse-labelled DNA in Fig. 2. The size of the DNA in pools *a*, *b* and *c* estimated from the sedimentation constants was 4–15, 0.2–4 and <0.2 kilobases respectively. This DNA was then reacted with polynucleotide kinase and enough ATP to give a 500-fold molar excess of ATP over the number of 5′-ends in the sample. Aliquots of the preparation were subjected to alkaline hydrolysis or alkaline phosphatase treatment. The DNA was then tested for spleen exonuclease sensitivity as described above. Immediately before each step in this purification and before all enzyme treatments, the DNA was heated to 100 °C for 20 s. The results of a typical experiment are shown in Table 1.

Treatment of DNA with alkali results in a significantly increased sensitivity to spleen exonuclease digestion in pulse-labelled DNA that is absent in pulse-chase-labelled DNA and in the internal control. We interpret these data to mean that nascent DNA molecules contain ribonucleotides. However, spleen exonuclease sensitivity after alkali treatment alone is indicative of an alkali-labile structure in the molecule, not necessarily a ribonucleotide. The results of four additional experiments on separate preparations of pulse-labelled DNA are summarised in Table 2.

The background levels of spleen exonuclease sensitivity in these experiments are slightly higher than those for the experiment shown in Table 1. The background level of digestion of ^{3}H-pulse-labelled untreated DNA averaged 30%. Treatment with either alkali or ribonuclease before spleen exonuclease increased this to an average of 40%. The greatest increase (18%) was observed with the smallest molecules (size class *c*), the least increase (3%) with the largest molecules (size class *a*). The background digestion of uniformly ^{32}P-labelled DNA averaged 16%. Alkali or ribonuclease treatment increased this average by only 2%. The fact that ribonuclease acts in a manner quantitatively identical to alkali strongly suggests that the increase in sensitivity is due to the presence of ribonucleotides.

Not all the molecules contained ribonucleotides. The maximum extent of spleen exonuclease sensitivity in a 20-min incubation with the enzyme is demonstrated by the samples treated with phosphatase. The resistance to digestion by spleen exonuclease increases with the size of the molecules, probably because the likelihood of the enzyme encountering secondary structure in the DNA also increases. The increase in sensitivity due to alkali or ribonuclease as a proportion of the increase due to phosphatase allows an estimation of the fraction of nascent molecules that possess ribonucleotides. In this manner we estimate from Table 2 that 13%, 27% and 42% of the molecules in size classes *a*, *b* and *c*, respectively, contain ribonucleotides. Thus, the presence of ribonucleotides on the smallest, and presumably most nascent, molecules extends the observations in Table 1 that pulse-labelled, but not pulse-labelled and chased, molecules seemed in part to contain ribonucleotides. Knowing the size of the molecules and assuming that the ^{3}H is uniformly distributed within them, we estimate that 96% of the molecules are in class *c*, so that about 40% of all nascent molecules possess ribonucleotides. This agrees reasonably well with previous studies by other methods on the proportion of Okazaki pieces

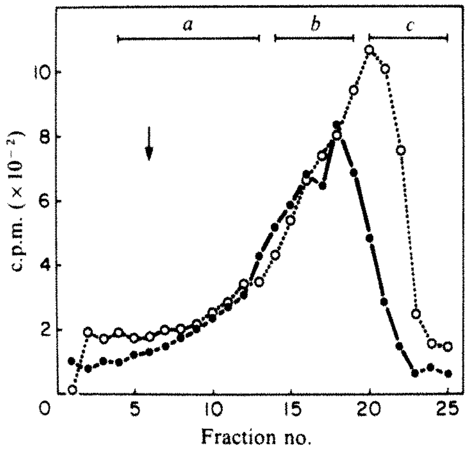

Fig. 2 Neutral sucrose gradient fractionation of ^{3}H-pulse-labelled DNA and uniformly ^{32}P-labelled DNA. 3T6 cells grown to confluence in 5% serum were partially synchronised by replating in 10% serum 24 h before labelling[24]. Cell cultures in plates were floated in an ice bath at 4 °C and exposed to 500 μCi ml^{-1} (60 Ci mmol^{-1}) ^{3}H-dThd in culture medium at 4 °C for 5 min. The plate was then floated in a 37 °C water bath and an equal volume of culture medium at 37 °C containing 500 μCi ml^{-1} ^{3}H-dThd was added to the plate. We find that this method of pre-equilibration with dThd[25] results in the incorporation of two to five times more ^{3}H-dThd during the period at 37 °C. After 1 min at 37 °C DNA replication was rapidly terminated by lysing the cells with 1% SDS at 100 °C for 1 min[10]. The lysates from 2–4×10^7 cells were pooled and sonicated briefly to reduce the size of the high molecular weight DNA. The lysate was then treated with Pronase-B (1 mg ml^{-1}, 37 °C, 2.5 h in the presence of 0.4 μg ml^{-1} polyvinyl sulphate), extracted twice with phenol–chloroform (1:1) and precipitated with isopropanol. Over 90% of the RNA was removed by chromatography on nitrocellulose[10]. Uniformly ^{32}P-labelled DNA was prepared by growing 3T6 cells for 2 d in phosphate-free medium containing 10 μCi ml^{-1} ^{32}P-orthophosphate. It was purified as described above using sonication to reduce its size. Nascent ^{3}H-DNA and total ^{32}P-DNA were fractionated together after brief denaturation on 5–20% sucrose gradients in 1 M NaCl, 1 mM EDTA and 50 mM Tris-Cl, *p*H 8, in a SW56 rotor at 50,000 r.p.m. for 3.5 h at 20 °C. Fractions were collected from the bottom, assayed for radioactivity and pooled as indicated. The arrow denotes the position of single-stranded linear ΦX174 DNA (24S). ○, ^{3}H-pulse-labelled DNA; ●, ^{32}P-total DNA.

Table 2 Per cent digestion by spleen exonuclease of pulse-labelled DNA after alkali, ribonuclease or phosphatase treatment

DNA	Size class	Treatment before spleen exonuclease			
		None	Alkali	Ribonuclease	Phosphatase
^{3}H-DNA (nascent)	*a*	35	37	39	59
	b	28±3	36±3	38±3	61
	c	28±4	46±2	46±2	71±9
^{32}P-DNA (sonicated uniformly labelled)	*a*	24	23	21	60
	b	15±2	19±4	20±3	59
	c	10±3	12±5	16±3	69±9

Cultures of 3T6 cells were pulse-labelled with ^{3}H-dThd as described for Fig. 2. After treatment with Pronase for 1 h the lysate was heated at 100 °C for 4 min, chilled and centrifuged for 45 min at 45,000 r.p.m. in a Ti60 rotor at 4 °C to separate high and low molecular weight DNA. The supernatant contains 0.1% of the total DNA and 75–80% of the incorporated radioactivity[10]. DNA in the supernatant was then purified as described for Fig. 2 without sonication, mixed with sonicated ^{32}P-DNA and fractionated into the three size classes on neutral sucrose gradients. Further analyses were carried out as described for Table 1. Ribonuclease treatment used ribonuclease A (Worthington), 20 μg ml^{-1}, plus ribonuclease T1 (Worthington), 20 units ml^{-1} (heated at 80 °C for 10 min to inactivate DNases), for 30 min at 37 °C. Each determination of acid-soluble and acid-insoluble radioactivity involved $5\text{–}50\times10^2$ c.p.m. each of ^{32}P and ^{3}H. The values given for the *b* and *c* size classes are the average of four experiments on four separate preparations of ^{3}H and ^{32}P DNA; the s.e.m. is indicated. When no standard error is shown only one experiment was carried out. Degradation of control 5′-phosphorylated DNA may result from contaminating endonucleolytic activity[19,20]; our observations that 10–15% of circular ΦX DNA is degraded support this possibility. The enzyme concentration, size and type of DNA, conditions of digestion, and techniques used to measure hydrolysis affect the results. In some of our experiments, especially this Table, 5′-phosphorylated DNA was degraded more than the usual 10–15%. We think this is because the ^{32}P-labelled DNA was a few weeks old and that radiolysis had enhanced its sensitivity to alkali or enzymes. The data in Table 1 were obtained with freshly prepared ^{32}P-DNA. The ^{3}H-DNA was always used as soon as practicable after its preparation and we have no reason to think that radiolysis was contributing significantly to its sensitivity to spleen exonuclease. We have found that fragmentation of the DNA by either sonication or partial digestion with DNase I yielded preparations which showed similar low (or high, after phosphatase treatment) sensitivities to spleen exonuclease.

possessing oligoribonucleotide primers which place the value at 33–50% (refs 8, 21).

We routinely observed that nascent DNA not treated with alkali or RNase was more sensitive to spleen exonuclease digestion than was non-nascent DNA, particularly among the smallest molecules after correction for the degradation of the control ^{32}P-DNA. This might be due to the presence of structures in some nascent molecules that are sensitive to an endonuclease activity in the exonuclease preparation (for example, apyrimidinic sites of uracil excision).

The existence of RNA priming of DNA synthesis has been regarded with caution because of the difficulty in demonstrating this mechanism *in vivo*[22]. This is especially true of mammalian DNA, where such data have been lacking. The above experiments show that it is possible to detect this mechanism *in vivo* in intact mammalian cells by using different methods from those used in the analysis of the products of synthesis *in vitro*.

While this work was undergoing review Tseng *et al.*[23] reported results showing good evidence for the presence of short oligoribonucleotides on the 5′-ends of nascent DNA molecules synthesised *in vivo* in human lymphoblasts.

We thank Monica Langlois for technical assistance, Neil Miyamoto for the preparation of spleen exonuclease and alkaline phosphatase, Carol Miyamoto for the preparation of polynucleotide kinase, and Margaret Matthes for many useful discussions. This research was supported by the MRC of Canada and the NCI of Canada.

Biological degradation of TCDD in rats

H. Poiger & Ch. Schlatter

Institute of Toxicology, Federal Institute of Technology and University of Zurich, Zurich, Switzerland

Apart from its high toxicity[1,2], the chemical stability and persistence of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD) in the environment bring about additional hazards[3,4]. However, until now there has been no evidence for degradation of this dioxin in biological systems, and it is considered unusual that a compound which is insusceptible to biological attack should be so extremely toxic. In *in vitro* studies[5] with microsomal preparations from mouse, rat and rabbit liver, as well as *in vivo*, no metabolite of TCDD has been detected by several workers[6–8]. Recent data, showing a lower toxicity of TCDD in rats after stimulation of the hepatic mixed-function oxidase, suggested possible metabolic transformation of this compound[9]. In the present study, we used tritiated TCDD to search for metabolites in the bile of rats and found marked changes in lipophilicity and mobility in TLC of the excreted radioactivity. Treatment with diazomethane yielded at least two new compounds. These observations hinted at the formation of phenolic hydroxyl groups in the dioxin molecule.

Commercially available tritium-labelled TCDD with a specific activity of 41 Ci mmol^{-1} was purified by preparative gaschromatography using consecutively two stationary phases with different polarity (OV 101, DC 560); a radiochemical purity higher than 98.7% was thus obtained. The test animals were female rats from the Sprague–Dawley-derived ZUR:SIV-Z strain, weighing about 260 g. The bile duct was cannulated in both directions with polyethylene catheters which then led to the neck of the animal. After a recovery period of a few days the rats received oral doses of about 20 μCi TCDD dissolved in corn oil and were placed in suitable restriction cages allowing free access to water and feed. Bile was collected in a fraction collector for 3–4 days and then the animals were killed.

The concentration of radioactivity in the bile remained relatively constant throughout the whole experimental period, about 1% of the dose being excreted daily. In the liver tissue, 8.5–12% of the administered radioactivity was found. This radioactivity could be extracted almost completely using dichloromethane as solvent, with about 2% remaining in the residue. In contrast, only 1.5% of the radioactivity from the bile was extractable. This radioactivity was dialysable, so that binding to proteins or other macromolecules could be excluded. However, after incubation of the bile (or the dialysate) with glucuronidase/arylsulphatase (Boehringer), 75% of the radioactivity moved into the organic phase. Only a small part could be removed by lyophilisation (5% from bile, 0.2% from liver). This fraction most probably represents tritiated water because the specific activity remained constant in several successive fractions of the distillate and was not extractable with hexane.

0028–0836/79/430706—02$01.00

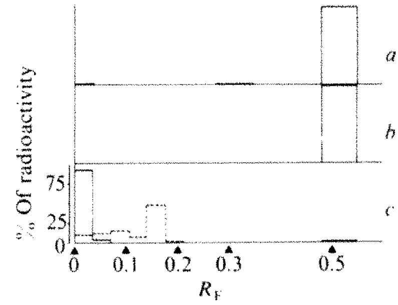

Fig. 1 Radio-TLC of: *a*, tritiated TCDD (as received, not purified); *b*, liver extract; *c*, bile extract (after enzymatic treatment). Precoated silica-gel 60 sheets (Merck), with dichloromethane as developing solvent, were used. The dotted lines show distribution of radioactivity after methylation with diazomethane. Levels of radioactivity were determined in scrapings of 0.5–1 cm zones and are expressed as per cent of the total amount of radioactivity on the silica-gel sheet.

In TLC, radioactivity extracted from the liver was localised at an R_F value of 0.52, where TCDD was also found (Fig. 1). The compound extracted from bile after the enzymatic treatment behaved quite differently. Most of the activity was concentrated at the starting zone, demonstrating a more polar character, with only a small fraction, 1.5%, located at R_F 0.55. Gaschromatographic examination of this extract on a SE 30 column revealed a retention time of the radioactivity similar to that of TCDD; TLC mobility of the material trapped during the GLC examination remained unchanged. When labelled TCDD was added to bile and the mixture left to stand for a few hours, this added fraction could always be extracted with dichloromethane and was found at the position of TCDD on thin layer chromatograms. Thus, chelation of TCDD by any constituents of the bile was excluded. Treatment of bile extracts with diazomethane led to the formation of at least two new compounds with lower polarity than TCDD, exhibiting R_F values of about 0.09 and 0.16.

As only small amounts of the compound were available—concentration in the bile fluid was 50–100 pg ml^{-1}—attempts at mass spectrum analysis were unsuccessful.

Thus, the present results indicate that TCDD is excreted into bile in a metabolised form, as a water-soluble conjugate. These conjugates can be cleaved by enzymatic treatment yielding relatively polar compounds with low mobility on thin layer chromatograms. Esterification with diazomethane diminishes polarity and consequently mobility of the derivative on TLC is increased. Most probably, conjugation occurs with phenolic hydroxyl groups, but their position and number are unknown. Preliminary experiments with double-labelled $^{14}C/^{3}H$-TCDD showed no change of the ratio of the two isotopes after metabolism. This observation makes a hydroxylation at the *ortho* positions unlikely. However, cleavage of the ether group also seems feasible. A decision between these possibilities cannot yet be made.

^{3}H-TCDD was obtained from A. Kende, Rochester, New York.

Note added in proof: Similar results have recently been reported[10].

matters arising

Interstellar grains: organic or refractory?

IT has become fashionable to discuss the possibility that interstellar grains may contain significant quantities of organic material (see ref. 1 and refs therein). I draw attention here to new data which preclude the presence of most organic solids as a significant component of the grains in two typical dark clouds. As pointed out by Duley and Williams[2], virtually all organic compounds containing C and H possess an infrared absorption feature due to C—H stretching at 3.3–3.4 μm. The spectra of several dust-embedded stars in the Ophiuchus and Corona Austrina dark clouds were recently observed with the Anglo-Australian Telescope (Whittet and Blades[3]), in a programme primarily aimed at studying the 3.1 μm ice band. None of these sources, whose visual absorption falls in the range 5–20 mag. shows a feature at 3.3–3.4 μm: the detection limit is an order of magnitude less than the optical depth predicted by Fig. 1 of ref. 2. Similarly (as noted in ref. 2) the spectra of molecular cloud sourcesswith deep ice bands observed by Merrill *et al.*[3] show no C—H feature. It must therefore be concluded that organic grains cannot constitute a significant part of interstellar grain material, even in dense clouds where from other considerations, grain growth is known to occur[5,6].

It seems that the only model for interstellar grains which can simultaneously satisfy their well established dielectric properties[3,7], cosmic abundance constraints[8], and the infrared spectra of highly reddened stars[3,4,9], is one involving a mixture of refractory particles involving compounds of oxygen—silicates and metal oxides—with a possible addition of water ice in the densest regions. Most of the carbon in interstellar clouds is likely to be tied up in gas-phase CO. Candidate grain materials, such as SiO_2, FeO and MgO, are, indeed, abundant in the carbonaceous chomdrites[10].

SAGAN AND KHARE REPLY—We have proposed[1] that a complex organic material, called tholins, produced by electrical discharge or ultraviolet (UV) light from mixtures of cosmically abundant gases, is an important candidate material for the interstellar grains (although other material such as ices and silicates must, of course, be present); and that the sputtering and spallation products of tholins can explain the gas phase organic molecules discovered in the interstellar medium by microwave line spectroscopy. As noted in Fig. 3 of our paper[1] and elsewhere[2], little or no IR absorption is evident in the interstellar medium in the 3.3–3.4 μm region, characteristic of the C—H vibrational transitions of many organic molecules. The observational upper limits correspond, for example, to 10% of carbon in interstellar grains in alkenes and aromatics and 1% in alkanes (ref. 2), and an order of magnitude less according to Whittet. However, as clearly indicated in Table 1 of our paper[1], the atomic abundance of hydrogen by number in tholins is only a few per cent; and, as is apparent from Fig. 2 of our paper, in most laboratory tholins there is no trace of absorption features in the 3.3–3.5 μm range. We have re-examined various IR spectra of tholins and find no clear C—H stretch peak for raw UV tholins; for UV tholins with elemental sulphur removed; for UV tholins with elemental sulphur removed and the sample heated to 450 °C; for spark tholins; and for spark tholins heated to 650 °C. Tholins have a significantly different structure from graphite. We also re-emphasise that a range of other IR absorption features, reliably identified in the interstellar medium, cannot be understood by refractory materials and ices alone; but have a natural explanation if tholins are a constituent of the interstellar grains. The missing ingredient in the interstellar medium seems to be a complex organic solid which has a very weak C—H absorption feature; tholins seem to satisfy these requirements.

The maximum entropy method

THE exposition of the maximum entropy method (MEM) given by Gull and Daniell[1] has been strongly criticised[2] on the basis that it led to some definite solution in situations in which different types of solution are possible (for example, one-peak (one source in astronomical language) and two-peak (double source) solutions). Here we defend Gull and Daniell's theory.

No matter how precise the measurements are, for sufficiently small δ, a point source gives the same observational information as do two nearby point sources at distance δ. Therefore among all brightness distributions, I, that are in accordance with observations, there are values of I corresponding to many-component sources (with as many components as one wishes) with very complicated structure. Astrophysicists want the distribution that contains, crudely speaking, the minimum possible number of components, or, more precisely, the simplest possible distribution in some formal sense. We show here that MEM solves this problem satisfactorily.

How can we formalise this demand? Assuming that complexity is a functional $\int s(I)$. We suppose that it can be represented in the form

$$s_0 + \int s_1(\bar{\sigma}, I\bar{\sigma}))\,\mathrm{d}\bar{\sigma} + \int s_2(\bar{\sigma}_1, \bar{\sigma}_2, I(\bar{\sigma}_2), I(\bar{\sigma}_2))\,\mathrm{d}\bar{\sigma}_1\,\mathrm{d}\bar{\sigma}_2 + \cdots$$

(any analytic functional can be represented in such form). Axiomes for S are as follows. (1) Many-component source. Assume

$$I = I_1 + I_2,\ \mathrm{supp}\ I_1 n\ \mathrm{supp}\ I_2 = \phi,\ \mathrm{supp}\ I_1 = \mathrm{supp}\ I_{1'}$$

We demand that

$$S(I_1) < S(I_{1'}) \rightleftarrows S(I_1 + I_2) < S(I_{1'} + I_2)$$

(if one component is fixed, the image is simpler if the second is simpler). (2) Translational invariance. For any translation T: $S(I_1) < S(I_2) \rightleftarrows S(TI_1) < S(TI_2)$. (3) Independence on choice of unit for flux I: if $S(I_1) > S(I_2)$ and I_1, I_2 are consistent with the same observations (that is

$$\int I_j(\bar{\sigma}) \int A_i(\bar{\sigma}) = C_i \text{ for } j = 1, 2$$

and some fixed $C_i, A_i, A_0 = 1$), then $S(\lambda I_1) > S(\lambda I_2)$.

In looking for the simplest values of I an additive constant in S is inessential. Assuming $S_1 = S_2$ if $S_1 - S_2 = \text{const.}$, then one can prove the following. If S satisfies

0028–0836/79/430708—02$01.00

points (1)–(3), then either

$$S(I) \sim K \int I \ln I \, \mathrm{d}\bar{\sigma},$$

or

$$S(I) \sim K \int I^{\alpha} \, \mathrm{d}\bar{\sigma}$$

for some constants K, α ((1) leads to $S_2 = S_3 = 0$, (2) leads to

$$S(I) \sim \int \tilde{\bar{S}}_1(I(\bar{\sigma})) \, \mathrm{d}\bar{\sigma}$$

for some $\tilde{\bar{S}}_1$).

MEM is usually chosen, because in all other cases $I \geqslant 0$ is an extra complication and here it follows automatically from the variational principle.

V. JA. KREINOVIC
O. M. KOSHELEVA

Astrophysical Observatory

1. Gull, S. F. & Daniell, G. J. *Nature* **272**, 686 (1978).
2. Fiddy, M. A. & Greenaway, A. H. *Nature* **276**, 421 (1978).

FIDDY AND GREENAWAY REPLY—We thank Kreĭnovič and Kosheleva for their remarks concerning our criticism[1] of phaseless object reconstruction using the maximum entropy algorithm[2] and other statistical techniques. The paper giving a more detailed explanation of our criticism is not widely available[3]. Because of this, we are taking the opportunity to supplement our necessarily brief discussion[1], and to comment on the points which they have raised.

Their statement in the paragraph beginning "No matter how precise . . ." is an oversimplification. The claim may be true if the multiple sources in question are distributed over a region unresolved by the measurement baseline. However, if the measurements are precise, one may analytically continue the data and thus amend the resolution criteria. Also, the use of entire function theory enables one to predict a countable, complete and often finite set of possible solutions, from precise measurements. In ref. 3 we give examples of the possible solutions consistent with an intensity distribution. In only one case do all the solutions correspond to a double source. The essential point, which is apparent from the other examples, is that even within the given resolution criteria for the truncated data, there is the danger of confusing single and multiple sources when making phaseless reconstructions.

To say that one only requires "the distribution that contains . . . the minimum possible number of components", implies lack of interest in multiple systems. If only upper limits on source extent are required, one may use the measured object autocorrelation. If the source structure is of interest, it is important to ask what the ambiguities are, and to classify them as possible single, double, triple systems. Entire function theory predicts that such a classification is possible, the range of solutions being countable.

We do not deny the usefulness of the maximum entropy method, since with phase information it provides an extremely powerful tool. Gull and Daniell[4] note the possible existence of several entropy maxima and comment that in such cases the reconstruction "will be misleading". They continue "with phase information . . . this cannot happen". We concur, believing that such multiple entropy maxima correspond to ambiguities of the type discussed in refs 1 and 3.

Effects of sodium butyrate on human chronic myelogenous leukaemia cell line K562

ANDERSSON and his colleagues have postulated that the K562 cell line is of erythroleukaemic origin[1] and can be induced to undergo erythrocytic differentiation by sodium butyrate[2]. However, treatment with sodium butyrate of the original K562 cells fails to produce benzidine-positive staining, cell haemoglobin crystals or the synthesis of human globin.

The K562 cells (initial density 2×10^5 cells ml^{-1}) were cultivated in medium described elsewhere[3–6] in the presence or absence of 1 mM sodium butyrate. In contrast to Andersson's observation, sodium butyrate inhibited the cell growth by 50%. Thus, after 3 d, control cultures contained 8.7×10^5 cells while butyrate-treated cultures had 4.3×10^5 cells. No differentiation was detectable. The Lepehne reaction did not reveal a single benzidine-positive cell. We did, however, observe that cells from cultures treated with butyrate showed various signs of degeneration such as vacuolation, hyaline degeneration and loss of the cytoplasmic basophilia. Electron microscopy also showed various signs of cell injury.

In the normal sequence of erythroid differentiation the cell progresses through a series of definitive recognisable stages culminating in a mature erythrocyte. Andersson *et al.*[2] showed the intracytoplasmic generation of erythrocyte-like bodies which were subsequently expelled from the original cell. This phenomenon has not been described before and these 'erythrocyte-like' particles are probably only hyaline bodies and/or pieces of cytoplasmic debris. Furthermore, neither treated nor control cells synthesised α- or β-globin chains (Fig. 1) as would be expected if erythroid differentiation has occurred. With the report of Rutherford *et al.*[7] in mind, note that embryonic globin polypeptides are not detectable by the column chromatographic procedure used. Thus, it is not possible to exclude the possibility of synthesis of trace amounts of embryonic globin polypeptides, but it seems convincing that adult globin was not synthesised in cells treated with butyrate.

Because our K562 cells do not stain positively after exposure to sodium butyrate we also studied the effect of sodium butyrate in myelosarcomas made up of K562 cells transplanted in nude mice[8,9]. Six intraperitoneal injections of sodium butyrate (275 mg per kg every 2 d) produced extensive necrosis of the myelosarcoma. Imprints from K562 tumours growing *in vivo* in nude mice also failed to show benzidine-positive cells. However, when we attempted to reculture the cells from tumours, ~10–15% of the cells did give positive benzidine staining. These cells were not typical erythroid cells and showed well defined nucleoli. It is most likely that they were of mouse origin or the K562 cells were somehow altered by passage in the mouse to give a false positive benzidine reaction. If Andersson's cells have at any time been passaged in immunodeficient mice, this may account for the benzidine-positive cells. We do not know which clone or subline of K562 was used by Andersson *et al.*[1]. In March 1978, we sent to Dr Eva Klein a clone of K562 which was recultured *in vitro* after being serially transplanted in nude mice for 20 passages. Klein also had a subline of K562, originally provided to Dr G. Henle six years ago, and the myeloid origin of this subline was confirmed by Klein *et al.*[10]. Evidence for the myeloid nature of K562 cells is further supported by the presence of group-specific granulocyte antigens[11].

Another claim of erythroid origin rests primarily on the biosynthesis of glycophorin A, the major sialoglycoprotein of human erythrocytes, by K562 cells[12]. Unpublished results show a very low number of glycophorin A cells in our K562 cell line and no conclusions can be made yet.

In summary, the failure of sodium butyrate to induce erythroid differentation of K562 cells is consistent with our earlier studies on the effects of dimethyl sulphoxide[13]. Both agents produce cytotoxic effects rather than a stimulation of the cell potential for differentiation. The discrepancies between our findings lead us

0028–0836/79/430709—02$01.00

to question whether Andersson's cells are indeed K562 cells. The K562 cell line was originally established in our laboratory from a pleural effusion of a patient with chronic myelogenous leukaemia in terminal blastic crisis[3-5] and has been found to be a highly undifferentiated cell of the granulocytic series[5,6,10,11] with a consistent ultrastructural pattern[14]. It is the progenitor of all K562 sublines now in existence. The possibility of spontaneous changes through clonal evolution or of contamination with other cell lines and subsequent overgrowth or hybridisation cannot be discounted after the cells have been grown outside our laboratory for so many years. Characteristics lacking in the parent cell line may be present in a subline which acquired them at some stage after leaving our laboratory. In any event, the classification of the K562 cell line as an erythrocytic precursor is certainly premature for the evidence available. The presence or absence of glycophorin A in highly undifferentiated precursors such as the stem and differentiating cells has not yet been established and so it should not be considered solely as a marker of the erythrocytic series. Morphologically, the K562 blasts are probably closer to haemocytoblasts than pronormoblasts or proerythroblasts depending on the terminology used.

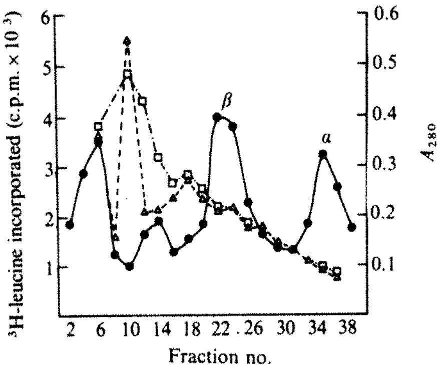

Fig. 1 Elution profile of globin chains on CM-cellulose-urea columns. Absorbance of globin chains from carrier human haemoglobin (●) is shown in comparison to the incorporation of ^{3}H-leucine into polypeptides obtained from control cells (□) and from K562 cells incubated in the presence of 1 mM sodium butyrate (△). After addition of label at 48 h cells were pelleted at 12 h of incubation and then washed in excess saline[15]. H_2O (1 ml) and carrier human haemoglobin was added. Globin was prepared by precipitation in acid acetone (1.2% HCl in acetone)[16]. The lyophilised globin was resolved into constituent polypeptides by chromatography on CM-cellulose columns in 8 M urea[17]. A phosphate gradient from 0.005 M to 0.03 M was used and 2.5-ml fractions collected. Aliquots (0.5 ml) were then used for scintillation counting.

This investigation was supported by grant numbers CA-18185-04 and CA-17553-04 awarded by the NCI, DHEW.

ANDERSSON *ET AL.* REPLY—Lozzio *et al.* challenge our conclusion that the K562 cell line has the capacity for erythroid differentiation and raise doubts that we have studied the authentic K562 line.

The cell line was originally obtained from Lozzio via W. Henle. A detailed account of its characteristics was given by Klein *et al.*[1]. The karyotype of our K562 cells is obviously identical to that originally described by Lozzio and Lozzio[2]. Contamination with mouse cells or with mouse/human hybrids can be excluded, as the cells have never been carried *in vivo.*

Concerning the erythroid versus granulocytic nature of the K562 cells, we have demonstrated that: (1) The surface glycoprotein pattern of K562 cells resembles that of normal erythrocytes[3] but is completely different from those of other haematopoietic cell lines[4,5] of the promyelocytic leukaemia line HL-60[6] and of granulocytes[7] and their benign and malignant precursors[8]. (2) Our K562 cells carry on their surface 1.1×10^6 glycophorin A molecules per cell[9] which are synthesised by the cells[10]. (Glycophorin A is the major sialoglycoprotein of human red cell membrane and is present only on erythroid cells in human bone marrow[11].) (3) K562 cells synthesise haemoglobin in the presence of sodium butyrate[12] as shown by the Lephene's benzidine and by radioimmunoassay indicating the presence of both the haem and the globin parts. Rutherford *et al.* recently reported that K562 cells synthesise embryonic and fetal haemoglobin in the presence of haemin[13]. The identities of the haemoglobins have recently been confirmed by peptide mapping (T. R. Rutherford, personal communication).

The different observations on phenotype of the K562 cells by us[12] and Rutherford *et al.*[13], as compared to those by Lozzio and Lozzio[2], are not easily explained. As the original K562 cell line was not initially cloned the possibility exists that we have been investigating selected subpopulations of the cell line endowed with different differentiation capacities. (This is also frequently seen in the Friend leukaemia system.) Therefore we suggest an interchange of our respective K562 cells for comparative studies.

Regardless of the real phenotype of the K562 cells, the establishment of this unique cell line by Lozzio *et al.* is highly creditable. This has provided an excellent model for human haematopoietic differentiation.

Note added in proof: Recently we obtained K562 cells (passage 239) directly from Lozzios' laboratory (courtesy of Dr R. A. Laine). These K562 cells have a strong surface expression of glycophorin A as shown by immunofluorescence and immunoprecipitation from surface labelled cells with specific antiglycophorin A antiserum.

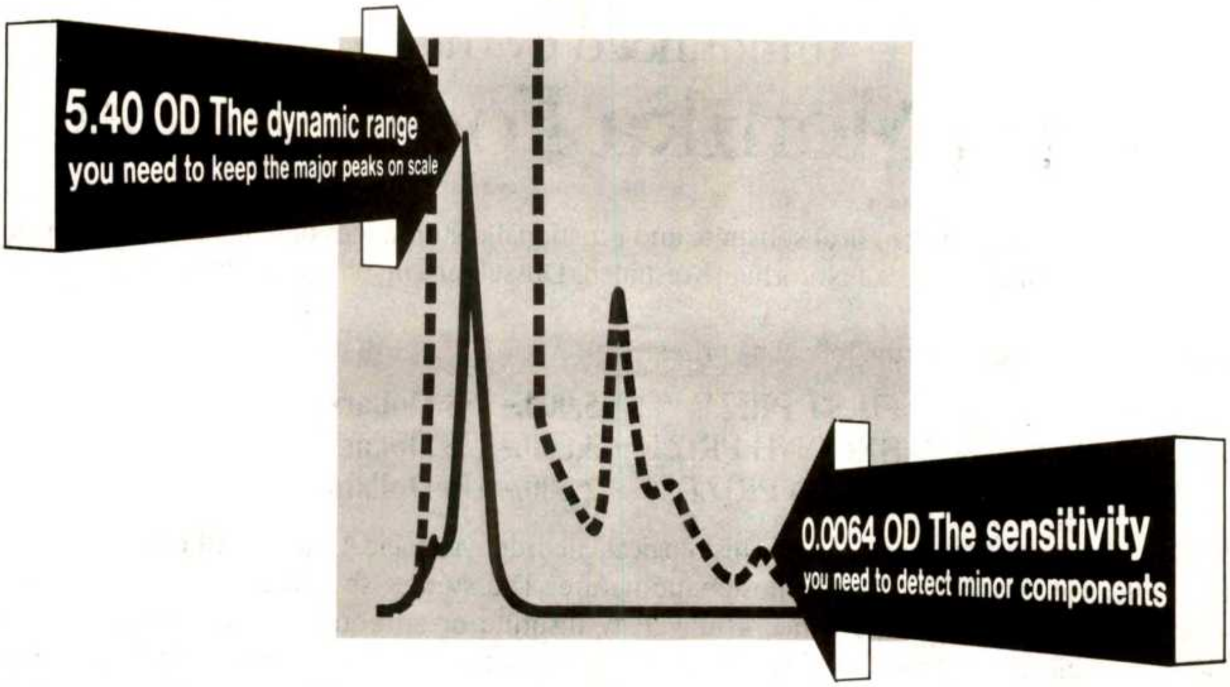
Now you can have it both ways!



5.40 OD The dynamic range
you need to keep the major peaks on scale
0.0064 OD The sensitivity
you need to detect minor components

Pharmacia Dual Path Monitor UV-2

has a unique flow cell with two optical path-lengths for new versatility in UV-monitoring.

- Monitor absorbance quantitatively up to 20 OD units full scale with a sensitivity of 0.005 OD units full scale at the same time, in the same run.
- Monitor at 254 nm and/or 280 nm with two completely independent measuring systems.

The Dual Path Monitor UV-2 has all the other features you expect of a high performance monitor: stability, cold room operation convenience and compact design. For less-demanding applications you can choose the Pharmacia Single Path Monitor UV-1 with a choice of 3 mm or 10 mm flow cell and operation at 254 nm or 280 nm.

Find out more about the practical advantages of column monitoring with the UV-2 and UV-1 Monitors. Ask about the Pharmacia Recorders too.

Prize competition

announced by the

Anna Monika Foundation

for the investigation of the physical substrate and functional disturbances of depressions by approval of the Minister of the Interior of Nordrhein-Westfalen, Düsseldorf, on 9th June, 1965.

The Foundation announces the following prizes:

FIRST PRIZE	**15,000.- US Dollars**
SECOND PRIZE	**5,000.- US Dollars**
THIRD PRIZE	**2,500.- US Dollars**

preferably for studies of biochemical, histological, neurophysiological, neuropathological, psychopharmacological, psychiatric or psychosomatic nature. The studies should be carried out in close co-operation with a psychiatric clinic, a university institute or an equivalent scientific institution. So far as possible, the papers should give information about recent advances in knowledge that would be helpful in promoting treatment and would open up new paths of progress. The papers may be written in German, French or English and should be submitted to the Chairman of the Committee, Professor Dr. P. Kielholz, Basle, Switzerland. Besides hitherto unpublished studies, papers published in the past two years in a German or international professional journal may also be submitted. *Deadline for submission to the Committee is 30th September, 1980.* To help the Committee to come to a speedy decision it is requested that at least four copies *including an abstract covering the content of all papers must be submitted.* Prizes will be awarded on the 30th June, 1981. If, in the opinion of the Committee, no papers of sufficient merit are submitted, it reserves the right to make no award. Prizes and their amount will be awarded according to the merits of the study in question. Subject to the Committee's decision, each prize can be devided between two papers.

The Committee of Judges Includes:

Chairman: Professor P. Kielholz, M. D.
Director of the Psychiatric Clinic of the University of Basle, Wilhelm-Klein-Straße 27, CH-4056 Basle/Switzerland

Members: Professor Hugo Aebi, M. D., Head of the Department Medizinisch-Chemisches Institut, University of Berne/Switzerland

Professor Dr. Otto Creutzfeldt, Director of Max Planck Institute of Biophysical Chemistry, Göttingen/Germany

Professor H. J. Dengler, M. D., Director of the Medical Clinic of the University Bonn/Germany

Professor Fritz A. Freyhan, M. D., F.A.P.A., Washington/USA

Professor K. Heinrich, M. D., Director of the Psychiatric Clinic of the University of Düsseldorf/Germany

Professor H. Hippius, M. D., Director of the Psychiatry Hospital of the University of Munich/Germany

Professor Dr. Horst Jatzkewitz, Max Planck Institute for Psychiatry, Munich/Germany

Professor Dr. D. Palm, Director of the Pharmacological Institute of the University of Frankfurt-Main/Germany

Professor Pierre Pichot, Heat of Medical Psychology, Centre Psychiatrique Sainte-Anne, Paris/France

Professor Dr. Dr. Wilhelm Stoffel, Director of the Institute of Physiological Chemistry of the University of Cologne/Germany

Managing Director: Professor Dr. Benno Hess, Anna Monika Foundation, D-4600 Dortmund 1, Töllnerstraße 9-11.

Management of controversy

Eric Ashby

Controversy: Politics of Technical Decisions. Edited by Dorothy Nelkin. Pp. 256. (Sage Publications: Beverly Hills and London, 1979.) Hardback $16, £10; paperback $7.95, £5.

SCIENCE-AND-SOCIETY, hyphenated like this, is now a well established subject for study, with departments, professors, journals, conferences, research grants: all the apparatus of an academic discipline except a codified content. This is not a pejorative assertion. A codified content takes time to evolve; premature generalisations might become obstacles to evolution; the most helpful contributions to make at this stage are in the 'natural history' of the subject: descriptions of what actually happens (the echo of Ranke's recipe for writing history "*wie es eigentlich gewesen*") and cautious comparisons of what seem to be similar episodes.

This is what Dorothy Nelkin has been doing for some time. She has published case-studies of controversies about the siting of a nuclear power station, about the extension of the Boston airport, about housing politics, about military research at MIT; all controversies: for the first lesson the novice has to learn in this subject is that sweetness-and-light is not only impracticable, it is undesirable. Controversy is essential to the resolution of the problems that arise from the applications of technology to social ends. It's a consequence of political freedom. So attention has to be given, not to the elimination of controversy but to its management. Who has the right to take part? How can those who take part have access to information? What is the appropriate forum for the controversy: a court of law, a ministerial public enquiry, a panel of experts, a clash of pressure groups? Experiments which might provide answers to these questions are going on all the time. The Royal Commission on Electric Power Planning in Ontario has published some notable material; so has the Electric Power Research Institute in California; so, in Britain, has the Advisory Committee on Trunk Road Assessment. But the most useful material for the student is a collection of documented case-studies, as little coloured by prejudice as is possible in a subject where exaggeration, sensationalism, and distortion of the facts are the very raw material in the process.

This is what Dorothy Nelkin has achieved in her editorship of this useful collection of twelve case-studies in the politics of technical decisions. The studies are intended to "provide students with a sense of the kind of reasoning that motivates public agencies, government officials, scientists, and protest groups". She distinguishes four kinds of controversy and the contributors to the volume give three examples of each kind. They are: efficiency versus equity, as in the siting of an airport; benefits versus risks, as in the controversy over nuclear wastes; regulation versus freedom of choice, as in the prescription of certain drugs not because they are dangerous but because they appear to be useless; and science (the rational approach to nature) versus traditional values (opposition to the pursuit of knowledge irrespective of where it might lead.) Each case-study is well supported by references to primary sources.

I would like someone to write a monograph on controversies about airports. Heathrow is a shameful example of the incompetence of the British in the planning of air transport and the futility of the present state-of-the-art of technology assessment. But we have no monopoly of incompetence. In the 1950s there was a vast investment in Gander airport in Newfoundland, "just before the introduction of jet aircraft made nonstop trans-Atlantic flights possible". Then, as a case-study of the Toronto airport goes on to explain, came the proposal to site a second airport in Toronto. One motive was rivalry with Montreal; if Toronto didn't expand, Montreal would become the "gateway to Canada". Another motive was to pacify people living near the present airport. Opposition to a new airport developed rapidly, just as it is now doing in Britain to oppose any site for a third London airport. It coalesced under a good emotive label: POP — People or Planes. Among the supporters of the opposition was one aircraft manufacturer, who saw a better market for short take-off craft if there were to be only one airport in Toronto. One interesting and significant point which the essay makes is that the real issues were political but they were often camouflaged as scientific or technical.

The most interesting essay in the book, because it draws upon almost inaccessible sources, is one on environmental conflict in the USSR. With a wealth of references, almost all Russian, Thane Gustafson describes the awakening of an environmental conscience in the Soviet Union. He effectively dispels any notion that it came from the grassroots. But he shows that the genuine concern about the condition of Lake Baikal was not solely for commercial expediency: "Through literature and folklore, every Russian from childhood knows its beauty". And this was a powerful factor in the campaign to clean the lake. Concern for water management and opposition to the siting of dams arose because it was causing a serious alienation of valuable agricultural land. But the new environmental programme owes its impetus to the influence of scientists, aware of the concern for conservation in Europe and America, who have made themselves audible in the councils of the Kremlin.

All the case-studies are interesting and a few comments on them will illustrate how well they have been chosen. The familiar ban on the use of diethylstilbestrol (DES) is an example of the need to balance the benefits of more meat against the potential disbenefits of cancer: one a certainty, the other an unproven possibility. It is noteworthy that the Food and Drug Administration avoided justifying the ban on grounds of the notorious Delaney Clause because President Nixon proposed to Congress that this clause should be "diluted" to avoid some of the more crazy consequences of its application "to ban all foods because they contain a few molecules of naturally occurring carcinogens".

There is a historical chapter, showing that controversies about the uses of science are nothing new, which traces the opposition to smallpox immunisation in the eighteenth and nineteenth centuries. And there is an ominous account of an attempt — yes, as late as the 1970s — to give equal treatment to the theories of evolution and of special creation in the teaching of biology in California. California buys about 10% of the nation's textbooks and it was seriously proposed that special creationists should have at least equal consideration in textbooks with the consideration given to orthodox biology. The National Academy and the American Association for the Advancement of Science had to throw their weight into the controversy. Perhaps we should not be surprised; astrologists can still make a good living in Britain and it is often said that more people make a living out of astrology than out of astronomy.

This book is a useful addition to a small, but growing, literature of case-studies of this kind. By far the best, though its scope is limited to planning enquiries, is Roy Gregory's *The Price of Amenity* (Macmillan, 1971). There is also, for British examples, the book edited by Peter Smith, *The Politics of Physical Resources* (Penguin, 1975), though some of the essays in this book are far from objective; and a book edited by R. Kimber and J.P. Richardson, *Campaigning for the Environment* (Routledge and Kegan Paul, 1974). The most comprehensive summary, though the case-studies are unfortunately very brief, is in the book edited by Edward Lawless, published by Rutgers University Press in 1977 (reviewed in *Nature*, **274**, 295-296; 1978) under the unpromising title *Technology and Social Shock*.

So there is now the nucleus of a library which will promote the evolution of science-and-society into a respectable discipline. Dorothy Nelkin's latest contribution to this is very welcome. ☐

Lord Ashby is Chancellor of Queen's University, Belfast, and Fellow of Clare College, Cambridge, UK.

Encyclopaedic approach to technology

A History of Technology. Vols VI and VII: *The Twentieth Century, c.1900 to c.1950.* Edited by T.I. Williams. (Clarendon/Oxford University Press: Oxford, UK, 1979.) £25 and £27.

TWENTY-FIVE years ago the now classic first volume of *A History of Technology* appeared from the Clarendon Press. This year, we welcome the sixth and seventh (and last) volumes in the series. With them we arrive, in history, where the series itself began, in the early 1950s. Together, these seven magnificent volumes form a monument of scholarship. Monuments normally inspire criticism or veneration; rarely use. This one is different.

From the early days of his collaboration with Charles Singer, E.J. Holmyard and A.R. Hall, Williams enjoyed the cooperation of a legion of eminent scholars whose unquestioned technical expertise made their contributions definitive. In editorial standards, range and clarity, the present volumes continue their predecessors' tradition of high scholarship. Nonetheless, 25 years is a long time in historiography, as in technology. Moreover, a new generation (and profession) of historians has emerged, with significantly altered perceptions of the social function of technology and technologists. With them, the reader is compelled to ask in these more cautious times, has the history of technology progressed as far as the technology it describes?

In reply, these two volumes invite comment at three levels. First, these chapters are, in technical terms, proverbially encyclopaedic in breadth and detail. Like their predecessors, these volumes describe a spectrum of activity, from fuels to food, metals to textiles, chemicals to buildings and transportation. Some chapters bring the story 'up to date'; others (space, aircraft, medical and ocean technology, and computers) describe recent additions to the "relief of man's estate". Although experts may differ (a possibility frequently raised, if indifferently addressed), one can scarcely debate the pronouncements of Lord Montagu of Beaulieu on motor cars, or of Colin Buchanan on town planning. Several other chapters — including Frank Greenaway's on instruments and Brian Bowers' on electricity — offer fresh insights as well as information. But these technical chapters together seem less than the sum of their parts. There is, despite the editor's catholicity, a deceptive provincialism of outlook which emerges in many of them. A mixture of "practical men" and university men (in about equal parts) is not necessarily an unsatisfactory formula for a fine product; but the fact that the contributors are overwhelmingly British, and, with perhaps ten exceptions, are not professional economic or social historians, points clearly to one difficulty. Another lies in the subject-matter itself.

One cannot criticise the authors for failing to make obligatory reference to microelectronics or biotechnology (although, indeed, there are none). But it will not escape notice that many of the 58 contributions (notably excepting the editor's own) follow historiographical conventions remarkably similar to those of educated amateurs a generation ago. Most technical chapters are history preserved in aspic, sadly neglecting systematic comparative analytical discussion. Excellent descriptive accounts of leading technical developments in different fields may nonetheless strike many a current reader, of say, "Technology and Culture", as dry, stylised and lacking in economic and social insight. On the one hand, few of the technical chapters even attempt to demonstrate the connection between entrepreneurial and management styles in research and development, and the problems of marketing and diffusion in different countries under different economic systems. On the other hand, few contributors pause to ask, how can we use this knowledge to understand the developments of the *next* twenty years?

Second, as the editor explains, technology advances across a broad front, or not at all. Yet the editorial arrangement of technical contributions, inevitably dividing knowledge into arbitrary categories, militates against the authors asking larger questions about the nature of the technologies concerned. Today, whatever may be one's opinion, for example, of 'appropriate technology', the reader will want to know in what ways technological development (whether in fuel, transport, housing, and so on), has been shown capable of responding to altered economic and social realities. It could be argued, in defence, that in the 1950s, most scholars and the English reading public were as uninterested in the relationships of production as they were unaware of the implicit risks of technological development. But whatever one's approach to economic history, no account of technological development which omits to describe the organisation and operation of the modes of production characteristic of industrial capitalism can today be considered complete.

If this criticism is sound, it is even more to be regretted, as the editor is clearly sensitive to the issues involved. Indeed, for this reason, Mr Williams has gone outside the ranks of the technological *cognoscenti*, and has invited several chapters of contextual discussion — including an historical overview from T.K. Derry, and chapters on innovation by David Sawers; on the economics of technology by Frank Bradbury; on management by Glenn Porter; on trades unions by Harold Pollins; on education by David Layton; on government by Alexander King; and on the chemical industry by Lutz Haber. These contributions are of varying quality (Haber's and Layton's in particular deserve a wider readership), but whatever their individual merits, they do not together weave a comprehensive fabric. Written, one supposes, in isolation from each other, they largely fail to reveal the depths of controversy reigning within these areas of discourse. The explanations offered are, in many ways, too consensual, too safe, and altogether too undemanding. When they jar, then, like a clock striking thirteen, they cast doubt on all else. For example, David Sawers concludes provokingly that "the nature of . . . technology appears to influence the nature of the industrial structure more than the structure influences the technology". Surely, the two volumes of evidence which follow could, if skilfully used, demonstrate, disprove, or at least illuminate this assertion. At the very least, the economic and social analysis of new technologies cannot be merely relegated to separate chapters. At a more philosophical level, far more could be said about the relationship between technology and cultural expectations. For example, it could be argued (with important qualifications) that a presumed alliance between liberal values and technological growth was widely considered axiomatic in the 19th century; but Derry's passing reference to this fails to demonstrate why this should have been so, or what relevance

Marine Biology Letters

WRITE NOW FOR A FREE SAMPLE COPY.

Editors-in-Chief: D.J. CRISP, N.E.R.C. Marine Invertebrate Biology Unit, University College of North Wales, Bangor, LL57 2DG, Wales, U.K. and R.K. KOEHN, Department of Ecology and Evolution, Division of Biological Sciences, State University of New York at Stony Brook, N.Y. 11794, U.S.A.

Aims and Scope

The journal will provide a medium for the rapid publication of essentially short, definitive articles on marine organisms, which are broadly concerned with biophysical, biochemical and physiological processes as they affect the individual or the population.
Specific areas to be included are:- sensory and motor neural mechanisms; respiratory physiology and energy metabolism; aspects of nutrition and reproduction; homeostatic mechanisms and hormonal control; experimental embryology and cytology; biochemical and population genetics. Articles on multidisciplinary studies will also be considered and occasional reviews will be published following invitation by the Editors-in-Chief.

The first issue includes the following articles

Excretion of CO_2 in water-breathing animals
James N. Cameron
Levels of polypeptide elongation factor 1 in relation to adaptation of protein synthesis in tropical fishes
Jennifer B.K. Nielsen
On the energy demand of the posterior adductor muscle of *Mytilus edulis* in catch during exposure to air
R.H.M. Ebberink, W. Zurburg and D.I. Zandee
Fumarate reductase of *Mytilus edulis* L.
D.A. Holwerda and A. de Zwaan

Using Iodine-125?

New Microvial*

- reduced exposure
- reduced contamination risk

Reduced exposure

The new packaging consists of 2 parts

- An outer plastic container incorporating a steel shield
- An inner plastic vial with a conical glass insert containing the iodide solution

Reduced contamination risk

The cap of the plastic outer container is keyed so that it can be used to unscrew the cap of the inner vial — no need to handle this vial from start to finish.

Drawings of British Plants
STELLA ROSS-CRAIG

As each part of *Drawings of British Plants* was originally published, it received consistently high critical acclaim, and the whole work became established as a standard reference which was not only accurate but beautiful. It is now reissued for the growing number of people who are concerned with nature conservation and the diversity of plants inhabiting the British Isles. It is the ultimate work of reference for both professional and amateur.

'For the selection of species . . . and for their beautiful and accurate representation, there can be nothing but praise.' *Journal of the Royal Horticultural Society*

THE MACMILLAN DICTIONARY OF ASTRONOMY

Valerie Illingworth

This Macmillan Dictionary reflects the explosive growth of astronomy in the last few years. It contains up-to-date references to the many exciting developments and discoveries that have been made in these years as well as to established theories.
It is a concise and comprehensive work; fully cross-referenced, it contains illustrations and diagrams making it the ideal personal reference book for both the specialist and the interested layman.

this belief in "technologism" had to subsequent political and social development. Here and elsewhere historical judgements will not escape historical criticism. And in the meantime, many important relationships — between technology and empire, between political and "technological dependence", between civilian and military technology, and between the "technostructures" of different economic systems — are simply not adequately treated.

Browsing through these excellently produced volumes, the reader may, at length, ask a third question. Social history, Trevelyan once remarked, is history with politics left out. The history of technology is, traditionally, history with the people left out. Beyond inventors, corporations and eponymous effects, this *History of Technology*, like its predecessors, largely fails to situate technological developments at the level of human beings caught up and affected by them. This separation between the word and the thing has until recently rendered much of the history of technology an arid discipline, often bereft of human reality. It has been by all accounts a *hasard du métier*. But the time has come to catch up, at least, with recent historiography. In these volumes, revealingly, the excellent photographs wordlessly describe much of the reality that the text leaves unstated. Even to the casual reader, pictures of working conditions in the paint industry (Fig. 23.3) rest uneasily next to discussions of chemical development. And one supposes that the plate (Figs.21.15 and 21.16) which offers an ironic (and unintended?) juxtaposition of *men* in lab coats in Levenstein's Manchester works (about 1912) alongside *women* in overalls cleaning chemical casks (about 1943) will not pass unnoticed by students of technology and the labour process. Nor, for that matter, will feminist historians leave unchallenged the chapter on domestic appliances, which manages to describe a host of new inventions, and mentions more than once the "servant class", without once referring to the commonplace contradictions of "liberating technology" in modern society.

Methodologically, it can be argued that the omnibus, encylopaedic approach to technology represented in these volumes, has had its day. What of the future? In the last chapter, written by the editor, there is a beginning. Mr Williams, as a good historian, looks forward, and in his summary he sees the chief lesson of the past and the problem of the future as basically one of choice — one of selection — between different technologies. Other historians, economists and even technologists today would argue that the real problem, no less pressing in the Third World than in the West, is not merely one of choice between different technologies, but of choice between different styles of life. Mr Williams sees clearly the difficulty of first defining an acceptable goal, then creating the technology necessary to achieve it. But to do something like this, after all, is surely part of the technologist's credo. And in failing to set and observe clear social priorities, technology in the West has been allowed to become less a means and more an end in itself.

Historians now widely recognise that it is the fate of technology not to have an ideology, but to be one. As Langdon Winner has recently observed, the fear that technologies and the factors governing them have become 'autonomous' outside the rational control of governments, or engineers, is part of the Western condition. There is no reason, on current calculations, why this fear should not also one day confound large parts of the Third World. Since *Silent Spring*, the environment, and since the oil crisis, energy, have become the two principal epicentres of disquiet with technology. But the historical and philosophical issues raised in *A History of Technology* are not confined to these matters alone. That these last volumes are edited by Trevor Williams alone, no longer aided by a large industrial subsidy, itself speaks volumes for the change in our circumstances.

When they turn back to his *History* for technical answers, readers of these volumes will be left asking important questions. One hopes they will find the editor sympathetic. Is it sufficient, today, for example, to deplore alleged 'constraints' on 'progress', when one is forcibly reminded almost every day of the traumatic story of nuclear power from Los Alamos to Harrisburg? If not in the 1950s, then from the 1970s some conception of 'open' technology will require a place alongside participatory access to 'open government'. In the process it is not only the technologist and the politician, as Mr Williams suggests in an adventitious pun, whose resources will be taxed in the search for solutions. If the future lies in the discovery of alternatives, solutions can lie only in ourselves.

Hot-atom reactions

Chemical Effects of Nuclear Transformation in Inorganic Systems. Edited by G. Harbottle and A. G. Maddock. Pp.540. (North-Holland: Amsterdam, London and New York, 1979.) $87.75; Dfl. 180.

ATOMS undergoing almost any nuclear process are characterised by excitation energies usually far in excess of the energies associated with chemical processes. The excitation may be in the form of kinetic or electronic energy (including ionisation), the amounts depending on the nature of the nuclear process occurring. If the process gives a radioactive atom, the atom is conveniently 'tagged' at birth and its subsequent fate readily followed.

The chemical effects of the nuclear process are firstly to cause rupture of some or all of the bonds in which the atom was involved and secondly to allow the atom to undergo novel types of reaction not normally observable in conventional chemical systems. These are normally called 'hot atom' reactions, as the excitations involved correspond to 'temperature' of the order of 10^5K or higher.

The present volume is a comprehensive survey of these reactions occuring in inorganic systems, up to the mid-1970s. It has 27 chapters contributed by 28 authors and lists some 1900 references in total. The limitation to inorganic systems may seem somewhat arbitrary, but in fact the coverage of the whole field is good and few if any topics of fundamental importance are omitted.

After a short historical introduction the first few chapters deal with the primary processes following nuclear activation and reactions in the gas phase. Gas phase studies have contributed significantly to our understanding of high energy reactions through the work of Wolfgang, Rowland and others. However, as most inorganic compounds are not gaseous , the vast majority of the work covered here deals with the condensed phases, especially solids. Much of the work on solids has been stimulated by the phenomemon of 'annealing' in which the activated atom, having undergone bond rupture during nuclear activation, returns to the form of the parent compound as a result of a variety of treatments, such as heating or gamma irradiation.

The division of the chapters is made on broadly chemical criteria, so that each group of compounds is treated separately. This makes sense because by far the most popular method of nuclear activation is the (n, γ) reaction and there are separate chapters dealing with other nuclear processes such as isomeric transition, beta decay, fission fragments, and so on.

A major experimental problem in studies on solids is the need to dissolve the solid in order to analyse products. The possibility of reactions during or after dissolution makes it difficult to be sure of the precise nature of the species present in the solid. Numerous attempts to overcome this difficulty have been made and some of these are reported here. One obvious approach is direct studies on the solid itself, but this is difficult because of the exceedingly low concentration of radioactive atoms usually present. Mössbauer and related techniques have yielded some information in this area, but by no means solve the problem.

In summary, this volume provides a comprehensive study of the state of the art in this subject. It accurately reflects the uncertainties as well as the progress made. The standard of treatment is somewhat variable, as might be expected with such a large number of contributors, but the editors have done an excellent job in avoiding overlaps and repetition. The price will probably put the book beyond the reach of even the most enthusiastic individual, but it should certainly find its place in libraries. **V. J. Robinson**

Energetic Mancunian

James Prescott Joule and the Concept of Energy. By H.J. Steffens. Pp. 172. (Neale Watson: New York; Dawson: Folkstone, UK, 1979.) $20; £10.

NEARLY a century ago a reviewer in the *Philosophical Magazine* wrote:

> "Not Copernicus and Galielei, when they abolished the Ptolemaic system; not Newton, when he annihilated the Cartesian vortices; not Young and Fresnel, when they exploded the Corpuscular Theory; not Faraday and Maxwell, in their splendid victory over *Actio in distans* — more thoroughly shattered a malignant and dangerous heresy, than did Joule when he overthrew the baleful giant FORCE, and firmly established, by lawful means, the beneficient rule of the rightful monarch, ENERGY! Then, and not till then, were the marvellous achievements of Sadi Carnot rendered fully available; and Science silently underwent a revolution more swift and more tremendous than ever befell a nation".

None of this Victorian enthusiasm for the Manchester brewer's son is conveyed by Henry Steffens, nor does he attempt to explain the significance of the change from "force" to "energy" in physics. He has compiled instead a sober survey of Joule's experiments and theories from 1837 to 1852, together with a discussion of closely related contributions of J.R. Mayer, William Thomson, W.J.M. Rankine, R. Clausius and H. von Helmholtz. Steffens elucidates the path from early experiments on the "electromagnetic engine" to determinations of the mechanical equivalent of heat and formulations of the first law of thermodynamics. Although it provides a clear and accurate account of one aspect of the history of energy conservation, the book suffers from its limited scope. We learn little about Joule's personality or his influence beyond the small circle of scientists mentioned above, and scarcely anything about the concept of energy apart from Joule's rather narrow interpretation of it.

Steffens' most interesting chapter is the one dealing with Joule's rough translation, in his notebook, of Mayer's 1842 paper; he argues that Joule knew of Mayer's work before 1844 and was thereby led to perform the experiments on rarefaction and condensation of air that yielded his third value for the mechanical equivalent of heat. But aside from this, Steffens makes very little use of documents, even those already published (for example, by A.L. Hatton and L. Rosenfeld in 1956, and by J.T. Lloyd in 1970).

This book is almost identical to the author's 1968 dissertation, with the addition of four pages on the paddle-wheel experiment and the deletion of some material on Mary Somerville and W.R. Grove in chapter 6. Much has been written on nineteenth-century physical science during the past decade and as a result historians of science have not only a different view of the development of energy concepts but an enhanced interest in philosophical and sociological questions. Steffens mentions some of the relevant publications in his notes but has made few substantive changes in his text. Perhaps most serious is his failure to take account of John Forrester's important article on the chemical background of Joule's work (*Studies in History and Philosophy of Science*, 1975). Ten of the 22 items in Forrester's "Joule bibliography" are missing from Steffens' bibliography (users of the latter should be warned of a mixup of lines of type on pages 165-66).

It is necessary to criticise two features which this book shares with an increasing number of scholarly monographs. First, if notes must (because of the deterioration of printing technology) be placed at the end of the book instead of the foot of the page, they should be keyed to the text pages so one does not have to find out what chapter one is reading in order to locate its notes. Second, the index should cover the notes as well as the text; in this case it doesn't even cover the text adequately (for example, Aepinus has no entry).

Stephen G. Brush teaches history of science at the University of Maryland, College Park.

Liquid crystalline materials

Liquid Crystals and Biological Structures. By G.H. Brown and J.J. Wolken. Pp. 187. (Academic: New York, San Francisco and London, 1979.) $19; £12.35.

IT is surprising that many distinguished scientists, including Bernal in 1933 and Needham in 1950, should have pointed out so early the importance of the liquid crystalline state for biological systems. Yet it was only in the early 1960s that a major attempt was made to examine experimentally the liquid crystalline properties of biological molecules. Nowadays when so many scientists have contributed to the study of phospholipid-water systems to provide insight into biomembrane structure and function, it is interesting to remember that a great deal of the basic fundamental work — for example, phase transitions, phase diagrams, fluidity, bile salts and cholesterol effects — was carried out as recently as the 1960s. When we further note that myelin figures were first observed by Virchow in 1854 it is interesting to consider the socio-economic technological factors which held up the study for so long of these important liquid crystalline lipid-water systems.

Brown and Wolken remind us of this in the present book. They examine the basic properties of liquid crystalline materials and include a discussion of the various classifications, including nematic, cholesteric and smectic liquid crystals. Thermotropic and lyotropic liquid crystal and the neat soap phase important to the detergent industry is shown. The optical properties of liquid crystals are also adequately but briefly described. These chapters I found neat, and useful. However, the later chapters dealing with the relationship of these fundamental properties of matter to the biological structures are less satisfactory.

The authors include chapters on the cell, photoreceptor structures (that is, chloro-photoreceptor structures, that is, chloroplasts and the eye, fibrous protein structures and effectors, and biomembranes. They also include applications to medicine, such as temperature scanning and diseases. I found these biological chapters a little too superficial for my taste. I would have preferred some better examples of how important an understanding of liquid crystals has been for their biological implications — for example, the way in which thermotropic phase transitions which occur in pure phospholipid-water systems are clearly observed in some natural biomembranes. The use of liposomes as potential pharmacological capsules and the formation of gall-stones are also given only passing reference, and yet these are interesting, useful and important applications of the study of liquid crystalline substances to biology and medicine.

As an overview providing a stimulus for a student or young research worker the book may be valuable. It is clearly written with good diagrams and printing. I observed only a few obvious typographical errors.

Dennis Chapman

Dennis Chapman is Professor of Biophysical Chemistry at the Royal Free Hospital School of Medicine, University of London, UK.

obituary

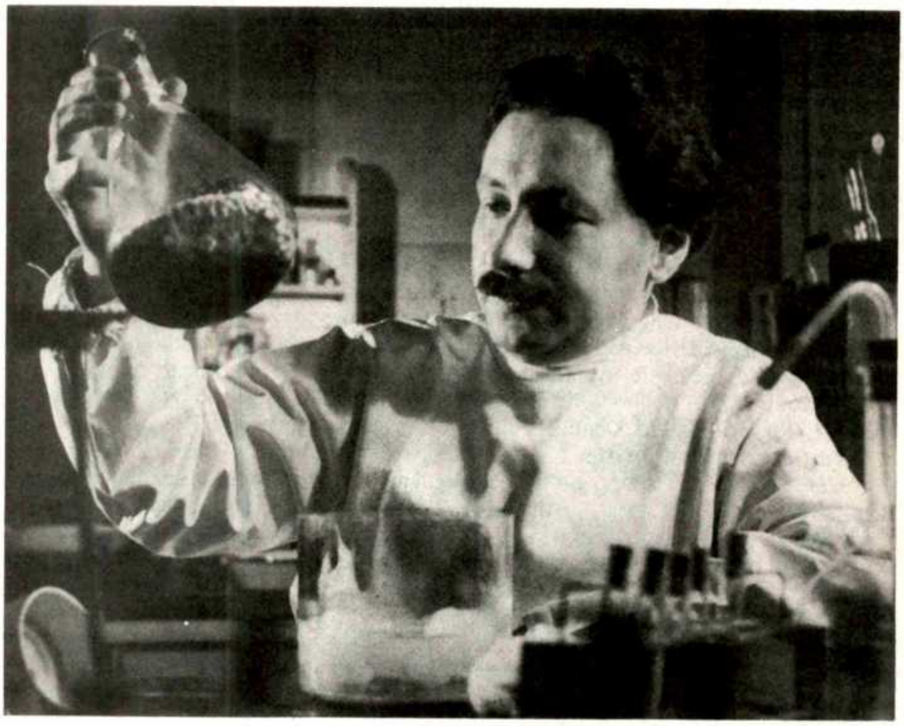
Sir Ernst Chain, 1906-1979

Sir Ernst Boris Chain, who received the Nobel Prize for Physiology and Medicine with Fleming and Florey in 1945, for the discovery and isolation of penicillin, died on 12 August 1979 while on holiday at his country home in Ireland.

He was born in Berlin of a Russian emigré father and a German mother. On 30 January 1933, Chain left his native Berlin to escape from the mounting evils of Nazi Germany. He arrived in London with little but hope and a determination to follow one or other of his great passions — music or science. After a short interlude at University College London, Chain had the good fortune to be recommended by J.B.S. Haldane to Sir Frederick Gowland Hopkins, then Head of the Sir William Dunn School of Biochemistry at Cambridge. Chain was overjoyed with this unexpected opportunity which he seized eagerly: the die was cast on the side of science rather than music.

The topic which engaged Chain's interest was the biochemical basis of the neurotoxic effects of snake venoms. At Cambridge, Chain found that some of the most potent venoms were able to inhibit alcoholic fermentation and glycolysis when added in very small amounts to cell-free extracts. Further studies showed that this was due to destruction of an essential coenzyme by simple hydrolysis. This approach of biological observation followed by biochemical explanation was symptomatic of Chain's scientific philosophy which he followed consistently through 45 years of amazingly diverse achievements.

After two years of working with 'Hoppy', Chain was approached by Professor Howard Florey with an invitation to join Florey's staff at the Sir William Dunn School of Pathology at Oxford. Florey had no biochemical training but he did have an awareness of the importance of biochemistry in the understanding of all biological sciences and in particular of his own field of experimental pathology. Florey drew Chain's attention to an observation by Fleming in 1924 concerning the lytic properties of tears, nasal secretions, and egg white on bacteria. Such a problem — to study the biochemical mode of action of a powerful bacteriolytic agent — was typical of the Chain approach. He was able to show that the lytic properties were due to lysozyme which acted upon a bacterial polysaccharide.



Chain in Oxford, c. 1940

While preparing this work for publication in 1937, and arising from discussions with Florey, Chain stumbled upon the concept of growth inhibition by bacteria, fungi and yeasts acting on one another, including Fleming's neglected original report on the bacteria-inhibiting properties of *Penicillium notatum*. Upon starting their systematic investigation of the antibacterial substances produced by micro-organisms, Florey and Chain were immediately embarassed by a severe shortage of funds compounded by the refusal of the Medical Research Council to fund the work. One day in the autumn of 1937, Chain received a message from Florey stating that in view of the fact that the department had an overdraft of £500 no further equipment of any kind was to be ordered — not even a glass rod!

This experience had a profound effect on the young, enthusiastic Chain who was impatiently waiting to unleash his energies on the new problem of explaining in chemical terms how bacterial growth was inhibited. The unsuccessful approach to the Medical Research Council reinforced his suspicions about university and government financial support. Since that day, he never allowed himself to become wholly dependent for research funds on political largesse, however respectable its facade. Undeterred by this initial setback, Chain discussed with Florey a grant application to the Rockefeller Foundation to cover the costs of the proposed programme for a number of years, so that financial stability could be ensured. To Chain's great delight, the Rockefeller Foundation were sympathetic towards biochemical research and granted him $5,000 for five years.

The penicillin story is well known as it culminated in a Nobel Prize for Chain, Fleming and Florey in 1945. Chain was not the type to rest on his laurels. He was incensed by the refusal of the MRC and Oxford University to consider any form of patent protection for penicillin which was subsequently developed commercially in America. Chain also became increasingly frustrated by the problems of obtaining adequate facilities for the fermentation of micro-organisms on a semi-industrial scale. The methods used initially to provide impure penicillin for laboratory studies and even clinical trials were crude. Chain was very outspoken about the amateurish approach in Britain which he contrasted with the facilities available in the USA. He campaigned vigorously at all levels, for fermentation pilot-plant facilities, but he was met by the implacable inertia of the Establishment who made it very clear that such facilities were a matter for industry and had no place in an academic ivory tower. Chain poured scorn on the view that the size of the reaction vessels should determine whether the biochemical problem to be investigated was 'pure' or 'applied'. In the true British spirit of compromise, Chain was finally offered a single fermenter of moderate dimensions. Chain's reply was to ask if an organic chemist would be prepared to limit himself to the use of one Erlenmeyer flask!

More in sorrow than in anger, Chain accepted in 1948 an invitation to organise a department of biochemistry at the Italian State Institute of Health in Rome. The temptation was made irresistable by the promise that in Rome, an International Centre for Chemical Microbiology containing the controversial fermentation pilot plant with extraction and purification facilities would be made available. The magnificent facilities and the collaborations with Ballio, Dentice, Falini, Marotta (the Director of the Institute), Pocchiari and his colleagues, produced a rich harvest of publications in the new science of chemical microbiology and on the biochemical mechanisms of hormonal control. A constant stream of scientific visitors passed through Chain's laboratories in Rome, so that at any one time at least half-a-dozen different nationalities were represented.

At the start of his Italian era Chain married Anne Beloff in 1948. His wife, who had trained under Sir Rudolf Peters and Baird Hastings, had an active team of collaborators in Rome investigating the mode of action of insulin. During this period the Chains were delighted by the birth of their three children — Benjamin, the eldest son, and then twins, Judith and Daniel.

In 1940 Abraham and Chain had identified the enzyme penicillinase, which inactivates penicillin and which is produced, with great foresight, by numerous bacteria. Chain felt that the affinity of penicillin for this bacterial enzyme could be altered if the penicillin molecule could be chemically modified. Enormous effort had already been expended in the pharmaceutical industry in the search for chemical precursors acceptable to the *Penicillium* mould in the hope that novel penicillins with useful properties would be biosynthesised. Of these, phenoxymethylpenicillin (penicillin V) had turned out to be acid stable and useful clinically because of its absorption after oral administration. Apart from this limited success, some disillusionment had set in regarding the prospects of obtaining novel penicillins, and many laboratories had turned their attentions to more promising areas of antibiotic research. Chain's idea was to improve upon nature by persuading the mould to grow *p*-aminobenzyl-penicillin and then using the chemically reactive amino group for further man-made chemical modifications.

Chain was approached in 1954 by the then Chairman of the Beecham Group, Henry Lazell, on the advice of the late Sir Charles Dodds, with a view to advising Beechams on entering the antibiotics field. Chain's enthusiasm and drive so impressed Lazell that Beechams soon found themselves with a fermentation pilot plant looking remarkably like the one in Rome, and a research programme aimed at modifying *p*-aminobenzyl-pencillin. A small team of scientists was sent to Rome by Beechams while the fermentation plant was being erected. During their stay in Rome in 1956, an interesting difference in the results of two assays of the crude microbial culture fluids was noticed. The chemical assay based on the behaviour of the fused thiazolidine-β-lactam ring consistently gave higher results than the bioassay which required the full penicillin molecule for biological activity. An explanation of this finding followed when the team returned to Beecham Research Laboratories in 1957 when they demonstrated that the discrepancy was due to the presence of the penicillin nucleus (6-aminopenicillanic acid) which was subsequently isolated and characterised, (*Nature*, **183**, 257, 1959). The gateway was now open to an enormous variety of chemically modified derivatives beyond all the original expectations based on the limited synthetic variations possible with *p*-aminobenzyl-penicillin.

The focal point of antibiotic research had moved back to England, and this coincided with a worsening of the political situation in Rome. In the course of a visit to Rome in 1958, Professor P.M.S. Blackett discussed with Chain the possibility of setting up at Imperial College, London, a comprehensively equipped biochemistry department modelled along the lines of the facilities available at the Institute. A further visit by the then Rector, Sir Patrick Linstead, led to a tentative proposal that Chain should return to Enland to re-establish biochemistry at Imperial College where the chair had been vacant since Chibnall left for Cambridge in 1943.

The cost of all the fermentation equipment, instrumentation, electrical and mechanical workshops, required to support and service the complex chemical microbiological research and metabolic biochemical investigations to be undertaken by Chain, was formidable and unheard of in the academic world outside the realms of nuclear physics. The scheme was shelved. However, Chain accepted the challenge of an apparently insoluble difficulty and campaigned vigorously to find independent funds for this imaginative project which complemented the already very strong chemical and chemical engineering interests of Imperial College. As a result of Chain's efforts and Linstead's encouragement, the Wolfson Foundation provided £350,000 to establish the new Wolfson Laboratories, the Science Research Council granted £110,000 in support of fermentation research, and the Fleming Memorial Fund granted Chain £50,000 for basic medical research. Chain had not forgotten the lesson of the forbidden glass rod at Oxford!

Chain returned to take up his new appointment in October 1964 and the new laboratories were completed in the summer of 1965. The Medical Research Council had buried the hatchet by establishing a Metabolic Reactions Research Unit under Chain. Dr Anne Beloff-Chain also continued her studies on insulin and the control of carbohydrate metabolism in the new department as Reader in Metabolic Biochemistry. The financial independence which Chain secured from the very conception of the new department did nothing to endear him to the administrative establishment which found him unimpressed by exhortations to economise in lean years. Minor officials in the Science Research Council and University Grants Committee secretariat found their cautious criticisms of Chain's eminently unreasonable demands quoted, or even possibly misquoted, by Chain in direct conversations with the Treasury or the Prime Minister (according to availability). It would be wrong however to give the impression that Chain was a mere irascible crusader against bureaucracy. He had an affectionate regard for his circle of friends with whom he loved to share musical evenings in which their active participation was expected. He was devoted to his family and all visitors, however distinguished, were put aside, albeit temporarily, whilst Chain greeted his sons and daughter when they called in to his office on their way home from school.

The premature death of Sir Patrick Linstead was a sad personal loss to Chain and a watershed in the fortunes of the department. The sympathetic understanding which Chain had enjoyed with Linstead was irreplaceable and the special relationship of the department, because of its high level of collaboration with industry and support by charitable institutions, became almost an embarassment in inter-college negotiations for funds.

Chain's knighthood came as something of a surprise in 1969 — not, of course, because of any doubts about his quite exceptional personal achievements over 35 years, but because his deliberate policy of rocking Establishment boats had made a deep impression in what are termed 'influential quarters'. It says something for the British political system that his scientific genius finally triumphed over his political reputation, even though 20 years earlier his election to Fellowship of the Royal Society had been delayed for several years.

After his retirement from the chair at Imperial College in 1973, he became Emeritus Professor. He continued to travel widely, aided by his ability to lecture in five languages. Honours and decorations came from many Universities and Governments including France, Italy and Japan, and Chain continued his long, active association with the Weitzman Institute as a Governor.

An abiding memory for his family and friends must be the marvellous occasion in 1976 when Sir Ernst was guest of honour at a dinner held at the Middle Temple Hall to mark his 70th birthday. A crowded scientific programme had been given at the Royal Society over the preceding two days by his closest collaborators. This programme reflected Sir Ernst's research contributions in food technology and non-specific immunity as well as microbial and physiological biochemistry. Fortuitously news came through of his eldest son's first class honours in zoology at Cambridge. After dinner and the speeches (Sir Ernst almost lost for words for once), the entertainment for the distinguished international audience was opened by Sir Ernst and Benjamin Chain playing piano duets with great panache and empathy — a fitting reminder that the gain of science and medicine from the work and life of Ernst Chain was a loss to the concert hall and the world of music.

K. R. L. Mansford

Sir Harry Champion

SIR HARRY CHAMPION, CIE, Emeritus Professor of Forestry in the University of Oxford, died on 19 June 1979. He was born in 1891 and was educated at the Royal Grammar School, Guildford. He was at Kings College, London University, for a year before going up, as a Commoner, to New College, Oxford in 1909. The subsequent award of a college scholarship was the first of his many academic achievements at Oxford. In 1912 he took a first in chemistry, in 1913 a first in botany and in 1914, under William Schlich, a Diploma in Forestry with distinction.

In 1912 he was accepted as a probationer in the Indian Forest Service and after spending a year in the United States on a Carnegie Travelling Scholarship to study entomology he went to India in October 1915.

Champion was appointed Assistant Conservator of Forests in the United Provinces, where P.H. Clutterbuck, later Inspector General of Forests, was Chief Conservator. At an early stage in his career he demonstrated clearly his versatility. In 1916 he was Acting Forest Entomologist at the Forest Research Institute, Dehra Dun, and in 1921 Silviculturist for the United Provinces. As a District Officer he compiled a check list of the fauna of the West Almora Division and also effectively modified the condensing equipment on plant used to distill tar from Chir pine. For the latter he was commended by the Governor of the Province. He was mentioned in other reports for extracting the maximum amount of wood from a very difficult location. At this time he also showed that twisted fibre in Chir pine, a very damaging defect of this species, was a heritable character and not an effect of site conditions.

For the academic year 1924/25, while on leave pending retirement, he held the post of Silviculturist under Troup at the Imperial Forestry Institute, Oxford. In 1925 he married Chrystal Parsons, the grand-daughter of an Indian Army officer and decided to return to India — a momentous decision.

From 1925 until 1936 Champion was seconded to the Department of Education, Health and Lands of the Government of India and appointed Silviculturist at the Forest Research Institute, Dehra Dun. As Central Silviculturist he carried out research in a great variety of silvicultural projects, including natural forest regeneration and the establishment of plantations, as well as engaging in the preparation of yield tables and entomological problems.

He travelled extensively in India, and visited Burma and the Andaman Islands. In 1934/35 he was loaned to the Government of Ceylon to advise on forestry. From his experimental work and travelling he acquired an unparalleled knowledge of Indian forestry. During this period he also toured in the United States, Canada and the Far East. He visited most of the European forest research establishments and established himself as a forester of international repute.

In 1937 Champion returned to the United Provinces where he held the posts of Divisional Forest Officer, Conservator of Forests and Conservator of Working Plans acquiring experience of forest administration at senior level. He seemed destined to go to the top in the Indian Forestry Services, but in 1940 again changed the course of his career by accepting the Chair of Forestry at Oxford and the directorship of the Imperial Forestry Institute, as successor to Troup.

Champion's first notable achievement at Oxford was the establishment, in 1944, of an Honours School of Forestry. As Professor of Forestry he was *ex officio* Consultant Director to the Commonwealth Forestry Bureau and provided for the first Director, J.W.B. Sisam, and later Henry Ford Robertson, encouragement, advice and support to establish that most useful and efficient organisation. He also strengthened the scientific basis of teaching and research in forestry by the appointment of biological scientists. Between 1940 and 1959 he travelled extensively with forestry classes on the continent, on advisory missions and lecture tours to most of the British colonies, and to attend international conferences. His experience in forestry was then world wide and he continued to make best use of it by writing and advising.

After his retirement in 1959 he was appointed Emeritus Professor in 1960 and until 1967 undertook further advisory missions and consulting assignments. In 1962/63 he was engaged by the Government of India to revise the silvicultural textbooks he had written when at Dehra Dun and had a similar assignment for the Government of Pakistan in 1963/64.

Champion published work, mainly in the Indian Forest Records, on every aspect of forestry, including research methods, statistics, working plans and ecology as well as silviculture. His interest in research methods is apparent from his *Silvicultural Research Manual for India, Vol.I: General*, and *Vol.II* (with I.D. Mahendru): *Statistical Code*, 1931. The results of his experimental work and his general observations were incorporated in a *Manual of Indian Silviculture* (with Sir Gerald Trevor) which has now been revised twice (in 1968 with S.K. Seth). In 1965, together with C.M. Khattak and S.K. Seth he prepared a similar manual for Pakistan. Of necessity, most of his time was devoted to matters of immediate and practical importance, but he was very concerned about the scientific basis of forestry and his *Forest Types of India and Burma* (1931, revised with S.K. Seth in 1968) is a major contribution to forest ecology.

Champion's work in India was acknowledged in 1941 by the award of Companion of the Order of the Indian Empire and his scientific achievements by an Oxford DSc in 1950. For his services to forestry in general he was made a Knight Batchelor in 1956. He was chairman of the Commonwealth Forestry Association from 1959 to 1961, president of the Society of Foresters of Great Britain in 1958 and 1959 and an honary member of many national forestry societies. In 1969 he was given the Fernow Medal, awarded jointly by the American Forestry Association and the German Forestry Society.

Twenty classes of Oxford undergraduates and hundreds of foresters from every part of the world have been entertained in unique style by the Champions at Windrush. Some of us that were members of his earlier classes have further reason to be particularly grateful to them for many other kindnesses, among them dispensation to bring, what Chrystal Champion called our "probationary forest wives", on field tours.

Finally it is my privilege to put on record the immense contribution made by Chrystal Champion to the life and achievements of Harry Champion. She was keenly interested in his work, shared his fondness for travelling and perhaps persuaded him to return to India. It was a perfect match and good for forestry.

APPOINTMENTS VACANT

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

SCHOOL OF PATHOLOGY

MEDICAL LABORATORY SCIENTIFIC OFFICER HISTOLOGY

A skilled, experienced histology MLSO required as soon as possible to join a research team studying carcinogenesis in vitro in organ cultures. Preference will be given to someone able to section plastic embedded- as well as wax embedded-material for high resolution histology. Candidates should be Associates of the IST, IMLT or equivalent. The appointment is for one year initially, renewable for a further two. Salary in the range £4,122 to £5,301 depending on age and experience.

Please send applications, with curriculum vitae and the names of two referees to Dr R.M. Hicks, School of Pathology, The Middlesex Hospital Medical School, Riding House Street, London W1P 7LD, by 8 November, 1979.
3555(A)

POSTDOCTORAL RESEARCH ASSISTANT

The successful applicant will have expertise in transmission electron microscopy and a PhD in Metallurgy & Materials Science or in Physics. The project is to study (using electron microscopy; techniques to include hot-stage, X-ray analysis, high resolution and high voltage) the nucleation, microstructures and growth kinetics of intermetallic compounds in the reaction layers which grow during the fabrication and/or heat-treatment of composite A15 superconductors. There will be close collaboration, in an interactive programme, with an existing group investigating and optimising superconducting properties and with an industrial scale fabrication facility at Harwell. Prior research experience involving superconductors is not required.

Salary is on S.R.C. scales and the appointment is for three years commencing from 1st October, 1979 or as soon as possible thereafter.

Applications, together with curriculum vitae, should be sent to Dr J.E. Evetts or Dr E.R. Wallach at the above address.
3551(A)

Section Head Medicinal Chemistry

The Research & Development Division of G. D. Searle & Co., located in north suburban Chicago, has an immediate need for a Section Head within our Medicinal Chemistry Department. As principal scientific expert, leader and manager, you will assume responsibility for directing the entire Medicinal Chemistry research program in the area of gastrointestinal disease, in close cooperation with the head of gastrointestinal pharmacology. The qualified candidate will possess a Ph.D. in Chemistry plus 10 years of experience in the pharmaceutical industry, or equivalent experience in medicinal chemical research. Proven managerial skills are essential.

We offer a competitive starting salary, comprehensive benefits and the opportunity to contribute your talents to our overall research efforts.

For confidential consideration, please submit your curriculum vitae complete with salary requirements to:

L. Kedzior

Research & Development Division

SEARLE

ROYAL POSTGRADUATE MEDICAL SCHOOL

DEPARTMENT OF MEDICINE

POST-DOCTORAL IMMUNOLOGIST

required for work on the role of complement in induction of immunological responses. The project is supported by the Medical Research Council until October 1980 but there will be a continuing opportunity in the Unit for a suitable individual. For further details please contact Dr M.B. Pepys, Immunological Medicine Unit, Department of Medicine, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS or telephone 743 2030 extension 258.

Salary up to £5199 plus £740 London Allowance.

Application forms are available from and should be returned to the Personnel Office, Royal Postgraduate Medical School, 150 Du Cane Road, London W12 0HS quoting reference number 2/220.

METEOROLOGIST

This is a two-year teaching and research position in the Atmospheric Science program of the Department of Land, Air and Water Resources. The person selected will have a doctorate in meteorology or in atmospheric science or a doctorate in a related science plus professional meteorological experience. The incumbent will be expected to teach a total of three quarter courses in one or more of the areas: Atmospheric Physics, Air Pollution Meteorology, Synoptic Meteorology and Dynamic Meteorology and to support one or more of the ongoing research activities within the department. These include the study of large-scale air-sea interaction, marine and continental planetary boundary layer dynamics, and the modelling of mesoscale flows in complex terrain. Research support will be provided by the department. This position is at the Assistant Professor level and carries a 12-month salary of $19,700 and up, depending on qualifications. The position becomes available immediately, with the expectation that the person selected will be available for service on or before January 1, 1980.

Applicants should submit a vitae, statement of teaching and research experience and interests, undergraduate and graduate transcripts, list of publications, reprints, and names and addresses of at least three references, to be sent to John J. Carroll, Meteorologist Search Committee, Department of Land, Air and Water Resources, University of California, Davis, California 95616, telephone (916) 752-3245/1406. Closing date is October 15, 1979.

The University of California is an Affirmative Action/Equal Opportunity Employer.

THE QUEEN'S UNIVERSITY OF BELFAST
LECTURESHIP IN ZOOLOGY

Applications are invited for a post of lecturer in the department of Zoology tenable from 1st April 1980 or such other date as may be arranged. Applicants with some experience in any aspect of Cell Biology preferred but other fields of Zoology will be considered.

Initial placing, which will depend on experience and qualifications will be made at one of the first three points on the scale (under review) for lecturers: £4,335, £4,623, £4,911 rising to £8,994 with contributory pension rights under the FSSU or USS.

The appointment will be subject to a period of probation of up to three years in duration. Further particulars may be obtained from the Personnel Officer, The Queen's University of Belfast, BT7 1NN, Northern Ireland. Closing date: 30th November, 1979. (Please quote Ref. 79/N) 3581(A)

UNIVERSITI SAINS MALAYSIA
SCHOOL OF MEDICAL SCIENCES

pplications are invited for the posts of ofessor in the fields of (1) Anatomy,) Physiology and (3) Biochemistry and cturers in the fields of (1) Pathology,) Pharmacology, (3) Physiology,) Anatomy, (5) Parasitology,) Clinical Biochemistry and (7) Medical icrobiology.

Qualifications/Experience: Candidates r the post of Professor should have BBS/PhD degree with wide experience in field of teaching and research. They ould also have some outstanding public-ons to their credit. Candidates for the st of Lecturer should have MBBS/PhD gree with an interest in undergraduate ching and research. (Clinical staff will required to undertake patient care duties the Teaching Hospital and those with stgraduate specialist qualifications and ry out clinical duties will be eligible for a ecialist allowance).

Salary Range per annum: Professor: m M$35,580 to M$40,380; Lecturer: m M$15,420 to M$29,100. Other efits: return passage, excess baggage istance, paid annual leave, free medical efits for staff and family and gratuity at ½% of total monthly salary and car loan ilities. Tenure: On contract for three rs renewable if necessary.

Applications containing full personal ticulars and current salary to be warded to the Registrar, Universiti ns Malaysia, Minden, Penang, before November.

W459(A)

CHAIRPERSON OF BIOLOGY DEPARTMENT

Northeastern University invites applications for chairperson of biology, to start summer or fall 1980. Department has 21 full-time faculty and 50 more teaching, research, and support staff. It offers undergraduate major; provides courses for undergraduate professional programs; and conducts research and graduate programs in botany, zoology, microbiology, ecology, cell biology, animal physiology, and marine biology. Facilities include more than 35 laboratories, aquarium, animal rooms, animal-care center, EM center, VAX 11/780 computers with departmental terminals, vertebrate museum, herbarium, and large greenhouse. Department is affiliated with university's Marine Science Institute at Nahant. Successful candidate must have excellent research and teaching credentials; administrative experience is desired. Closing date is 30 November. Send resume with description of ongoing research, funding record, and teaching experience, with names of five references, to: **Biology Chairperson Search Committee, 403 Richards Hall, Northeastern University, Boston, Massachusetts 02115.** *Equal Opportunity/Affirmative Action/ Title IX University.* W477(A)

RESEARCH TECHNICIAN for Department of Physiology. The areas of research being renal physiology and endocrinology. The work involves a variety of biochemical assays and experience in radioimmunoassay techniques would be an advantage. Qualifications required ONC in Med. Lab. Science or equivalent. Salary Scale £3,122 to £3,553 p.a.

Application form from Assistant Secretary, Personnel Office, University of Birmingham, PO Box 363, Birmingham B15 2TT. Ref 429/c/342. 3553(A)

IMPERIAL COLLEGE UNIVERSITY OF LONDON
DEPARTMENT OF PHYSICS
LECTURESHIPS IN PHYSICS
BLACKETT LABORATORY

Applications are invited for a number of lectureships in physics from candidates whose research interests lie in the fields of astronomy, optics and laser physics, solid state physics, spectroscopy or theoretical physics.

The successful candidates will be attached to the appropriate research section within the Physics Department. Salary on the scale £4,333 to £8,992 (under review) with superannuation plus London allowance of £740 p.a.

Applications with curriculum vitae, list of publications and the names of two referees should be addressed to Professor D.J. Bradley, Department of Physics, Imperial College, London SW7 before 8th November 1979.

Applications are invited for a

POST-DOCTORAL RESEARCH ASSISTANTSHIP
OPTICS SECTION

The successful candidate will engage in a theoretical research programme in the field of laser dynamics and non-linear optics. Applicants should hold a Phd degree (or equivalent) or be in the process of completing their doctoral thesis. A reasonable background in theoretical physics is a prerequisite and previous experience in quantum electronics would be an advantage. The appointment will be for two years and the salary will be at an appropriate point on a scale starting at £4,333 (under review) plus £740 London allowance and superannuation.

Applications, accompanied by at least two references, should be sent to Dr G H C New, Optics Section, Department of Physics, Imperial College, London SW7 2BZ. 3522(A)

CSIRO AUSTRALIA
Research Scientist
Division of Mathematics & Statistics
Canberra

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7,000 employees — 2,400 of who are research and professional scientists — located in Divisions and Sections throughout Australia.

FIELD: Applied Mathematics

GENERAL: The Division has a staff of 101 of whom seventy percent are professional scientists. Staff are located at centres and laboratories in capital cities in every state and in some major country centres.

The Division's research in mathematics and statistics includes various aspects of fluid mechanics, statistical mechanics, numerical analysis, optimization, operations research, distribution theory, multivariate analysis, stochastic processes, geostatistics, statistical inference and experimental design. Application of this research to agricultural, biological, environmental and industrial investigations, currently includes modelling of ecological, physical, agricultural, climatological systems, industrial processes and mineral surveys.

Scientists of the Division advise on the mathematical, numerical and statistical analysis of research projects undertaken by other Divisions of CSIRO.

The Division wishes to appoint a senior scientist to head a small group in applied mathematics. The present group leader, Dr J Blake, has just been appointed to the Chair of Mathematics at the University of Wollongong.

DUTIES: The successful applicant will be based in Canberra, and will be responsible for the overall direction of the group of four scientists which is represented in both Canberra and Melbourne.

The group has specific research interests in fluid mechanics, soil physics, theoretical physics in biology, applied stochastic processes and statistical mechanics.

QUALIFICATIONS: A PhD degree or equivalent qualifications with demonstrable research and leadership ability.

SALARY: Senior Research Scientist/Principal Research Scientist — $A20,198 to $A27,212 p.a.

TENURE: Indefinite with superannuation.

Applications IN DUPLICATE, stating full personal and professional details, the names and addresses of at least two professional referees, and QUOTING REFERENCE NUMBER 440/307 should reach:-

The Personnel Officer, Australian Scientific Liaison Office, Canberra House, 10-16 Maltravers Street, London WC2R 3EH, by 24th November 1979

Applications in U.S.A. and Canada should be sent to:- The Counsellor Scientific, Embassy of Australia, 1601 Massachusetts Avenue, N.W., Washington, D.C., 20036, U.S.A. 3563(A)

HOWARD UNIVERSITY
COLLEGE OF MEDICINE
FACULTY POSITION IN ANATOMY

The Department of Anatomy is seeking applications for a faculty appointment from individuals with research interest in Reproductive Biology. The candidate should have demonstrated aptitude to develop independent research programs. Applicant should have interest and experience in the teaching of either gross anatomy, histology or neuroanatomy to freshmen medical, dental and graduate students.

Applicant should send curriculum vitae and include a statement of teaching and research goals, bibliography. Reference from three individuals supporting both research and teaching capabilities should be sent to Chairman, Department of Anatomy, College of Medicine Howard University, 520 W Street, NW, Washington, DC 20059.

Howard University is an
Equal Opportunity Affirmative Action Employer

Northern Ireland Forensic
Science Laboratory

Document Examiner (Scientific Officer)

£3,289 – £5,085

Applications are invited for a pensionable post in the Northern Ireland Forensic Science Laboratory, Newtownbreda Road, Belfast.
The officer appointed will join a team of scientists engaged in the scientific investigations of crime throughout Northern Ireland. He/She will be involved in the comparison of handwriting and typewriting and the examination of signatures and documents to detect forgery, alterations, etc. Previous experience in this field would be an advantage.

Applicants must be under 27 years of age at 31 December 1979 and possess:

(a) a 1st or 2nd class Honours degree in a relevant scientific subject; or

(b) an equivalent qualification acceptable to the Civil Service Commissioners.

Exceptionally, applications may be considered from candidates over the age limit who have specialised experience.
Salary will be in the scale £3,289 to £5,085. The salary scale with effect from 1 January 1980 will be £3,591 to £5,486. Starting salary will be related to qualifications and experience.

There are promotion prospects to Higher Scientific Officer £4,727 to £6,211 (£5,097 to £6,737 from 1 January 1980), Senior Scientific Officer £5,876 to £7,864 (£6,332 to £8,705 from 1 January 1980) and Principal Scientific Officer £7,534 to £9,646 (£8,615 to £11,343 from 1 January 1980).

Please write or telephone for an application form quoting job reference SB 362/79/NA to the Civil Service Commission, Rosepark House, Upper Newtownards Road, Belfast BT4 3NR (telephone Dundonald 4585 ext 256). Completed forms must be returned to arrive not later than 8th November, 1979. 3552(A)

English
China
Clays
group

RUBBER TECHNOLOGIST

English Clays Lovering Pochin & Co Ltd, the major operating Company of the English China Clays Group has a vacancy for a Rubber Technologist within its Research and Development Department.

The job involves providing a technical advice service, promoting the Company's products to the rubber industry and maintaining and developing technical contacts with the market. The job holder will also be responsible for specific projects associated with developments in rubber technology.

Candidates should possess a minimum of an HNC and will have at least five years experience of rubber technology. Experience of the rubber markets in Western Europe and extender technology related to the Company's mineral products is also desirable.

The position is based at the Company's well equipped Laboratories at St Austell in Cornwall where facilities provided are excellent.

Competitive salary is negotiable and fringe benefits include Profit Participation, Pension and free Life Assurance, full assistance will be given with re-location expenses.

Applications, together with a curriculum vitae, quoting reference 285B, to: The Personnel Manager, John Keay House, St Austell, Cornwall.

3557(A)

UNIVERSITY OF VICTORIA
Victoria, British Columbia, Canada

DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY:

Applications are invited for the position of

ASSISTANT PROFESSOR

beginning 1 July, 1980. Candidates should have strong teaching and research interests in one or more of the following fields: protein biochemistry, molecular genetics (recombinant DNA), eukaryotic cell membrane receptors. The successful applicant will be required to teach biochemistry at the undergraduate and graduate levels and carry on an active research program. A PhD is required and postdoctorate experience desirable.

Applications with a curriculum vitae, list of publications, a brief statement of research plans, and the names of three references who have been requested to send letters of recommendation should be sent to Prof. A.T. Matheson, Chairman, Department of Biochemistry and Microbiology, University of Victoria, PO Box 1700, Victoria, British Columbia, Canada V8W 2Y2, as soon as possible.
W462(A)

DEPARTMENT OF ANTHROPOLOGY University of Alberta. Position vacancy. The department of Anthropology, University of Alberta, is seeking to hire a physical anthropologist at the level of Assistant Professor. The position is tenure-track and begins July 1, 1980. The present salary is $19,700.00 per annum (subject to 1980 negotiations and can be adjusted upwards according to credentials). PhD required or to be completed by September, 1980. Must be able to teach first-year general anthropology and introductory and advanced courses in physical anthropology, with specialization in human evolution and human osteology. Additional qualifications in comparative osteology and/or human biology sought. The University of Alberta is an equal opportunity employer. Deadline for applications March 1, 1980. Send vitae and names of referees to Dr C.G. Hickey, Chairman, Department of Anthropology, Edmonton, Alberta, Canada T6G 2H4.
W461(A)

MISSISSIPPI STATE UNIVERSITY
DEPARTMENT OF ENTOMOLOGY
ASSOCIATE FULL PROFESSOR

Applications are invited for a full time (12 mos.) appointment with rank of Associate or Full Professor in the Department of Entomology, Mississippi State University. The successful candidate will be responsible for research in pest management on field crop systems with particular emphasis on cotton and soybean insect problems, and for participation in ongoing interdisciplinary research to develop and apply insect-crop pest models and management systems. Teaching and guidance of graduate research will be expected in areas of insect ecology and/or population dynamics. PhD in entomology or relevant life science and experience in field crop research are required.

Experience in modelling and computer programming is desirable. Salary is negotiable and competitive. Application deadline: December 15, 1979. Job available January 1, 1980.

Send resume, list of publications and 3 letters of reference to: Dr E.P. Pieters, Chairman, Search Comm., Entomology Department, Drawer EM, Mississippi State, MS 39762. Mississippi State University is an Affirmative Action/Equal Opportunity Employer. W474(A)

Product Manager-Medical Equipment

Essex to £7,000+car.

My client markets one of the most comprehensive ranges of medical and hospital equipment in the world. Their products are universally respected for their fine design and reliability. The key role of Product Manager for their Intensive Care products provides the link between user and product development, and between sales and manufacturing.

You'll be responsible for keeping the existing product range competitive by close liaison with the medical profession, identifying the need for new products. Short and long term market and production planning is a further important area, as is the training of the sales force and distributors.

We are looking for a mature and level headed man or woman with a solid marketing background in the fields of pharmaceuticals, medical equipment or hospital services. A degree in Science, Engineering or Business Studies would be appropriate, but your experience of modern marketing techniques in a profit conscious organisation is more important. You should be at least 27, and ideally in your early to mid-thirties.

The organisation should have no problems in satisfying your future development needs, and the employment package is realistic, with excellent relocation assistance where appropriate to this relatively low cost housing area.

If you think you fit the bill, talk things over with me, David Woolf on 01-262 0184 or 0376 513513.

Alternatively, send me a brief c.v. to Macmillan Woolf, Personnel Consultants,
North West House, 119/127 Marylebone Road,
London NW1 5PU

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF VETERINARY PATHOLOGY

Applications are invited from holders of good honours degrees in Biochemistry or an allied subject, for the post of Research Assistant/Senior Research Assistant in the Department of Veterinary Pathology. The project is concerned with the intracellular localisation of copper and the isolation of copper binding proteins in chronic copper poisoning. The successful applicant will be eligible to register for a higher degree.

The project is financed for two years in the first instance. The initial salary will be within the range £3,776 to £4,910 per annum.

Applications, together with the names of three referees, should be received not later than 15th November, 1979, by The Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/824. 3572(A)

UNIVERSITY OF HONG KONG

LECTURESHIPS IN PATHOLOGY

Applications are invited for two posts of Lecturer in Pathology. Applicants must hold primary medical or dental qualifications. Possession of an approved higher qualification in Pathology and appropriate experience in the speciality is required for appointment above the bar on the salary scale. Starting salary will depend on qualifications and experience.

Annual salary (superannuable) is: HK$68,580 — 72,060 — 83,340 — 87,240 — 91,320 — BAR 109,920 — 114,840 — 119,760 — 124,680 — 129,600. (£1 = HK$10.70 approx).

At current rates, salaries tax does not exceed 15% of gross income. Housing at a rental of 7½% of salary, education allowances, long leave and medical benefits are provided.

Further particulars and application forms may be obtained from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF, or the Assistant Secretary (Recruitment), University of Hong Kong, Hong Kong.

The closing date for applications is *30th November 1979*. 3561(A)

FACULTY POSITION THEORETICAL NUCLEAR PHYSICS

Indiana University Bloomington

The Department invites applications for appointment as a senior nuclear theorist at the Professor or Associate Professor level with tenure. Candidates should have demonstrated originality and excellence in research. Preference will be given to applicants with the interest and ability to interact with the present theoretical and experimental nuclear physics programs at Indiana University, particularly the intermediate-energy research programs of the Indiana University Cyclotron Facility.

Interested persons should contact Professor Roger G Newton, Chairman, Department of Physics, Indiana University, Bloomington, Indiana 47405. Indiana University is an Affirmative Action/Equal Opportunity Employer. Deadline for applications February 1, 1980. W475(A)

THE UNIVERSITY OF PAPUA NEW GUINEA

(Port Moresby)

Applications are invited for the post of

LECTURER/SENIOR TUTOR IN SCIENCE

Goroka Teachers College

The appointee would be responsible for teaching in two of the following areas: Physics, Geology or Chemistry in the Science Department and would also be involved in some general science teaching. Applicants should hold an appropriate degree and a teaching qualification. Salary Scales: Lecturer K13300 pa, Senior Tutor K11450 pa, (£1 sterling = K1.55). Family passages, baggage allowance; 3 year contract; 24% gratuity of which 5% is taxable; research support; overseas leave; education allowances; medical scheme.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Secretary, Box 4820, University PO, Papua New Guinea by 14 November 1979.

Applicants resident in the UK should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 3542(A)

University of Petroleum and Minerals

Dhahran, Saudi Arabia

Crystallographer

A Crystallographer is sought to work as a research associate with a distinguished Chemistry Professor on the structure of organic phosphorus compounds. Applicants should have a Phd plus some experience in chemical crystallography and should also have programming knowledge. Facilities available include a CAD-4 Automatic Diffractometer with a PDP 8/A Computer, a Weissenberg Camera.

Minimum regular contract for two years, renewable. Competitive salaries and allowances. Air conditioned and furnished housing provided. Free air transportation to and from Dhahran each two-year tour. Attractive educational assistance grants for school-age dependent children. All earned income without Saudi taxes. Ten months duty each year with two months vacation paid.

Apply with complete resume on academic and professional background, indicating home and office addresses, telephone numbers and date of availability for employment, together with three references and with copies of degrees and transcripts to:

Dean of Faculty and Personnel Affairs,
University of Petroleum and Minerals,
PO Box 144, Dhahran, Saudi Arabia.

3548(A)

Research Opportunities in Pharmacology/ Biochemistry

As a result of the recent expansion of our R&D facilities two new posts are available in the Pharmacology Department at the Wyeth Institute of Medical Research, Taplow, near Maidenhead. The successful candidates will join a team of scientists working to define the actions of drugs in mental disorders. One of the applicants will contribute to these studies by assisting in the design and application of biochemical techniques for defining the mechanics by which drugs act within the central nervous system. The other will assist in the development and use of behavioural tests for investigating psychoactive drugs.

The new posts will be of interest to recent graduates with good honours degrees in biochemistry or pharmacology and to those who have some special training in the techniques of psychopharmacology.

The modern laboratories are situated in a pleasant rural setting in Berkshire.

Applicants should send a brief but comprehensive curriculum vitae to:

Miss C. Bradshaw, Personnel Officer,
Wyeth Laboratories, Huntercombe Lane
South, Taplow, Maidenhead, Berkshire
SL6 0PH. Tel. No. Slough 28311.

Wyeth Laboratories 3585(A)

HEAD TECHNICIAN

£6,597 – £8,691

Department of Viral Products

The Institute's main functions are the standardization and control of biological substances used in human medicine, work which is well supported by research. The Division of Viral Products is a large and active division responsible for research and development work in the control of viral vaccines and associated biological products used in man.

This is an important post which calls for considerable experience in microbiology, general laboratory management, and overall supervision of assistant staff. Previous experience in virology and the safe handling of potentially pathogenic organisms would be an advantage.

Salary on Chief or Senior Chief Scale dependant on qualifications and experience within the range: £6,597 to £8,691.

The Department of Microbiology and Immunology, Washington University, School of Medicine invites applications from highly qualified individuals for an appointment as Assistant Professor.

Applicants should have PhD or MD degrees, 2-5 years of post-doctoral research experience and a commitment to medical and graduate student teaching. Teaching competence should be in pathogenic microbiology; research interests should be in microbiology.

Send curriculum vitae, brief description of research plans and names of three referees to Dr Jospeph M. Davie, Department of Microbiology and Immunology, Washington University School of Medicine, St. Louis, MO 63110 by Nov.1, 1979. Equal Opportunity and Affirmative Action Employer M/F/H.
W401(A)

SANDOZ

Pathology

Sandoz Limited is a major Swiss-based multinational pharmaceutical company with a large, modern and well equipped Toxicology Institute in Basle, Switzerland. We are looking for suitable candidates to fill 2 posts that have recently become vacant in our Pathology Department.

A. Head of Section

Job Description: Overall responsibility for the activities of the Pathology Section which comprises a staff of about 20 members including 4 pathologists (Medical Doctors and Veterinarians). The routine activities of the section include the planning, supervision, evaluation and reporting of the post mortem aspects of chronic toxicity studies conducted on animals, including carcinogenicity tests. Since academic members of the Department are also encouraged to pursue their own research interest and to investigate the mechanisms by which drugs induce their toxicity, the Section Head is also expected to be in a position to contribute and encourage such activities. There will be ample opportunities to attend scientific conferences. The Head of Pathology is directly responsible to the Head of Toxicology.

The Ideal Candidate: Will be 30-45 years of age, possess a medical or veterinary qualification (preferably with a higher degree in Pathology) and will have considerable practical experience of laboratory animal pathology. Administrative ability is required for this position as is excellent written and spoken English. Previous industrial experience and a knowledge of German would be advantageous.

B. Pathologist

Job Description: The planning, supervision, evaluation and reporting of the post mortem aspects of chronic toxicity studies conducted on animals (especially carcinogenicity tests on rats and mice). In addition, the investigation of the mechanism by which drugs induce their toxicity. There will be ample opportunities to pursue individual scientific interests, to attend scientific conferences and for the periodic updating of expertise through stays in external laboratories (universities, etc). The pathologist will have 2 histology laboratories and attendant staff (5 technicians) at his disposal. He will be directly responsible to the Head of Pathology.

The Ideal Candidate: Will be 30-45 years of age and have a degree in Medicine, Veterinary Medicine or an appropriate biological discipline. In addition, he will have experience of laboratory animal pathology, preferably with specialized knowledge of tumor pathology and its diagnosis. Organizational talent is required for this post and previous industrial experience and some knowledge of German would be advantageous.

General Information:

- Removal expenses to Switzerland will be defrayed by Sandoz Ltd.
- The firm runs a contributory pension scheme.
- The Toxicology Institute is located in pleasant rural surroundings some 6 miles from the centre of Basle.

Interviews of suitable candidates for both posts will be held in London in mid-November. Short list candidates will be subsequently invited to Basle.

Applications, which should be made in writing, should be accompanied by a comprehensive curriculum vitae and the names of two referees.

Apply to: The Personnel Department, Ref. 1244, Sandoz Ltd., CH-4002 Basle, Switzerland.

W458(A)

INSTITUTE OF OCEANOGRAPHIC SCIENCES

HIGHER SCIENTIFIC OFFICER/SENIOR SCIENTIFIC OFFICER/PRINCIPAL SCIENTIFIC OFFICER

The Institute has vacancies for a Continental Margin (post 1) and an Experienced Geochemist (post 2).

Post 1 Continental Margin Geologist

The Institute is carrying out research into the structure and evolution of continental margins, both adjacent to the British Isles and elsewhere. The research programme includes the acquisition of geological and geophysical data at sea, the compilation of data from other sources, and the analysis and interpretation of these data. In addition to improving our understanding of the nature of passive continental margins and subsided microcontinents, the data are used to provide advice to government on the geological and geophysical criteria with which continental margins can be defined in the context both of existing and proposed International Law.

The successful candidate will be a geologist or geophysicist familiar with marine geophysical techniques. Additional experience in structural and stratigraphic geology, sedimentology or igneous petrology would be advantageous. The job will involve going to sea on research ships for a month or two each year.

Post 2 Geochemist

The vacancy is in a group engaged in a study of geochemical cycling in the marine environment. The programme includes studies of pore water chemistry, development and use of coring techniques for the collection of minimally disturbed cores in the deep ocean, major and minor element analyses and mineralogical examination of cores from a range of oceanographic areas. Additional work with the objective of assessing the role of sediment components in controlling the migration of heavy metals and actinides in ocean sediments is planned.

An experienced geochemist is required to take charge of the sediment geochemistry aspects of this programme. Several years postgraduate experience in marine geochemistry, including collection of deep-sea cores and chemical and mineralogical analysis, are essential.

The appointments will be as a:-

Higher Scientific Officer (HSO) or Senior Scientific Officer (SSO) for post 1 and Senior Scientific Officer (SSO) or Principal Scientific Officer for post 2 on the following salary scales:

HSO —	present rates	£4,727 to £ 6,211 pa	with 22 days paid
	from 1.1.80	£5,097 to £ 6,737 pa	annual leave
SSO —	present rates	£5,876 to £ 7,864 pa	with 22 days paid
	from 1.1.80	£6,332 to £ 8,705 pa	annual leave
PSO —	present scale	£7,534 to £ 9,646 pa	with 5 weeks paid
	from 1.1.80	£8,613 to £11,343 pa	annual leave

Starting salary may be above the minimum according to qualifications and experience. There is a non-contributory pension scheme.

The Natural Environment Research Council is not a government department but conditions of service are similar to those of the Civil Service.

Applications forms and further details from:- The Secretary, Institute of Oceanographic Sciences, Brook Road, Wormley, Godalming, Surrey, GU8 5UB. Tel: Wormley (042-879) 4141, Ext 272. Please quote reference 79/006/458 for post 1 and reference 79/010/540 for post 2.

Closing Date: 16.11.79. 3543(A)

NEUROBIOLOGY RESEARCH ASSOCIATE

To participate in studies of cellular events in the formation, maintenance, and elimination of nerve-muscle synapses, using primarily electrophysiological and E.M. techniques.

Reply to Dr W.J. Betz, Dept. Physiology, University of Colorado School of Medicine, Denver, CO80262, USA.

The University is an equal opportunity/affirmative action employer. W471(A)

UNIVERSITY OF CAMBRIDGE

CAVENDISH LABORATORY

RESEARCH ASSISTANT in the Theory of Condensed Matter Research Group

Applications are invited for the post of Research Assistant to work in collaboration with Dr J.C. Inkson and Dr M. Pepper on the physics of low density one and two dimensional electron gases in semiconductors. The post is intended for a theoretician who can interact strongly with experimentalists in what is a rapidly developing field.

This project is supported by the SRC. The initial appointment will be for two years and the salary will be in a range to £6,066 p.a. depending upon age and experience. Applications with the names of two referees should be sent before 22 November to The Secretary, Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE from whom further details can also be obtained. 3592(A)

TECHNICIAN for Department of Zoology for ODA Tsetse Fly Project. Duties include routine maintenance of cultures and host animals in addition to general assistance with behavioural experiments. Salary scale £3122 to £3553 p.a. Application form from Assistant Secretary, Personnel Office, University of Birmingham, PO Box 363, Birmingham B15 2TT. Ref 141/C/385. 3546(A)

MICHIGAN STATE UNIVERSITY

POSTDOCTORAL RESEARCH POSITIONS in Environmental Carcinogenesis-Mutagenesis

Openings for research associates with strong background in molecular biology, biochemistry, microbiology, or biophysics to study the relationship between DNA repair, mutagenesis, and oncogenic transformation of human cells in culture by physical and chemical carcinogenic agents. One year with option for renewal for additional years with mutual agreement. Send application, including curriculum vitae, reprints, and letters of recommendation to:

Drs Veronica M. Maher or J. Justin McCormick Co-Directors Carcinogenesis Laboratory-Fee Hall, Michigan State University, East Lansing, MI.48824.

An affirmative action/equal opportunity employer. W467(A)

Immunoparasitologist

Assistant to Associate Professor

WASHINGTON STATE UNIVERSITY

Immunoparasitologist for research and teaching. Opportunities for advancement and tenure consideration after appropriate service. Salary — competitive and dependent upon qualifications. Requirements — PhD and post-doctoral experience which includes training in both immunology and parasitology. An opportunity for an industrious scientist to join a progressive interdisciplinary department.

Contact Robert B. Wilson, Head, Department of Veterinary Microbiology and Pathology, Washington State University, Pullman, Washington 99164. Washington State University is an equal opportunity, affirmative action employer.

In order to assist our efforts to meet affirmative action goals, minority, handicapped, and women candidates are encouraged to identify themselves in their applications. Applications should be received by February 1, 1980.

W472(A)

UNIVERSITY OF TORONTO

SCARBOROUGH COLLEGE

Canada

MATHEMATICS ASSISTANT PROFESSOR

(tenure stream) appointment commencing July 1, 1980. Duties include undergraduate teaching, graduate teaching (at the University's main campus), and research.

Send curriculum vitae including a statement of current research activity and names of three referees to:
Professor John E. Dove, Chairman, Physical Sciences Division, Scarborough College, University of Toronto, West Hill, Ontario, Canada, M1C 1A4. W464(A)

UNIVERSITY OF BRADFORD

LECTURER IN PHYSICS

Applications are invited from suitably qualified physicists for the permanent post of Lecturer in Physics in the School of Applied Physics.

The research interests of the School are in Nuclear Structure Physics and Physical Electronics and an appointment will not be made for research in other areas of Physics.

Salary within the range £4,333 to £8,992 per annum (under review). Further particulars and application forms (to be returned by 30 November 1979) obtainable from the Registrar, Post Ref: PY/L/7X. University of Bradford BD7 1DP.

3565(A)

ANIMAL HEALTH TRUST

SMALL ANIMAL CENTRE

RESEARCH ASSISTANT

Applications are invited from veterinary graduates or other suitably qualified persons for the post of Research Assistant to study the pathology and pathogenesis of duck virus hepatitis and other related diseases of the duck. Field work will be included in this study.

The successful applicant, who will preferably have some experience of avian pathology, will join a team investigating virological and serological aspects of these diseases. Encouragement will be given to register for a higher degree if appropriate.

The initial appointment will be for three years. Starting salary will be on the scale £4,910 to £7,521 p.a. (with USS) according to age and experience.

For further information please contact Dr P.R. Woolcock at the Animal Health Trust, Small Animals Centre, Lanwades Park, Kennett, Newmarket, Suffolk. CB8 7PN. Telephone Newmarket 750543 (0638). Applications to include full curriculum vitae and the names of two referees to be sent to The Director, Animal Health Trust, Lanwades Hall, Kennett, Newmarket, CB8 7PN by November 30th 1979. 3568(A)

PROCESSORS & GROWERS RESEARCH ORGANISATION (PGRO)

Thornhaugh, Peterborough, PE8 6HJ

TECHNICAL OFFICER (A)

Applications are invited from suitab qualified young persons for the above pos which involves responsibility for running small processing laboratory, and allie activities, including involvement in fiel trials of vegetables for canning and quick freezing.

Full details, including job descriptio conditions of employment and applicatio form available on request from th Director. 3570(A)

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL (University of London)

TECHNICIAN 5 (IMMUNOLOGY)

required initially to assist in a project und Dr B. Anderton involving the isolation brain proteins and the production monoclonal antibodies to those proteins.

HNC/degree and experience in prote chemistry, or immunochemistry or tissu culture essential. The appointment permanent and pensionable. Emolumen £3,700 to £4,320 (under review) plus £3 p.a. London allowance.

Application forms and further partic lars from the Establishment Office St George's Hospital Medical Schoo Cranmer Terrace, London SW17 0R Closing date 19th November. 3587(A)

UNIVERSITY OF OXFORD

DEPARTMENT OF BIOCHEMISTRY

DEPARTMENTAL DEMONSTRATORSHIP

It is proposed to appoint a Departmen Demonstrator as soon as possible. T salary will be on the scale £3,775 to £5,0 p.a., according to qualifications a experience and with membership of U.S. The appointment is for a period n exceeding 3 years. The successful candida will be expected to take part in depa mental teaching and to conduct his or h own research.

Applications (3 copies) including t names of two referees, should be sent n later than 30th November, 1979 to:

The Administrator, Department Biochemistry, South Parks Road, Oxfo OX1 3QU. 3532(A)

AN FORAS TALUNTAIS

invites applications for a

RESEARCH POST IN REPRODUCTIVE ENDOCRINOLOGY

or a related discipline. The appointment will be for a period of not less than two years and will involve research on the endocrine cause of anoestrus and embryonic mortality in beef cows.

ESSENTIAL: An Honours University Degree or equivalent in a relevant discipline. *DESIRABLE:* (i) a PhD in Reproductive Endocrinology or in a related discipline, (ii) experience of hormone assay methodology.

Application form and further particulars may be obtained from the Personnel Department (ref. R.S.), An Foras Taluntais, Headquarters, 19 Sandymount Avenue, Ballsbridge, Dublin 4, Ireland. Latest date for receipt of completed forms Friday, 30th November, 1979. 3577(A)

CHURCHILL HOSPITAL RESEARCH INSTITUTE

(University of Oxford)

Applications are invited for a BIOLOGIST

o join a research team investigating the ffects of therapeutic doses of x-rays and ast neutrons on normal tissues. The uccessful candidate will be expected to articipate in studies aimed at examining oth physiological and histological hanges in tissues after irradiation. The ost, which is grant aided, is suitable for omeone with a higher degree or equivalent esearch experience.

Further information and applications, ith the names of two referees by 16 ovember, to Dr J.W. Hopewell, hurchill Hospital Research Institute, eadington, Oxford. 3549(A)

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF VETERINARY PATHOLOGY

pplications are invited for the post of ecturer in the Department of Veterinary athology.

Preference will be given to veterinary raduates with interests and training in linical Chemistry, but applications are lso invited from biochemists or recent eterinary graduates contemplating a areer in this field.

The salary scale is £4,333 to £8,992 per nnum.

Applications, together with the names of ree referees, should be received not later an 15 December 1979 by The Registrar, he University, PO Box 147, Liverpool 69 3BX, from whom further particulars ay be obtained. Quote ref: RV/825. 3571(A)

UNIVERSITY OF SOUTHAMPTON

OUTHAMPTON MEDICAL SCHOOL

POSTDOCTORAL SCIENTIST

r a post funded by an MRC Programme rant to Professors G.T. Stevenson and .H. Wright. The work involves immunoemical studies of human lymphoma, ith particular regard to surface immunoobulins and lysosomal enzymes.

Appointment for 5 years in the first stance, on University Research Scale 1A: ,333 to £7,521 p.a.

Further particulars may be obtained om Mrs. P. Vaughan-Smith, Staffing epartment, The University, outhampton, SO9 5NH, to whom plications including the names of two ferees, should be sent as soon as possible. lease quote ref: 1105/R/N. 3589(A)

ST THOMAS' HOSPITAL LONDON SE1

POSTDOCTORAL RESEARCH FELLOW

£5805 — £6252 inc.

To work for 3 years from April 1980 in the Vision Research Unit of the Rayne Institute, on neurochemical transmission in the mammalian retina.

Please write giving full curriculum vitae and names and addresses of two referees to Dr H. Ikeda, Head of Vision Research Unit, The Rayne Institute, St Thomas' Hospital, London SE1 7EH. 3539(A)

UNIVERSITY OF CAMBRIDGE

CAVENDISH LABORATORY

POST-DOCTORAL RESEARCH ASSISTANT

is required for research into the structure of metallic and oxide glasses. Experience in specimen preparation, neutron or X-ray scattering and electron microscopy would be an advantage.

Salary on a scale to £6,066 p.a. U.S.S. membership. Applications should be addressed to The Secretary, Cavendish Laboratory, Madingley Road, Cambridge CB3 0HE and reach him by 22 November. 3593(A)

UNIVERISTY OF GLASGOW

DEPARTMENT OF NEUROLOGY

POSTDOCTORAL RESEARCH ASSISTANT

required for a three year project on myasthenia gravis and the antigenic structure of the human acetylcholine receptor. Experience of monoclonal antibody or tissue culture techniques preferable.

Salary according to age and experience. Applications, giving two referees, to Dr T. Barkas, Department of Neurology, Institute of Neurological Sciences, Southern General Hospital, Glasgow G51 4TF. (041-445-2466 Ext. 8036) 3591(A)

UNIVERSITY OF GLASGOW

LECTURESHIP IN PHARMACOLOGY

Applications are invited from medically and/or scientifically qualified pharmacologists for a Lectureship in Pharmacology. Salary will be within range £4,333 to £6,355 of the Lecturers' scale £4,333 to £8,992, with placement according to qualifications and experience.

Further particulars may be obtained from the Secretary of the University Court, (Room 18), University of Glasgow, Glasgow, G12 8QQ, with whom applications (8 copies), giving the names and addresses of three referees, should be lodged on or before 23rd November, 1979.

In reply please quote Ref. No. 4263/2M. 3579(A)

AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited from suitably qualified persons for appointment to the following positions:

RESEARCH SCHOOL OF PHYSICAL SCIENCES

DEPARTMENT OF ENGINEERING PHYSICS

RESEARCH FELLOWS IN LASER-PRODUCED PLASMAS (Two positions)

Applicants should have a background of research into laser-produced plasmas and would be expected to participate in the existing experimental programmes as well as developing ongoing research projects in this field. Research within the Laboratory is supported by two single-beam Neodymium laser systems with peak powers of several hundred gigawatts. The main research areas are the spectroscopy of laser-produced plasmas and laser-matter interactions including self-focussing, field-gradient force effects, adsorption and reflectance mechanisms, wavelength scaling effects, and ionisation processes. Extensive diagnostic systems, computing facilities and electronic and mechanical engineering workshops are available to support the research.
CLOSING DATE: *31 JANUARY 1980.*

RESEARCH FELLOW IN IMAGE PROCESSING

This position, within an established group in the Department, involves study of image enchancement and analysis techniques (for example, with respet to spectral, temporal and spatial characteristics of LANDSAT imagery) and investigations of new remote sensing applications enabled by improvements in these techniques and in the availability of data.
The appointee would have access to the Department's flexible PD! 11/45 based interactive image analysis system, to the Research School of Physical Sciences DEC system 10 and to the ANU Computer Services Centre UNIVAC 1100/42 computers.
CLOSING DATE: *31 JANUARY 1980.*

RESEARCH SCHOOL OF SOCIAL SCIENCES

'AGEING AND THE FAMILY' PROJECT

RESEARCH FELLOWS/SENIOR RESERCH FELLOWS (two posts)

The School wishes to appoint an applied sociologist and a policy analyst to particpate in a study of the social relations and living arrangements of the aged, with particular emphasis on implications for policy.
Preferably, applicants will have a background in either applied social science or policy analysis. Experience in gerontology, the sociology of the family, survey analysis, or assessment of social welfare or housing programs would be a distinct advantage.
One of the appointees will be expected to take responsibility for co-ordinating the project. This person will be responsible for providing academic leadership, administering the budget, co-ordinating the activities of other staff, and co-operating with related efforts by others in the School and in other universities and institutions.
Further information is available from Dr L.H. Day in the Research School of Social Sciences of the University.
CLOSING DATE: *23 NOVEMBER 1979.*

URBAN RESEARCH UNIT

FELLOW/RESEARCH FELLOW/SENIOR RESEARCH FELLOW

Applications are invited from social scientists and others in related disciplines interested in multi-disciplinary research on Australian cities. Applicants should have a postgraduate degree and, for a Fellowship or Senior Research Fellowship, considerable experience in research.
Preference will be given to applicants interested in research related to public policy.
Up to three appointments may be made.
CLOSING DATE: *16 NOVEMBER 1979.*

Salary-on appointment will be in accordance with qualifications and experience within the ranges: Fellow $A18,990 to $25,441; Senior Research Fellow $A22,755 to $27,143; Research Fellow $A16,291 to $21,265 p.a. Present exchange rate — $A1 : 51p : $US1.12.

TERM OF APPOINTMENT: Fellow — five years with possibility of reappointment to age 65. Research Fellow/Senior Research Fellow — three years with possible extension to five years.
Reasonable appointment expenses are paid. Superannuation benefits are available for applicants who are eligible to contribute. Assistance with finding accommodation is provided for an appointee from outside Canberra. The University reserves the right not to make an appointment or to make an appointment by invitation at any time.
Prospective applicants should first obtain further particulars from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. 3596(A)

POSTDOCTORAL POSITION starting January 1980 to study molecular biology of mammalian mitochondrial DNA. Experience in recombinant DNA cloning and DNA sequencing is desirable but not necessary. Send curriculum vitae, a brief summary of past research and names of references to either Dr P.J. Laipis or Dr W.W. Hauswirth, Department of Biochemistry and Molecular Biology, Box J-245, JHMHC, University of Florida, Gainesville, Florida 32610. *Equal Employment Opportunity/Affirmative Action Employer* W473(A)

RESEARCH ASSOCIATE — POSTDOCTORAL — to work on the organization and transcription of the genes for mammalian low molecular weight RNA's or on the function of these RNA species. Recent PhD with background in molecular biology or biochemistry preferred. Send C.V. and names of three references to: Dr George Eliceiri, Cell Biology Division, Department of Pathology, St. Louis University School of Medicine, St. Louis University Medical Center, 1402 S. Grand, St. Louis, MO 63104, U.S.A. An Equal Opportunity Employer M/F/H. W468(A)

DIRECTOR

Biopharmaceutics, Drug Metabolism, Pharmacokinetics

Ann Arbor, Michigan

The Pharmaceutical Research Division of Warner-Lambert is seeking an outstanding scientist to head a newly constituted group. The new Director will be responsible for a group of 25-30 scientists dealing with absorption, distribution, metabolism and excretion of new drugs.

The successful applicant will have:

- Extensive personal experience with biopharmaceutic and drug metabolism studies in the pharmaceutical industry.
- Complete familiarity with and knowledge of radiochemical techniques both at the synthetic and analytical level.
- Experience and knowledge of sophisticated analytical techniques such as GC/MS and radioimmunoassay.
- A thorough and detailed knowledge of drug metabolism studies in relation to requirements of the FDA and other drug regulatory authorities.
- Management and leadership skills with abilities to motivate staff to a high level of scientific performance and to communicate well.

and be responsible for:

- all absorption, distribution, metabolism and excretion studies carried out in experimental animals with potential new drugs.
- bioavailability, bioequivalence, pharmacokinetic and metabolism studies in human subjects.
- providing an input into the Drug Discovery process from a knowledge of metabolism of known chemical compounds.

The Director of Biopharmaceutics and Drug Metabolism will liaise closely with other scientists in Pharmacology, Chemistry and Toxicology as well as the Clinical Research Group.

The research facilities, located next to the University of Michigan campus in Ann Arbor, Michigan, are among the finest and best equipped in the world and are devoted exclusively to the discovery and development of new drugs.

Join the exciting Research and Development Team at Warner-Lambert in this very key position and enjoy outstanding compensation, benefits and work environments.

Send your resume and salary history/requirements in confidence to:

Mr. D. Misner Personnel Supervisor
WARNER-LAMBERT RESEARCH LABS.
2800 Plymouth Road • Ann Arbor, Michigan 48106

An Equal Opportunity Employer M/F

W479(A)

Warner-Lambert

UNIVERSITY OF OXFORD

PLANT PHYSIOLOGIST

with research experience required to work with the Reader in Soil Science on an ARC project studying root temperature effects on nutrient uptake.

Salary in Grade 1A: £4,333 to £7,521.

Applications, mentioning two referees, to the Administrator, Department of Agricultural Science, Parks Road, Oxford OX1 3PF before 10 November 1979.

3595(A)

UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF MECHANICAL ENGINEERING

RESEARCH ASSOCIATE

Applications are invited for the temporary post of Research Associate for research into new types of gyroscopic instruments. The work is financed by the Science Research Council and will investigate the application of mechanical and electrical characteristics of selected crystals to the precise measurement of angular velocity and displacement. Applicants should be graduates in a relevant branch of applied physics or engineering. Experience in crystal mechanics and electronics will be an advantage.

The post is tenable for up to three years and the initial salary will be in the Range 1A scale: £4,333 to £7,521 per annum, according to age, qualifications and experience. Membership of the appropriate University superannuation scheme will be required.

Further particulars may be obtained from Professor L. Maunder, Department of Mechanical Engineering, The University, Newcastle upon Tyne, NE1 7RU, with whom applications (3 copies), together with the names and addresses of 3 referees should be lodged not later than 16th November, 1979. Please quote reference N.

3558(A)

GUY'S HOSPITAL

MEDICAL SCHOOL

SECRETARY

required as soon as possible to work for Profesor and Unit of Gastroenterology.

Applicants must be competent shorthand-typists. Salary according to experience and qualifications.

Apply in writing, stating age and giving details of qualifications and experience and the names of two referees, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting Ref. G.R.1.

3566(A)

UNIVERSITY OF DUNDEE

Applications are invited for a newly established

CHAIR OF ZOOLOGY

in the Department of Biological Sciences. There is at present one other chair in the Department, the Boyd-Baxter Chair in Biology which is currently held by Professor W D P Stewart, FRS.

Further particulars are available from The Secretary, The University, Dundee DD1 4HN, with whom applications (ten copies or, if posted overseas one copy) should be lodged by November 22nd, 1979. Please quote reference EST/86/79J.

3576(A)

RESEARCH ASSISTANT

Postgraduate Research Biochemist/Physiologist/Pharmacologist required to join a research team investigating various aspects of cardiac biochemistry and pharmacology. Experience in spectrophotometry, tissue metabolite analysis or isolated tissue perfusion would be advantageous. The research unit is located in the new Rayne Institute and appointments will be made through St Thomas's Hospital Medical School.

Applications together with a curriculum vitae should be sent to Dr D J Hearse, The Rayne Institute, St Thomas' Hospital, London SE1.

3550(A)

UNIVERSITY OF SOUTHAMPTON

RESEARCH ASSISTANT — GRADUATE

to join a team working on immunochemical aspects of leukaemia and lymphoma. Appointment funded by MRC, for five years in the first instance.

Salary in range £3,775 to £4,910 p.a.

Further particulars may be obtained from Mrs. P. Vaughan-Smith, Staffing Department, The University, Southampton, SO9 5NH, to whom applications including the names of two referees, should be sent as soon as possible. Please quote ref: 1106/R/N. 3590(A)

ANNOUNCEMENTS

EUROPEAN SOCIETY FOR RADIATION BIOLOGY

The 15th Meeting of the European Society for Radiation Biology will be held at the Medical Faculty of the Erasmus University Rotterdam, the Netherlands from Augus 25 to 28, 1980. Further information can be obtained from the secretary of the meeting Dr J.J. Broerse, Radiobiological Institute TNO, P.O. Box 5815, 151 Lange Kleiweg 2280 HV Risjwijk, the Netherlands.

FELLOWSHIPS

The Weizmann Institute of Science is pleased to announce the availability of the

Charles H. Revson Career Development Chairs and Post-Doctoral Fellowships.

The Revson Chairs are intended for promising young scientists who are eligible for appointment as Senior Scientists at the Weizmann Institute.

The Revson Fellowships will be awarded to promising young scientists within three years after they have received their PhD degrees.

Both categories are intended either for scientists residing in Israel or those who are considering making their residence there. These appointments may commence any time during 1980. The appointments for Revson Career Development Chairs are for a three to four year period. Appointees found suitable at the end of this period, will be invited to continue as permanent members of the Weizmann Institute's scientific staff.

Appointments for Revson Post-Doctoral Fellowships are for periods of one to two years.

Candidates are requested to write for application forms to:

Charles H. Revson Foundation Programme
c/o Academic Secretary
Weizmann Institute of Science
Rehovot,
ISRAEL

COWBURN RESEARCH FELLOWSHIP/ SCHOLARSHIP

Applications are invited from recent graduates with good honours degrees, and postgraduate students holding PhD or quivalent for the above post. The uccessful applicant will join a research group in the Department of Medical Microbiology investigating immune esponses to virus infections. The work will nvolve a detailed study of the nature of the ntibody response to a localised virus nfection in normal and immuno-ompromised hosts and the role of these esponses in limiting virus growth.

The successful applicant will be esignated fellow or scholar, depending on qualifications and experience and the post s tenable for three years. Salary will be on he University scales for Research and nalagous staff with the starting salary in he range of £4,515 to £5,362 including London Weighting.

Further details of the post and the project are available from Professor J.R. Pattison (01-274-6222 Extn. 2480) and pplications should be sent to the Secretary of the Medical School by 10th November 979. 3582(E)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MICROBIOLOGY

RESEARCH FELLOWSHIP

Applications are invited for a three-year MRC-financed research fellowship. Salary will be on the RF1A scale £4333 to £7521, plus superannuation. Starting salary will be up to £5488 according to age and previous (not necessarily related) postdoctoral experience.

The project is to study the chemical changes in virus-infected cells both *in vitro* and *in vivo* by X-ray microanalysis. The work will be carried out in two laboratories under the supervision of Dr J Stephen (Department of Microbiology, Birmingham University) and Dr T.A. Appleton (Department of Physiology, Cambridge University). Full provision has been made for travel between the two institutions and stays of short duration in Cambridge.

Further particulars are available from the Assistant Registrar, Science and Engineering, University of Birmingham, PO Box 363, Birmingham B15 2TT, to whom applications (three copies), including full curriculum vitae and naming three referees should be sent by Friday 16th November, 1979. Please quote reference NM6(r). 3573(E)

UNIVERSITY OF DUNDEE

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a

TEMPORARY LECTURESHIP/ POSTDOCTORAL FELLOWSHIP

in Biochemistry available in the above Department for two years (Lectureship for nine months, followed by MRC Postdoctoral Fellowship for 15 months) from 1 January 1980 (or as soon as possible thereafter).

The successful candidate will be required to undertake teaching duties and to contribute to the research activities of a group studying the genetic deficiency and regulation of hepatic microsomal UDP-glucuronyltransferas and glucose-6-phosphatase.

Applicants should be scientists with an appropriate PhD qualification. Postgraduate and/or up to three years' postdoctoral experience in enzymology, protein chemistry, membrane proteins, and/or immunology would be useful.

Salary dependent on qualifications and experience, but an an appropriate point within the range £4333 to £5488.

Applications (with a curriculum vitae and the names of two referees) should be sent by 15 November 1979 to The Secretary, The University, Dundee DD1 4HN. Please quote Reference EST/91/79H. Professor P.B. Garland, Head of the Department of Biochemistry (telephone Dundee 23181 ext 595) will be pleased to answer informal enquiries.

3575(E)

GIRTON COLLEGE CAMBRIDGE

Applications are invited for a scientific research fellowship open to graduates of any university and tenable for three years from 1st October 1980. The applications should be in the field of Mathematics, Natural Sciences, Geography and allied subjects.

The fellowship is to the value of £3,000 per annum to a candidate with a PhD and £2,750 per annum to a candidate who has not completed a PhD. The fellowship is pensionable under U.S.S.

Particulars are available from the Secretary to the Council, Girton College, Cambridge CB3 0JG to whom applications should be sent by 19th November, 1979. 3503(E)

UNIVERSITY OF ESSEX

FELLOWSHIP

Laser-produced plasmas

An S.R.C. — sponsored post-doctoral Fellowship is available, initially for two years from 1 January 1980, to work under the supervision of Dr T.A. Hall on Rayleigh Taylor instabilities in laser-produced plasmas. The experiments require the development of a high-speed X-ray framing camera and previous experience with high speed electronic streak cameras would be an advantage. Starting salary up to £4,910 per annum on Range IA.

Applications (two copies), including a curriculum vitae and the names and addresses of two referees, should reach Mrs D. Weatherall, Department of Physics, University of Essex, Wivenhoe Park, Colchester CO4 3SQ, from whom further particulars may be obtained, by November 16, 1979. 3562(E)

SRC RESEARCH STUDENTSHIPS

We have two vacancies for post-graduate research students. One in **Medical Physics** to join a group carrying out research in co-operation with the Medical Physics Department of the nearby Singleton Hospital on the *in vivo* detection of elements in the human body using neutron activation analysis; the other to join the **Ionization Physics** research group to work on processes of ionization and attachment in pulsed neutron counters in collaboration with UKAEA, Winfrith. SRC Case Studentships are available for both posts.

Applicants should possess a good Bachelor's or Master's degree from a British University in Physics, Electrical Engineering or related subject, and, if appointed, will be encouraged to register for a PhD degree of the University of Wales.

Further details from Professor J Dutton, Telephone (0792) 25678, Extn 390. 3580(F)

UNIVERSITY OF DUBLIN
Trinity College

POST-DOCTORAL RESEARCH

Applications are invited for a post-doctoral research assistantship to work on the structure and function of tryptophan synthetase in yeast with Dr C Bailey. The enzyme has been purified and shown to be a multi-functional protein. The research will be into the structural integrity, sterochemical relationship and interconnection of the two active sites present and applicants should preferably have experience in protein chemistry and/or enzymology. The project is supported by the National Board for Science and Technology for a period of three years, on a salary scale £4,182 to £4,879.

Candidates should submit a curriculum vitae, together with the names and addresses of two referees to:

The Establishment Officer, Staff Office, West Theatre, Trinity College, Dublin 2. 3545(P)

LEICESTER POLYTECHNIC

SCHOOL OF CHEMISTRY

LEA RESEARCH ASSISTANTSHIP

This is a three year post and the appointee will be registered for a CNAA PhD degree under the supervision of Dr Roger Linford, Reader in Chemistry. Duties will include six hours per week teaching. The project is concerned with fundamental aspects of the behaviour of solid electrolytes and related battery systems intended for heart pacemaker and similar applications. Previous experience in solid state electrochemistry not necessary, but an interest in structural inorganic Chemistry, X-ray powder diffraction or differential thermal analysis an advantage. A good honours degree or equivalent in Chemistry, materials Science or a related subject required.

Commencing salary: £2,913 plus £72 supplement p.a.

Application forms and further details from Staffing Officer, Leicester Polytechnic, PO Box 143, Leicester LE1 9BH. Informal enquiries to Roger Linford, Tel: (0533) 551551 Ext. 2202. 3574(P)

ASSOCIATESHIPS

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF ZOOLOGY

POST-DOCTORAL RESEARCH ASSOCIATE IN MEMBRANE BIOPHYSICS/PHARMACOLOGY

Applications are invited for an SRC-supported post-doctoral associateship commencing 1st January, 1980, or as soon as possible thereafter, to work with Professor PNR Usherwood on single ionic channels in locust muscle membrane gated by amino acid receptors. Ideally the successful applicant will have experience in membrane biophysics or pharmacology and an interest in computing.

The appointment is tenable for one year initially with a possibility of extension for a further year. The starting salary will be between £4,910 to £6,066.

Further details of this vacancy may be obtained from Professor Usherwood.

Applications, including curriculum vitae and the names and addresses of two referees, should be sent to: The Departmental Secretary, Zoology Department, Nottingham University, University Park, Nottingham NG7 2RD. 3559(O)

AWARDS

Research into Renal Diseases in the Tropics

Competitive Award of up to £150,000

The Wellcome Trustees wish to encourage research into diseases occurring in the Tropics which affect the renal system. A competitive award of up to £150,000 is offered for a period of not more than 5 years.

Preference will be given to proposals which demonstrate an interdisciplinary approach and especially those which include sustained collaboration with research centres in the Tropics. This award is additional to the Trustees' normal arrangements for supporting tropical medical research under which smaller grant applications can be considered.

Applications must be submitted on the appropriate form. Please telephone or write (quoting Ref: RDT/N) to:

The Grants Section,
The Wellcome Trust, 1 Park Square West,
London NW1 4LJ. Tel: 01-486 4902.

The closing date for applications is 11th Jan. 1980.

The Wellcome Trust

3556(N)

WYE COLLEGE
(University of London)

Applications are invited for an SRC CASE award held jointly between Rank Hovis McDougall and the Department of Plant Sciences at Wye College.

The award is for work on the physiology of alternative growth habitats in field bean and concerns recent genetic developments for the adaptation of this traditional crop to modern intensive agriculture.

Applicants should have at least an upper second class degree in Agriculture, or Plant Sciences or a related area.

Applications should be made to Dr G.P. Chapman, Department of Plant Sciences, Wye College, University of London, Ashford, Kent TN25 5AH. 3554(N)

COURSES

NATO ADVANCED STUDY INSTITUTE

TIME-RESOLVED FLUORESCENCE SPECTROSCOPY IN BIOCHEMISTRY AND BIOLOGY

A comprehensive course at "state-of-the-art" level on the various techniques, theory, data analyses and applications of nanosecond and polarised nanosecond time-resolved fluorescence spectroscopy will be held under NATO ASI auspices between 16 and 29 March, 1980 at St. Andrews, Scotland. The basic programme is of 34 main lectures to be given by a number of research workers pre-eminent in the areas indicated.

Applications to attend and requests for further information should be sent to Professor R B Cundall, Department of Biochemistry, University of Salford, Salford M5 4WT, UK, applications to arrive before December 15, 1979. Up to 90 places are available for post-graduate and both junior and senior post-doctoral applicants who should append *where appropriate* a curriculum vitae (including references to recent publications in these or allied areas) and, for post-graduates, a letter of recommendation from their supervisor and/or Head of Department. Successful applicants from NATO countries may receive some assistance towards accommodation and travel costs. Depending on response, a small number of places for applicants from non-NATO countries may also be available. 3586(D)

As easy as 1·2·5

If you've been wishing you could get rid of the inconvenience and difficulties of iodinating proteins, here is an easy way to do it. Get our simple, reliable Radioiodination System [^{125}I] – everything you need, ready for your protein.

We've selected a mild reaction method (enzymatic lactoperoxidase) to preserve your protein specificity. We've made sure that there are no contaminants to interfere with proper iodination. And we've tested each lot in a complete iodination procedure.

The ingredients are: Sodium iodide [^{125}I], iodination reagent, sodium phosphate buffer, 1% β-D-glucose to activate the system, and a volatile radioiodine trap.

This system is the new way to make iodination straightforward and reliable. Send for the protocol to start saving time and trouble.

Not for use in humans or clinical diagnosis.

Happy Endings.

Your DNA research should have a happy ending. That's why Miles has developed enzymes that cleave and splice DNA easily and accurately.

All of our restriction nucleases–such as *Eco* RI–specifically cleave DNA within certain well-defined base sequences. And to make sure you're happy with the cleaved ends, we include a sample of lambda DNA for verification of enzyme activity ... so you never risk your research DNA. The results of our stringent specification tests are reported on the chemical credential that accompanies each order. No surprises, no mystery.

And, for recombinant DNA, we have terminal transferase to add dA and dT segments and DNA ligase to splice fragments together.

Restriction nucleases, terminal transferase, DNA ligase. Miles enzymes for happy endings ... and beginnings.

Please supply more information about:
☐ Restriction nucleases ☐ DNA ligase ☐ Terminal transferase
☐ Please send a current Miles Biochemical Catalog.
